Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

THE

MECHANICS' MAGAZINE,

AND

JOURNAL OF ENGINEERING, AGRICULTURAL MACHINERY, MANUFACTURES, AND SHIPBUILDING.

VOL. I.

(NEW SERIES.)

JANUARY TO JUNE, 1859.

EDITED BY R. A. BROOMAN AND E. J. REED.

"No manner of demonstration, or form of interpreting nature, however excellent for defending and sustaining the mind from error and failure, can also provide and supply it with the material of knowledge. But by all who would not guess and divine, but would discover and know, and who desire not to invent buffooneries and fables about worlds, but to inspect, and as it were dissect, the nature of this real world, all knowledge must be sought from *things* themselves. Nor can any substitution or compensation of wit, or meditation, or augmentation, suffice in the stead of this labour, and inquisition, and perambulation of the world; not if all the wit of all men were to combine for the purpose. The labour, therefore, must be undergone, or the undertaking for ever abandoned."—BACON.

"Nearly all the inventions which we now hear of no more were monstrously ingenious, whilst the inventions which are actually in use are those which appear to have got rid of all the ingenuity, and to have retained one or two plain, simple, common-sense elements."—J. SCOTT RUSSELL.

PREFACE.

In sending forth the First Volume of our New Series we are disposed to address to our readers a few familiar words, which we trust will be received by them with favour.

In the first place, we have to acknowledge the support which many New Subscribers have accorded to us since January last; and this we do with the more satisfaction because it has been rendered without solicitation on our part. We have not, we confess, either the time or the disposition to make those appeals to the public—by way of ingenious advertisements and otherwise—which contribute so greatly to the success of many publications; and, we doubt not, we suffer, to a certain extent, for our inactivity in this respect. But we are happy to say that, notwithstanding this drawback, the number of our subscribers and friends has steadily and largely increased. Nor is our constituency (if we may so speak) extending itself among mechanical men only: we find that the officers of Her Majesty's Navy and Army are continually swelling the list of our supporters. This fact affords us much pleasure, both on account of the natural regard which we all feel for the classes to whose skill and gallantry our national honour is committed, and on account of the importance which must of necessity be attached to the acquisition of scientific knowledge by our naval and military men. We earnestly hope to find our acquaintance with them still increasing; and to this end we make bold to request our present naval and military subscribers and readers to aid in extending our circulation among their professional brethren.

If we had any desire whatever to mention with complacency our own labours during the last six months, we might refer to our efforts in connection with the Armstrong Gun, the ships of the Navy, the Coinage, the Mediterranean Telegraph, the Patent Laws, and several other topics which we have discussed elaborately, and with some visible, and more invisible, results. But this subject we leave to others. We could wish, however, that our readers should discriminate between the management of this Magazine and that of some other journals which have lately started into existence, ostensibly in the interests of popular science, and which are maintained (where they have not already ceased to appear) by a system of piracy that is most disgraceful. The staple literary material of such publications as those to which we here refer is obtained by sheer plunder, and by that alone. Articles from our own Magazine, and even the contents of expensive volumes, are reproduced in them without the least acknowledgment of the sources whence they are derived. It is in this way that such periodicals are, in some instances, forced into a tolerably wide circulation—only, of course, to disappear when their character becomes understood. Now, we may fairly and confidently say that our columns afford no example of this kind of deception or fraud. All that we publish either proceeds directly from the pens of ourselves and our colleagues, or else has its origin plainly authenticated. Nor do we, as Editors, aim at anything like mere literary display. What we value, and what we believe others value, are facts, and these it is our constant endeavour to provide. The extent to which many of our articles are reprinted in the leading journals of this and other countries, and the influence which those articles are openly admitted to exert, assure us that we are far from unsuccessful in our efforts.

In conclusion we will only say that, while conscious of many defects which have marked our course during the issue of the present volume, we nevertheless hope we have done enough to ensure the permanent support of that large and cultivated body whom it is our privilege to address from week to week.

THE EDITORS.

June, 1859.

THE
MECHANICS' MAGAZINE.
LONDON, FRIDAY, DECEMBER 31, 1858.

EDITORIAL ADDRESS.

MORE than thirty-five years have passed since the First Number of the MECHANICS' MAGAZINE appeared, with its memoir of JAMES WATT—its diagram of two solemn bricklayers in a diving-bell—its portrait of a winged enthusiast flying in the air, (downwards, of course)—its cure for a cold—its Tantalus's cup, with a despairing Tantalus in it—and its poetical Address to a Blacksmith on his birthday! Very small and very crude was that first threepenny sheet, with its sixteen pages only, poetry included. But small and crude as it was, it proved to be the beginning of a publication which has unquestionably exerted great influences upon modern science—has formed the model for scientific journalists throughout the world—and has now taken a novel form, only that it may give a fuller development to the energy which belongs to it. Nor was that first number the precursor of great literary influences alone. For in its pages Mr. ROBERTSON, its founder and editor, took the lead in the establishment of the London Mechanics' Institution, and virtually of all those kindred institutions which now abound in the land.

We, the present editors of the Magazine, refer unhesitatingly to these early triumphs, since we had, of course, no personal participation in them. It was our pleasure to succeed to its control after it had grown in stature and come into favour. Nay, favour is a word that very imperfectly expresses the regard—we may even say the affection—which many hundreds of readers feel for the MECHANICS' MAGAZINE. To some few it is like an adopted child, to many more it is as an old and favourite friend; and we should be unworthy of the position we hold were we insensible to the interest which such persons feel in it. We are, however, fully sensible of it; and it is upon the solid basis of their esteem that we build our expectations of the future.

All the friends of the Magazine were of late, however, agreed in believing that the time had come when a change in its form and size was eminently desirable. Its page was too contracted for the engravings of many modern machines, and its literary department afforded insufficient scope for all the demands of modern science. A want of a weekly scientific paper, handy in size, copious in information, and sound and reliable in its teachings was felt; and we were looked to as the most proper persons to supply the want. We have undertaken the task cheerfully, and the mere preliminary announcement of our intention in the matter has brought us so much support that our success is already assured. We hope and believe that this first number of our New Series will confirm our present friends in their friendship for us, and bring us many new ones.

It will be observed that to our title of MECHANICS' MAGAZINE, which is not, in the present day, a perfectly definite designation, we have appended a sub-title, viz.: "Journal of Engineering, Agricultural Machinery, Manufactures and Shipbuilding." This has been done with a clear and settled purpose, which, though it may not be evident to some readers, we need not here mention. Some gentlemen have, however, predicted our want of success because of the number of the branches of practical science which we thus embrace. But very close observation has shown us that this prediction is based upon a fallacy. It is a very great mistake to suppose that intelligent men wish to confine their scientific reading exclusively to subjects connected immediately with their own vocations. We need not go back to the days of WATT and ARKWRIGHT to prove this. Every day men are now studying and inventing things which lie more or less apart from their personal pursuits. The best steam-plough yet produced, which is described on another page of this number, was invented by an engineer and farmer together. The late electrician of the Atlantic Telegraph Company was a doctor in Brighton. The most effective cannon which the military man has yet had given him, is the invention of Mr. W. G. ARMSTRONG, an hydraulic engineer of Newcastle. The standard work on Naval Gunnery, was written by a general. One of the latest schemes for draining London was propounded by a Judge. A novel mode of ship-construction is about to be produced by an eminent constructor of marine steam-engines. It is undoubtedly true that professional men require to be informed of what is new in their own professions; but it is not less true that, for the most part, they desire also to be advised of what is being done in the professions of others. And it is well for the world that they do; for many of the greatest improvements made in the arts and manufactures are produced by men who step aside from their own occupations to make them. We have no apprehensions on this subject. On the contrary, we know that the engineer will value us the more for our agricultural machinery; the agricultural machinist for our manufactures; the manufacturer for our ship-building; and men of science generally for all of these.

We have a word to add upon the management of the Magazine in its new form. We intend to fully maintain our independence, and with it, we trust, our consistency. For some cause or other, the scientific journals which do this are exceedingly scarce. We look to most of them in vain for a predominant unity of thought and purpose, from which alone the reader can derive any real culture—any abiding advantage. Such journals appear to be edited by a staff of writers who are void of nearly all faculties but that of mutual contradiction. The laws of science are repealed, perverted, restored, and abolished at will by them. We find the Atlantic Cable crack at the bottom of the sea one week because of the intense cold, and melt there the next because of the boiling heat. This week a plough answers admirably on account of its lightness—next week it is superior to all others on account of its great weight. In one number a ship steams at 15 knots because she is down at the head—in the next she steams at the same rate because she is by the stern. Now all this—or rather, all of which this is a disguised representation—is exceedingly absurd and injurious. The laws of science are fixed, and those who undertake to expound them should not prevaricate. We know that perfection is not possible of attainment in dealing with the varied facts to which experience daily gives rise; but we shall, on our own parts, feel it due to the public to prefer even silence to false and doubtful comment.

We have another word to add to correspondents. From these we shall be most happy to receive whatever they may please to send us, but we shall exercise our right of rejection more severely than heretofore. It unfortunately happens that some of our best men write very little, and some of our worst very much. This is an evil to be deplored; but our duty, as editors, is plain. We cannot sacrifice the patience of thousands of readers for the sake of gratifying one frivolous or mistaken writer. On the other hand, for really useful communications we shall at all times tender our best thanks.

We have introduced several improvements in the details of the Magazine, chiefly in connection with the classification of the abridged specifications of Patents, &c., which will be severally explained in their respective places. The price of the Magazine is raised from 3d. to 4d., but we do not for a moment anticipate that the slight increase will, by any reader, be deemed a serious drawback, or an unreasonable accompaniment of our enlarged efforts and expenditure. In conclusion, we wish our readers a Happy New Year, and request them to contribute to the happiness of ours by aiding us in circulating this Magazine as widely as possible, that, as it flourished before many of them were born, so it may still flourish for the public benefit till they and we are no more.

STEAM BOILER CONSTRUCTION.

BACON hoped for an organ which should enable all men to construct scientific truths as a pair of compasses enables all men to construct circles. But, great as the progress of science has of late been, we see no promise of any such organ. The chief part of those scientific truths which are essential to the advancement of the useful arts, have to be produced by that cumbrous and clumsy instrument—experiment.

"Science moves, but slowly, slowly, creeping on from point to point."

And yet we have but little cause for complaint of this instrument. How much has it not done for us even during the present century, in bringing steam, electricity, and a thousand natural products under our control, and subservient to our uses! Steam-ships, railroads, iron bridges, and crystal palaces, are but a few of the results attained by aid of it. And it is daily giving us new and valuable advantages.

No man has laboured more usefully, or more incessantly, on experimental subjects than Mr. FAIRBAIRN, and considering the awful destruction of life which boiler explosions have occasioned, he never, perhaps, laboured to better purpose than when he made his late experiments on the resistance of tubes to collapse. The complete results of these experiments, in so far as they were contributed to the Royal Society during the present year, are now, by the courtesy of the author, before us. On another page we have given, in his own language, the practical application of these results to the construction of boilers. The article needs no commendation to practical men. The experiments were instituted for the purpose of improving our knowledge respecting the forms of construction best calculated to sustain those high pressures of steam which have lately been rendered necessary by the general desire to economise fuel, and to extend the expansive principle; the resort to these pressures having been followed by numerous and aggravated explosions. The worst of these have resulted from the collapsing of the *internal flues*, which have been largely adopted, and the number of which late experiments at Sheerness Dockyard will tend to increase. It has been the habit of engineers to form these flues of boiler plate, riveted with simple lap-joints into cylinders; and these were considered to be of equal strength—when of the same material, diameter, and thickness—whatever their lengths. It is perfectly reasonable to suppose this, if the cylinders be unsupported at their ends; but, it is equally reasonable to suppose that where their lengths are short and variable, and their extremities held by rigid supports, their strengths would vary materially. In some experimental tests to prove the efficiency of some certain boilers, Mr. FAIRBAIRN had some misgivings as to the strength of the internal flues to resist a force tending to collapse them. In these experiments it was found that flues 35 feet long were distended with considerable less force than others of similar con-

Digitized by Google

struction 25 feet long. This anomalous result led to further inquiry, and this being far from satisfactory, the late experiments were fortunately undertaken.

Mr. FAIRBAIRN has not only performed the experiments with his accustomed care and judgment, but has also deduced from them practical improvements of very great importance. His results, though by no means singular, or adverse to what might have been anticipated by a scientific mind, will render a change in the construction of boiler flues inevitable. They prove that the resistance to collapse of such tubes from a uniform external pressure, varies inversely as their lengths in all ordinary cases—say, for lengths not exceeding fifteen diameters. They further show that in boilers of ordinary construction, the external shell is three or four times more capable of resisting the forces which tend to burst it than the flues are to resist the forces which tend to collapse them. This amply explains the causes of the many disastrous accidents that have been occasioned by the collapse of internal flues. The maximum strength of the structure, as a whole, is, of course, that of its weakest part only, and consequently the excessive strength of the outer case is valueless. The strength of the flues may, however, it is found, be increased nearly threefold, by the mere addition of a couple of strong angle-iron ribs to each of them. By further forming such flues with double-riveted *butt-joints*, and longitudinal covering plates over the joints, their circular form may be preserved, and another great source of weakness thus got rid of. These improvements, though extremely simple, are of immense value, and their general adoption will add much to our security in the use of steam boilers.

NAVAL ARCHITECTURE.

OUR ship-building readers must not be disappointed when they observe how small a portion of our present number is addressed primarily to themselves. In the article on "Naval Warfare with Steam," they will find a few questions of special interest discussed; but on the whole they may with fairness be disposed to complain of the meagreness of the information afforded them this week on subjects of a professional nature. Without entering into the causes of the deficiency, we may state that they are of a transient character, and the defect will not again exist. We have already completed arrangements for a series of articles upon the theory and practice of ship-building, and are also making provision for frequent papers on the actual works in progress in the various Dockyards of the kingdom.

To the contemplated articles on the theory and practice of ship-building—in which we include the Laying Off of Ships—we attach very great importance. We shall mis-represent no one when we say that a great and pressing want of comprehensive treatises upon these subjects unquestionably exists. In the Royal Dockyards there are hundreds of shipwright apprentices in training, and in the private yards thousands. And beside these, there are many thousands of other young men, who have completed their apprenticeship, but who are, nevertheless, earnestly desirous of gaining a sound knowledge of their profession. But to all these—young men "serving their time," and young men "out of their time"—how little sound and useful professional literature is accessible! Now, we propose to supply precisely what they need. Apart from such information as we may from time to time furnish respecting the mechanical building, or putting together of the parts of the ship, we intend publishing two distinct classes of papers, in which we hope to combine sound science with good practical instruction.

The first of these will treat of all that relates to the calculations which require to be made by a scientific constructor of ships; and our aim will be to give numerous and useful illustrations of the several problems which he has to solve. For example, instead of confining our investigations to one particular water-line—as is always the case in books, but hardly ever the case in practice—we shall give a ship several water-lines, and discover what qualities she possesses when immersed to each of them. It is not possible to treat the whole, or even many, of these problems without assuming some knowledge of the higher mathematics on the part of the student. But we shall carefully demonstrate them in the most elementary manner possible, and afterwards give the rules deduced from the demonstrations; so that even those whose mathematical attainments are but slight, may still be able to solve the problems practically—in the same manner as questions in Practical Geometry are solved without a knowledge of Euclid's Elements. We would, nevertheless, earnestly recommend those of our young readers who aspire to become naval architects, to extend their mathematical knowledge as fully as possible, by which means alone they can attain to a proper understanding, and a true enjoyment of their art. There are a few invaluable works on Naval Architecture, which it is next to impossible for the general reader to obtain; and upon these we shall fall back as occasion may require, in order that we may omit nothing of importance to the Naval Architect from our papers. We shall also give several entirely new forms for conducting the necessary calculations, together with the solutions of many questions which arise in the investigation of a ship's qualities, and of which solutions have never yet been published for the guidance of those who have to make the calculations, but who are unable to solve the problems on which they depend.

The aim of our second class of papers—on Laying Off—will be no less ambitious than that of our first class. We propose to adopt an entirely new and, we believe, a highly-improved method of teaching this somewhat difficult and repulsive subject. While the only treatises that have hitherto taught Laying Off are of a purely technical character, and dissociated from those geometrical principles upon which the draughtsman's art is based, we shall make those principles our starting points, and proceed from them to the actual operations of the mould-loft floor. This is unquestionably the only truly scientific method of teaching Laying Off, and we are persuaded that it will tend, more than any existing system, to thoroughly instruct the student who gives his attention to the subject.

We hope to commence the publication of one, at least, of our series of articles on Naval Architecture next week, and to continue the same, with little or no intermission, until they are completed.

THE NEW FOREIGN OFFICES.

THERE was a time in England's history when the ministers made laws, and either trusted to, or cared not for, the approval of the community. But of late years, the wisest proposition gets no sanction or open patronage from those in office until it has been well agitated and ventilated out of doors. The law is then granted as a graceful concession to the wishes of the majority; and, should it prove less operative for good than was expected, the minister stands beyond the reach of censure, and the country patiently submits to its operations as the parent submits to a wayward child.

Some such operation is now going on in regard to the project for the new Foreign Offices. No *official* announcement that a selection of the plans of any one architect has been arrived at has yet been made, but, while there may exist a disposition to confer the honour upon some especial one of the competitors, the enlightened portion of the public are first to be probed to see how far it would stand so flagrant a breach of the proprieties. If the pseudo-announcement which fairly stunned the profession, properly so called, had been quietly accepted as a fact, then the official order would, perhaps, have followed as a matter of course; but no such thing up to the present moment has taken place.

We are aware that in taking this view of the affair we go beyond the inferences drawn from the announcement by many able and far-seeing men, who will not accept even so much as would imply that there ever existed one tittle of authority for the announcement at all. With these gentlemen the announcement assumes simply the nature of a "canard." They say, that professional capital is to be made out of it, whether the affair is true or false; and, indeed, they go farther than this, and affect to see in the apparently hostile letters in the *Times* and other journals, the artful jobber firing his pellets to provoke a war of words which cannot do other than render popular the individual who is the cause of it. We should not call attention to this phase of the case, did we not feel that there is much to justify such a conclusion. We have no proof, however, that such is the fact; but its existence would not surprise us after what has occurred upon similar occasions of public competition.

Under any circumstances it is now high time that Lord JOHN MANNERS should take some notice of the rumour. Let that nobleman confirm it if it be true; let him deny it if it be false. If, however, he should be made to continue silent by the requirements of official dignity, what could be easier than for some one of the competitors to ask the question of his lordship? Surely they are most interested in the decision, and it would need no very great space in their note to be devoted to apologies for so suggestive a course.

Whatever may be the result, the public are indebted to the "announcement" for awakening a large amount of dormant feeling for Art amongst a class of intellectual men which is becoming every day more and more conversant with the elegancies and requirements of an enlightened society. These men possess a cool judgment, allied to an independent and logical mode of thought. They are, moreover, lovers of a rational and vigorous progress, and from them we may hope that at no distant time we may be able to "announce" the advent of a movement which will at once and for ever place the whole phalanx of copyists and pattern manufacturers in the position they naturally and necessarily occupy in every profession, excepting the great and noble one of architecture. Then may arise some great genius, modestly impressed with the importance of his mission, and endowed with power to advance the art upon which ages and nations almost wholly rest the glory and perpetuation of their worldly fame.

In a commercial point of view, we unfortunately at this moment permit our money to be squandered on the whim or fancy of any well-connected mortal, who may be in his dotage, and never have the opportunity of seeing the coming generation look with sovereign contempt upon the works held *in terrorem* over suffering "Taste." The system of filching from old German and Flanders examples may be all very well for a little while, but the constant borrowers of ideas, like the fitful customers of

Digitized by Google

the usurer, can never permanently benefit themselves or their immediate friends.

All honour to the inventive genius who shall arise through the present debasing atmosphere of false sentiment, and redeem once and for ever our really liberal country from the burden of mediocrity under which it now labours! And all honour to those men who, though not thus gifted, may hail the advent of such a leader, and secure for themselves a position by falling into the ranks of their general as befits true and faithful soldiers of Art!

THE SMITHFIELD CLUB SHOW.

EVERY year adds to the importance of our great agricultural gatherings, not the least of which are the exhibitions of cattle and implements at the Baker-street Bazaar, which are looked forward to by some hundred thousand persons with almost the same interest as the good old Christmas pantomime, without which London at this season would no longer be itself. Notwithstanding the additions which have from time to time been made to the area devoted to the Christmas show at the Baker-street bazaar, it has grown less and less compared with the number and variety of things exhibited, until upon the last occasion the "standings" only measured two feet nine inches in width instead of ten feet, which was their extent about eight years ago. This diminution of space, for which, by the way, the same charge is made as formerly, has arisen from the increased number of applications made year by year; the principle adopted being that of dividing the area into as many standings as are applied for, so that if the same building be used, a few years will suffice to reduce each standing to as many inches as it formerly reckoned feet. This has necessarily greatly increased the cost of exhibiting implements, and no doubt presses severely upon small makers, a few of whom, we noticed, had contented themselves with just room enough for a man to stand upright in, and whose occupation was simply that of distributing catalogues or hand-bills, necessarily borrowing from his next door neighbours the elbow room required in the discharge of his duties, or when he desired to put his hands in his pockets. Those exhibitors, on the other hand, to whom a few pounds are no object monopolise as many as ten, twenty, thirty, or in one case as many as forty standings, and were consequently enabled to make a considerable display. All this will doubtless be shortly remedied, as it is scarcely possible that the premises hitherto used for the purposes of the show, can very much longer suffice, considering the increased accommodation now so imperatively called for. We understand that so great were the inconveniences acknowledged to be on the last occasion, for want of space, that a committee has actually been appointed to inquire into the possibility of finding more suitable quarters. The Crystal Palace has not been overlooked by those who have given any thought to the subject, but its distance from town is a very serious objection, especially as in order to retain the popularity of the Christmas show, it must be open in the evening as well as in the day time. Another plan has been suggested of holding the shows in some accessible spot under some temporary erection which could be contracted for in the same way as the canvas sheds adopted by the Royal Agricultural Society; but to this, there is some considerable objection on account of the season of the year, which requires the cattle to be well protected from the weather. Perhaps this objection might be overcome by artificially heating the cattle department; a few thousand feet of iron hot-water piping accomplishes wonders in the way of warming long ranges of buildings, or those which are separated by considerable distances. We have no doubt that many of our hot-water apparatus makers would readily undertake to maintain a uniform temperature in a length of canvas-covered and timber-sided shedding, amply sufficient to hold all the bullocks, sheep, and pigs which the breeders and rearers of England could desire should be brought together. The real difficulty is, doubtless, to find the ground space, but this it is possible the committee referred to may succeed in doing, if they heartily set to work, as we trust they may do. Before concluding these introductory remarks, we should, perhaps, offer some apology for the late appearance of our notice of the Smithfield Club Show, which is simply this: That, until our present number (the first of the enlarged series) and only with difficulty even now, has it been possible to afford it space in our columns. A careful record of the great improvements in agricultural machinery continually being made, and yet to be made, can, however, be hardly better inaugurated than by a short, yet systematic account of what we noticed at the late show; and this consideration, added to the fact that no detail statement has as yet been published, has determined us, even thus late, to draw the attention of our readers to those matters which most interested us in our ramble through the implement department. In our notices of machines or implements exhibited, it must be carefully borne in mind that we profess to do little more than refer to such as were exhibited for the first time at any show of implements, or at any rate which had not before been shown at the Smithfield Club Meetings. This will, of course, account for the absence of mention of a vast number of well known names as exhibitors, and as well known machines and implements of those whose names do appear in reference to agricultural machinery recently introduced. We notice the stands in the order in which we examined them.

T. Scott, of Drummond-street, Euston-square, exhibited a new machine—a grass-seed separator, for extracting the seeds of couch, twitch, spear, or hair grass, and other impurities from perennial, or Italian rye-grass, &c., as also a carrot-seed bearding and dressing machine for cleansing the seed of the beard or awn, and rendering it fit for sowing. By a slight modification this machine may be used for milling clover, trefoil, and other similar purposes. It is calculated that 5s. per acre is saved in the cost of seed by the use of this machine. Into the details of this saving we cannot enter, but there is no doubt that great advantage arises from thus preparing seed. These machines are manufactured by Middleton, the well known engineer of Southwark.

Mr. Romaine exhibited a model of his steam cultivator, as intended to be manufactured by Mr. Nash, of Cubitt Town, Isle of Dogs. This machine contains many important improvements over those hitherto constructed for Mr. Romaine. It is in reality a rotary digger, the digging apparatus being a cylinder with spades placed behind the engine. The spades are firmly bolted to the cylinder by three bolts placed triangularly (two of them at the point of greatest strain) and passed through the metal of the cylinder. The cultivator travels slowly over the land, digging a width of eight feet, but has a faster motion, by which, when not digging, it can travel from place to place at about two miles per hour. The cost of the machines will be about £800 each, the working expenses being set down at about 33s. per day, and the quantity of land cultivated about seven acres. The steering apparatus appears well arranged, and the machine is made to turn almost in its own length. So far as we could judge from the model exhibited, Mr. Romaine appears at length to have succeeded in devising the machine so long and earnestly looked for by many, and even by Mr. Fowler, to be forthcoming some day or other, namely, a machine which can work its way into an unprepared field and ont again, having spaded up the soil to any depth required, and that without the spades or forks clogging—the cylinder on which they are fixed preventing any accumulation of earth which would take place were they merely attached to a shaft, instead of to a large cylinder. We hope in a few weeks to give illustrations, and detail description of this interesting implement.

Mr. Unite, of the Edgware-road, exhibited some *gelicw* dressed carriage aprons, which, as far as appearances go, are doubtless preferable to black ones, and which, from the nature of the dressing, are not liable to crack or scale. The specimens shown were exceedingly pliable, exhibiting none of that harshness which renders many aprons as stubborn as sheets of metal laid across the knees, and almost as cold and comfortless.

Messrs. Hornsby and Sons, of Grantham, exhibited their newly-patented plough, manufactured wholly of wrought-iron, with the exception of the slide, name-plate, and wheels. In this plough, the share and turnfurrow, or breast, are attached to the slide or sole plate, instead of to the frames, as usual; thus the beam, handles, and frame, are solid pieces of wrought-iron work, obtaining the greatest possible lightness, with great strength and durability—doing away with the heavy cast-iron frame in ordinary use, and, at the same time, giving to the plough a light, simple, and pleasing appearance. The shares are attached to lever necks of wrought-iron. They are so constructed that no dirt can possibly work into the joint to interfere with its free action, which is capable of universal movement; and being spherical, it is the firmest, and most easily adjusted arrangement that can be introduced for giving it more or less pitch; as also for directing the point of the share more or less to land. The spherical bearing is fixed close to the share, so that giving it more or less pitch or land movement does not raise it above or below the front of the breast. The coulter fastenings are made wholly of wrought-iron; the coulter is very easily adjusted for cutting in-land or furrow, and at a greater or less inclination. Skim coulters, with wrought-iron stems and steel miniature mould boards are attached to these ploughs, by a wrought-iron clip, and also drag-chains when desired. The wheel stems are fastened to slides passing through holes in the beam, and a piece is welded on the underside of the beam, through which they also pass, giving them a firm wide bearing. By this arrangement the land wheel can be expanded or contracted, dispensing with the slide axle at the bottom, and causing the wheels to run nearly opposite to each other. The wheels are constructed so that no soil can adhere to, or be carried round by them, as is the case with the wheels of most ordinary ploughs, the rims being bevelled on the inside.

Messrs. Garrett and Sons exhibited, in addition to their usual collection, a horse hoe with newly arranged steering and elevating apparatus, both operations being effected by means of a single handle. The axletree is made moveable at both ends; thus the width or spread between the wheels can be increased or diminished according to the method of planting, so that the wheels always travel between the rows. Each hoe works on an independent lever, by which means they either rise or fall according to the irregularities of the surface of the land. The steerage, which is in itself very simple, consists of a quadrant gearing into a rack, and affords a ready means of keeping the hoes between the rows of corn or vegetable crops, doing every execution to the weeds without the slightest injury to the crop. The hoes may be varied in distance, to suit all crops, at any given width that may be required. The cutting blades, of different sizes, are made of steel, and attached by screw bolts and nuts to the stalks, which are keyed into the levers, and when worn may readily be replaced by any farm labourer. We should not omit to notice an improvement in what are called the "continental two-horse" thrashing machines, which are known as one-horse machines in this country. The improvement consists in arranging the vertical bevel wheel within the circumference of the horizontal one, which enables the machine to be packed in a square case, thus saving freight.

Whitmore and Co. exhibited several crushing and other mills; the most noteworthy, as being the most recent, were the small mills for splitting beans, peas, Indian corn, &c., capable of splitting four bushels per hour, the cost of each mill being under £3.

Burgess and Key exhibited a new grass mower

Digitized by Google

(Allen's American patent). This machine has been thoroughly tested during the last season, and found to answer perfectly—one machine having cut, on the farm of Mr. C. Hall, of Havering, Romford, Essex, 83 acres; and afterwards, on the farm of Mr. Tabrum, Bovis Hall, Brentwood. 100 acres of grass and 20 acres of clover. The work was done better and lower than by the scythe, and at the rate of one acre per hour. They also exhibited a new potatoe-digging plough (Owen's patent), which weighs only eighty-five pounds, is light of draught, and simple in its construction. One man, it is said, with a pair of small horses, will easily dig potatoes as fast as twenty persons can pick them up. The potatoes are turned out and distributed on the ground so that scarcely one per cent are left covered. It works well on hill sides, on rough or stony land, and on all soils. This implement can be used as a cultivator in the early part of the season, it being admirably adapted to run between rows of potatoes, turnips, &c., to eradicate the weeds and lighten the soil. The next thing we should notice is a "post-hole" augur, also invented by Mr. Owen, which combines the advantages of the shovel, spade, and post-spoon, producing a round smooth hole. The augurs are made of convenient size and length for boring holes in the ground suited to any sized post. They lift the dirt from the hole without the use of a spade or spoon; and as no more is removed than is necessary, the work is much more rapidly performed than usual. Messrs. Burgess and Key also exhibited a number of churns similar to the one which gained the prize at Chester, and considerable attention was paid to the celebrated reaper which occupied a prominent place in the exhibition. We understand that the Prince Consort, owing to his having one of the reapers on his farm at Windsor, had a prolonged interview with Mr. Burgess on the merits and capabilities of the machine, which appeared to have entirely realized the Prince's expectations.

Ruston, Proctor, and Co. exhibited one of their portable grinding mills with wooden framing, which lessens its cost about £7. These mills will grind six to ten bushels of meal an hour, according to the fineness of the work. The top stone, being the runner, is driven by an upright shaft, which receives its motion from a pair of bevel wheels at bottom, one of which, to prevent noise, is geared with wood. This firm also exhibited an improved circular sawing bench, which possesses many advantages over those generally in use. It consists of a circular saw fixed in a cast-iron planed table, and is mounted on cross oak soles; turned wrought-iron rollers are fitted to each end of the table, and three sizes of augers to the spindles for boring. It is driven by a double-flanged pulley, and the brasses carrying the spindle are applied in an extra strong manner, and are adjustable by set screws and lock nuts. The fence is an arrangement of screws and pinions, very correct and certain in its action. It has the parallel, transverse, and feather-edged or diagonal cutting motions; may be adjusted to suit any sized saw, and is set to a gauge, marked on the table in eighths of an inch. We must next notice the excellent portable engines of this firm, one of which was exhibited. The most noticeable points of these engines are that the saddle for the fly wheel shaft completely straddles the boiler, thus guarding against any derangement from unequal expansion; and the engine is also fitted with an improved throttle valve, which by means of a governor regulates its motion whether lightly or heavily loaded. The tubes are arranged in vertical rows, leaving a clear half-inch space between them from top to bottom, there being an inch space between the outsides of each pair of tubes. The slide valves are case-hardened. The capability of these engines is considerable, as 8½ square inches of piston area are allowed for each horse power, the pressure of steam being 45 lb. per square inch. We believe one of these engines tried at Chester, with the eight horse brake, made 130 revolutions per minute, with the steam at 24lbs. only. The force pump is fixed vertically at the back end of the boiler, thus avoiding a long eccentric working rod, and an equally long return pipe, both of which are necessary when the pump is inclined in the usual way. A combined thrashing machine was exhibited by this firm at the Gloucester Mews in the neighbourhood of the show. Messrs. Ruston, Proctor, and Co. are the makers of Smith's ploughing apparatus, which was at work during the show at Flemish Farm, near Windsor.

Wallis and Haslam, of Basingstoke, exhibited their self-adjusting spherical bearings, which appear admirably suited to agricultural machinery, the accurate setting of which cannot, from want of good foundations or other causes, be generally depended upon. These bearings are well adapted for shafts or spindles which run at a high speed, or are at all liable to heat, as they adjust themselves to the slightest variation in the line of direction of the shaft, while, at the same time, they are perfectly steady in work, and, as they wear equally throughout their whole length, will no doubt last much longer than the ordinary bearings. The spherical bearings are composed of four parts, viz.: the seat or block, the upper and lower brasses, and the cap. The seat or block and the cap are turned, so that when put together, their interior surfaces form a spherical cavity, with a portion removed on each side of the block, forming openings through which the shaft or spindle passes out, surrounded by the brasses in which it revolves; and the upper and lower brasses, after being bored in the usual manner, are turned externally to the form of a sphere of the same diameter as the cavity in the block, so that on their being placed in the cavity, and the cap adjusted over them in its place, they form a universal joint, which will turn freely in any direction within certain limits. On the under side of the lower brass is cast a nipple, which descends into a socket bored in the bottom of the block to receive it. This socket is considerably larger than the nipple, and will therefore allow sufficient motion for the brasses to adjust themselves to the position of the shaft, while, at the same time, it prevents their rotating along with it, which they might otherwise be liable to do.

We are sorry that our space precludes the possibility of our adding to the above remarks, as certainly not one-third of the matters deserving notice has been as yet touched. We trust, however, to complete our survey of the show next week, when we hope all exhibitors will find their respective claims to notice duly acknowledged. The names of those whose productions we have as yet spoken of appear in the order in which our notes were made, it not being possible, in the crowded state of the building to take any regular course in examining the several stands.

H.M. SCREW STEAM SLOOP "ICARUS."

The trial of the *Icarus*, Screw Steam Sloop, took place down the river on Tuesday, the 21st December last. She left Woolwich Dockyard at 10.25 a.m. and reached Gravesend at 12.12 with a strong tide against her, after which she made several runs with and against tide, at the measured mile, Lower Hope, under the superintendence of the Woolwich authorities and Messrs. Rennie, the constructors of her engines.

The average speed thus obtained was 10¼ knots. The engines indicated above 600 horse power, making from 90 to 94 revolutions per minute. There was no heating in any part, and the trial was highly satisfactory to all concerned.

The dimensions of the *Icarus* are as follows:

	ft.	in.
Length between perpendiculars	151	0
Beam extreme	29	1
Depth	15	10

Tonnage, O. M. ..... 577 $\frac{3\cdot0}{9\cdot4}$

The engines are 150 horse-power collectively, by George Rennie and Sons, on their patent single trunk principle.

We are informed that Messrs. Rennie were little more than four months in constructing these engines, and the engines were tried one month after the vessel was handed over to them by the authorities.

ON IMPROVED MODES OF CONSTRUCTING THE FLUES OF STEAM BOILERS.

By W. FAIRBAIRN, Esq., C.E., F.R.S., F.G.S., &c.

THROUGHOUT the whole of the experiments on the resistance of tubes to collapse, lately undertaken by me at the joint request of the Royal Society and the British Association for the Advancement of Science, it has been proved that the resistance to collapse from a uniform external pressure, in cylindrical tubes, varies in the inverse ratio of the lengths. This law has been tested to lengths not exceeding fifteen diameters of the tube; but the point at which it ceases to hold true is as yet undetermined, and could only be ascertained by a new and laborious series of experiments on tubes of considerably greater length, in which the strength of the material modifies the above law of resistance to collapse. Such experiments are, doubtless, very desirable; but the vessels necessary for the purpose would be most expensive, and the results already obtained appear to supply all the data necessary for calculating the strengths and proportioning the material in all ordinary cases.

If we take a boiler of the ordinary construction, 30 feet long and 7 feet in diameter, with one or more flues 3 feet or 3 feet 6 inches in diameter, we find that the cylindrical external shell is from three to four times stronger in its powers of resistance to the force tending to burst it, than the flues are to resist the same force tending to collapse them. This being the case in boilers of ordinary construction, it is not surprising that so many fatal accidents should have occurred from the collapse of the internal flues, followed immediately by the explosion and rupture of the outer shell. To remedy such evils, and to place the security of vessels so important to the community upon a more certain basis, it is essential that every part should be of *uniform strength* to resist the forces brought to bear upon it. The equalisation of the powers of resistance is the more important, as the increased strength of the outer shell is absolutely of no value, so long as the internal flues remain, as at present, liable to be destroyed by collapse, at a pressure of only one-third of that required to burst the envelope which surrounds them.

The following table, deduced from my own experiments, exhibits the safe working pressure, and the bursting pressure of boilers of different diameters, calculated for an external shell of a thickness of 3·8ths of an inch.

Diameter of Boiler.	Working pressure.	Bursting pressure.
ft. in.	lbs.	lbs.
3 0	118	708½
3 6	101	607
4 0	88½	531
4 6	78½	472
5 0	70½	425
5 6	64½	386½
6 0	59	354
6 6	54½	326½
7 0	50½	303½
7 6	47	283½
8 0	44	265½
8 6	41½	250

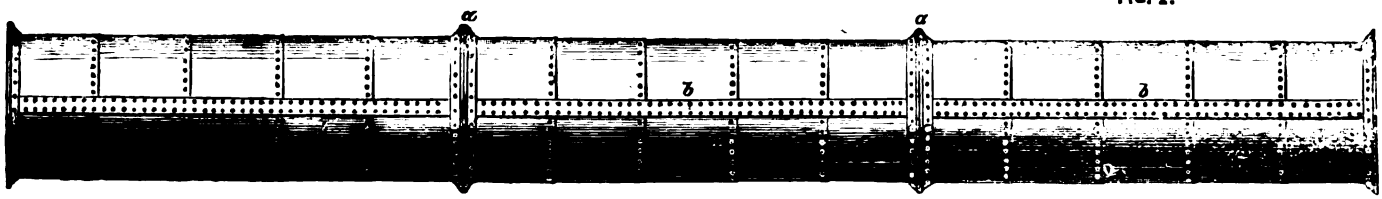
Taking from the above table the strength of a boiler 7 feet in diameter, we find its bursting pressure to be 303 lbs. per square inch. For such a boiler the flues would be ordinarily 3 feet in diameter, and of the same thickness of plates as the shell; and by the formula, log P = 1·5265 + 2·19 log 100*k*—log (L.D.), we obtain for their collapsing pressure 87 lbs. per square inch. As, however, the formula does not apply with strictness to tubes of such length, the actual collapsing pressure will be somewhat greater than this. The immense excess of strength in the outer shell is, however, sufficiently apparent; the extra thickness of boiler plate which causes it being so much material thrown away, adding nothing to the strength whilst the flues remain in so dangerously weak a condition.

To meet this disparity of strength, the experiments indicate the necessity of *shorter* flues, and one of them shows how this may be obtained, practically and efficiently, without interfering

Digitized by Google

MR. FAIRBAIRN'S IMPROVED BOILER FLUES.

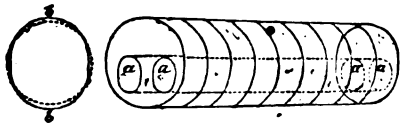
FIG. 1.



With the present construction of boilers. A tube was divided into three parts by two rigid rings soldered upon its exterior, and its powers of resistance were thus increased in the ratio of three to one; *virtually*, the length was reduced in this ratio, and the strength was *actually* increased from 43 to 140 lbs per square inch.

It is proposed to apply a similar construction to the flues of boilers, to equalise their powers of resistance with those of the outer shell, on the supposition that the law of decrease of strength holds true, within no great limits of error, to tubes of much greater length than in the preceding experiments. That this conclusion is not empirical, will be seen by the following experiments upon boilers of full size, where it will be observed that the flues were distorted with one-third the pressure required to rupture the external shell.

These boilers were made for the North-Eastern Division of the London and North-Western Railway Company, and were respectively of 35 and 25 feet in length. They were 7 feet in diameter,

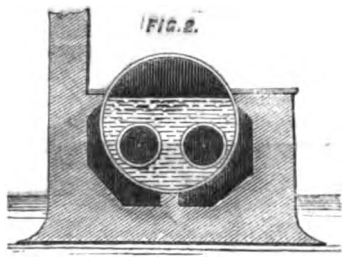


and composed of plates 3-8ths of an inch thick. Each boiler had two cylindrical flues 3 feet 6 inches in diameter, and of the same thickness of plates as the outer shell. They were fixed in the position shown in the annexed diagram, and were intended to resist an ordinary working pressure of only 40 lbs. upon the square inch. In submitting them to the usual test of double pressure, the flues of the first or longest boiler gave way with 97 lbs. upon the square inch; and those of the shorter boiler required 127 lbs. to effect the same distortion. With these large tubes a complete collapse was not accomplished, but the circular form, indicated by the dotted line, was *distorted*, and the flue became elliptical, as shown at *b*, *b*.

The weakness of the flues in the above experiments is so evident as to need no comment. To remedy it, it has been already stated, we need only resort to a construction so simple, and yet so effective, as to meet at a small expense all the requirements of the case. In an ordinary boiler flue, 30 feet long and 2 feet 9 inches in diameter, with simple lap-joints, as hitherto invariably constructed, it will only be necessary to introduce two strong, rigid, angle-iron ribs, as exhibited in fig. 1, at *a*, *a*. This arrangement will increase the strength three-fold, and will not only remove all doubts as to the strength of these flues, by bringing them within the limits to which the formula applies with strictness, but will give to flues 30 feet long, a strength equivalent to that of flues only 10 feet long, and make them uniform in their powers of resistance with the other parts of the boiler.

The reduction of the strength of flues by the lap-joints has already been stated; the deviation from the true cylindrical form which they cause, lessens, in some cases, seriously the strength of the vessels. Hence it is also proposed that flues required to resist an external pressure should be formed with double-riveted *butt-joints*, with longitudinal covering plates, as shown also at *b*, *b*, *b*, fig. 1. Fig. 2 is a sketch showing the positions

FIG. 2.



of the flues which are found preferable in double-flued boilers. It is believed that these alterations will secure ample safety in these important constructions, and in this trust they are commended to the attention of the engineer and the public generally.

CHANDLER AND OLIVER'S STEAM PLOUGH.

STEAM, which was once so restive as to alarm all our peaceful country gentlemen, is now harnessed quietly enough in the field, and will never cease plodding there until something more potent than it is produced. We have not yet finally decided whether the mighty creature is to stand still and do its work by winding endless ropes, or to march about with a train of ploughs behind it. But that it is henceforth in one way or the other to do our ploughing for us is indubitable. The grave question is now, in what form can we construct and combine our ploughs to best suit its peculiar nature. Mr. Fowler has laboured long, and with much success, in endeavouring to solve this question; but other Richmonds are fast flocking to the field, and, the genius of Progress being no respector of persons, he runs a risk of being beaten by them. We sincerely hope, however, that he may not fail of his due reward for his industry, his skill, his persistence, and his prolonged outlay of capital.

Among the persons who have now for some years been working and spending in furtherance of steam ploughing is Mr. Robert W. Chandler, but lately a modest working engineer, at Bow, and associated with him, Mr. Thomas Oliver, a plain and sensible, but enterprising farmer, at Hatfield, Herts, in the neighbourhood of the Marquis of Salisbury's estates. The two together have from time to time patented several valuable improvements in agricultural apparatus, and have recently added to their inventions an improved form of plough, to be hauled by steam power, which many very experienced agriculturists have extolled, which several implement makers have coveted, in so far as its manufacture is concerned, and which Messrs. Howard and Co., of the Britannia Iron Works, Bedford, are now engaged in producing to order. This improved plough has, undoubtedly, many advantages no where else to be met with. It is a balanced apparatus, like Fowlers, but the ploughs are carried by two independent frames, one on each side of the middle of its length. The balancing is effected by rods or chains extending from the extremities of these frames to arms on a rocking shaft at the middle of the plough, or in any equivalent manner; and the inner ends of the plough frames are connected with racks and pinions or other appliances, whereby they may be raised and lowered—the one rising as the other descends. Thus the inner ploughs, which in Mr. Fowler's arrangement must be situated at some distance from the centre of the machine, in order that they may rise and fall sufficiently to clear the ground, and to enter it as desired, may here be brought close up to the centre. Consequently, Messrs. Chandler and Oliver's machine may be made much shorter, and, therefore, much lighter and cheaper than Mr. Fowler's, and the ploughs may be raised when out of action, and lowered into action with great facility. They also plough up closer to the headlands than the Fowler plough, and beside this afford facilities for reducing or increasing the breadth of the furrow according to the nature of the land under operation.

Fig. 1 of the annexed engravings is a side elevation, and fig. 2 a plan of the Chandler and Oliver plough. A, A is the general frame of the machine, which is made of either iron or wood. This frame is omitted on one side in Fig. 2, that the ploughshares may be shown more clearly. The frame is supported upon wheels B, C, D, but the inventors do not limit themselves to this number, as four or more may, if considered useful, be employed. The wheel B is placed on one side of the frame, and is supported on and works in bearings formed therein. When the plough is at work, the wheel B runs in the furrow that has been last made. The other wheels, C and D, are placed on the opposite side of the frame, and are arranged as shown in the figures near the extremities of the apparatus. The inventors prefer making these wheels of the peculiar shape illustrated in the figures. The wheels C and D work upon short axles, which are screwed or otherwise connected to spindles that are bent in such manner that their ends rise perpendicularly, and carry at their upper parts arms E, E, to which cranks, spindles or rods F, F are attached, which are worked by means of the lever-handles G, G, placed at or near the extremities of the apparatus. Thus, by moving these levers in one or other direction, the apparatus can be steered; that is, the leading wheel can be directed outwards or inwards, as required, either for preserving the regularity of the furrows or guiding the plough into fresh land. The hinder wheel revolves in one position, and is so preserved by placing the pin *c* in the hole *d*, until the plough reaches "land's-end," when the pin is withdrawn and placed in the hole in the spindle of the other wheel, which now becomes the hinder wheel. H, H, are scrapers, which are attached to the arms E, E, and move with them to scrape the mud and stones from the wheels as the plough advances. There is a pin *e* in the axle-spindle to regulate the depth to which the ploughs or other instruments of culture work. I, J, are seats (supported by rods attached to the internal frames and plough-share) on which seats the ploughman sits, and from which he can regulate the progress of the plough. J, J, are two longitudinal internal frames, the remote ends of which are connected by rods or chains K, K, to an arm L, vibrating on a transverse axle M, which is centred on a rod that works in bearings in the bracket or support N. The other ends of the frames, J, J, are connected to rods N, N, which are in communication with the racks O, O, into the teeth of which gears a pinion on a shaft, which is worked by the handle R, on turning which the racks are raised or lowered, carrying with them the longitudinal internal frames J, J. There are rollers in the brackets N, N, against which the racks work in their ascent and descent. Thus, on turning the handle R, the the frames J, J, can be raised or lowered with perfect facility. A sectional view of the bracket

Digitized by Google

CHANDLER AND OLIVER'S STEAM PLOUGH.

FIG. 1.

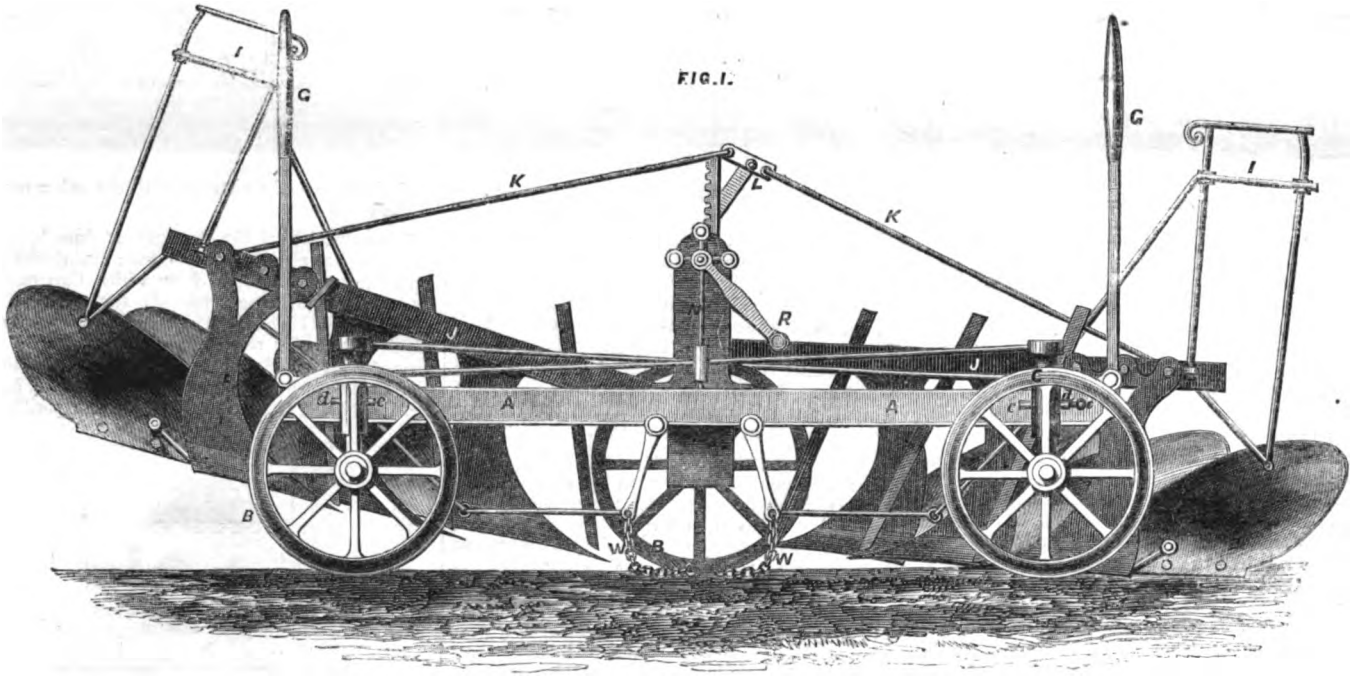


FIG. 2.

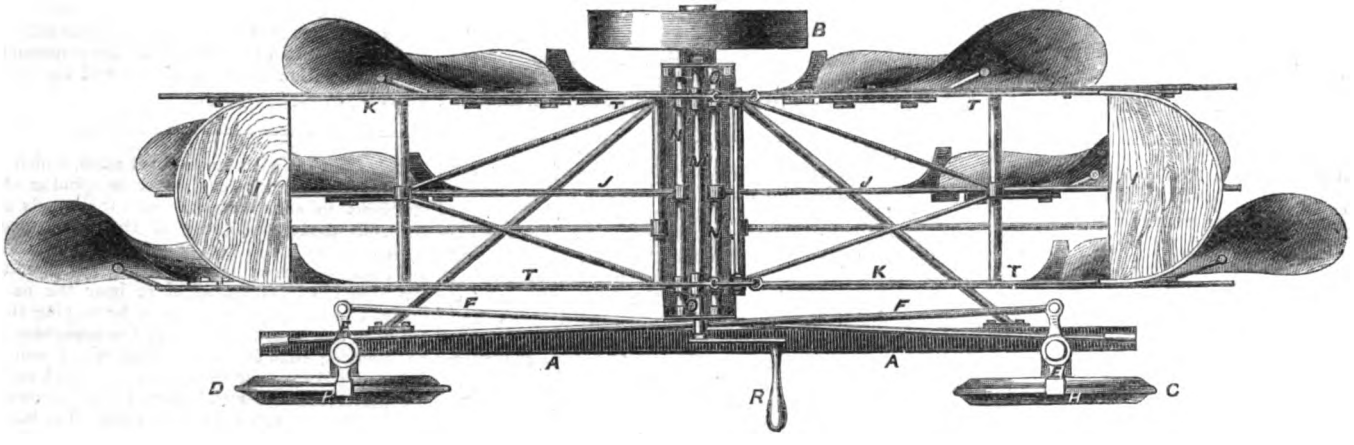
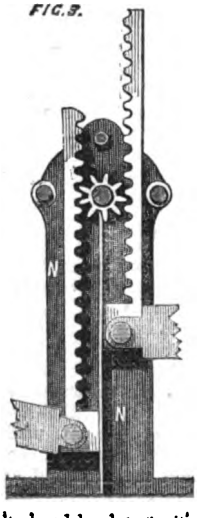


N is given at Fig. 3. There are internal frames T, T, which are on the same shaft as the frames J, J, so that they are raised or lowered as the case may be at one and the same time. To these frames J, J, and T, T, the ploughs or other cultivating instruments are attached, and are raised or lowered with the frames to which they are fastened by turning the handle R as before described. Rods or levers are attached to shafts fixed in the lower part of the brackets N, and to these rods are connected links, which are fastened to the framing. Chains W, W, pass from the rods underneath the apparatus in contrary directions, and to these chains the rope, which passes round the drums of the engine, is attached. Or the rope or chain, by which motion is given to the apparatus, may be passed over a pulley at the extremity of the internal frame.

The hauling rope or chain may be driven by any suitable prime mover, but Messrs. Chandler and Oliver prefer to employ for the purpose a portable engine, with two longitudinal winding drums, placed on horizontal axles beneath the engine. Or the engine described in the Specification of a Patent granted to them on the 25th June, 1856, may be employed with advantage for the purpose. For anchoring the hauling ropes or chains, they employ an anchor formed of a bed furnished with cutting and holding blades below, and a winding pulley or drum above, and also with a ratchet and pawl arrangement, whereby the pulley or drum may be turned round and a rope (the other end of which is fixed) be wound upon it, so as to draw the

FIG. 3.



anchor along the head-land as required, the blades cutting through the soil as the anchor advances;

THE DRAINAGE OF LONDON.

ATTENTION has again been directed to "The Great River Question," by the paper "On the Utilization of the Sewage of London and other Large Towns," read by Dr. Joule, before the Manchester Literary and Philosophical Society. Dr. Joule has been enabled to judge of the value of the works which are now being attempted; and the result of his investigation is but the reiteration of what has long been pointed out by the MECHANICS' MAGAZINE, and by almost every other paper whose sphere includes the practical application of science. It is, perhaps, of little avail that a rate-paying public, which cannot now help itself, and a Board possessed of almost unlimited powers in perpetrating and carrying-out, at a vast expense, their gigantic blunder, and which has now gone too far to retreat, should be informed that a few years must prove that the millions devoted to the drainage of the metropolis have been wasted. But in justice to those men of science and undoubted capability whose opinion has been disregarded; in justice to the Royal Commission, whose scientific suggestions, forming the groundwork of a rational plan, have been publicly ignored, but privately adopted as a makeweight in a false and pernicious system; this inevitable conclusion must be insisted upon. The discharge of the sewage into the Thames—albeit it is

Digitized by Google

effected at Barking Creek and Crossness Point—must be regarded as a fatal error in every point of view.

The conclusions arrived at by Dr. Joule are the following:—

1st. That under the new system, great accumulations of deposit would take place, which, being carried into the river by storm overflow, would continue to pollute the Thames.

2nd. That the sewage would not be entirely prevented from returning to the metropolis.

3rd. That the river would be rendered particularly noxious at the point where so vast a quantity of offensive matter was to be concentrated; and, in consequence, the large float population, as well as the inhabitants of Greenwich, Woolwich, Gravesend, &c., would suffer most severely.

4th. That the air confined in the new mains would seriously increase the already enormous volume of putrid gases in the sewers.

5th. That the system, as well as that which it was to supplement, could not be considered otherwise than very filthy; inasmuch as, instead of removing sewage to the soil, which is a natural deodoriser, it would cause its accumulation in the bed of the river, at only a few miles distance.

In dwelling upon those points of agricultural economy, the neglect of which must soon impoverish our internal resources, and lead to national distress, the author showed that the daily waste occasioned by the wholesale loss of the constituents of organic growth is, in London alone, equivalent to 2,723 tons of butchers' meat, potatoes, and bread, and 860,000 gallons of milk, beer, and other liquid food—a loss which would speedily reduce the country to a state of barrenness, were it not for the importation of large quantities of food and manure from foreign countries. But guano cannot last for ever. If the produce of the Chincha Islands, which afford it most abundantly, and of the best quality, was reserved for the sole use of Britain, they would, at the present rate of consumption, be exhausted in sixty years. The author also pointed out that with regard to the importation of cattle, corn, and bone manure, such supplies would continue only so long as foreign governments remained ignorant of the permanent injury inflicted on their own fields. Liebig has already complained that, if the exportation of bones continued at the present rate, the German soil would become gradually exhausted.

There can be no doubt that the soil of nearly the whole of Europe is becoming gradually exhausted; nor is the future, when sterility must meet the increase of humanity, so far distant as to be beyond the limits of our anxious consideration. Sterility is no necessary consequence of the increase of consumption, as is proved by the agricultural history of Holland and of China. But when the traveller from these countries, and from "New Zealand, shall take his stand on a broken pier of London Bridge," and look upon the limpid Thames, no longer bearing to the sea the rich freight of ammonia and phosphates which should give strength and life to failing crops, he may, perhaps, moralize upon the strange futuity which, in an age of science, could give nature's materials of life to infusoria and fishes. When these latter have been devoured by sea-birds, and the ammonia and phosphates deposited on ocean rocks, England may no longer require guano!

We heartily concur with Dr. Joule in asserting that we should not be satisfied with merely keeping our agriculture from decline, but that, with a rapidly-increasing population, the wisest course would be to reserve such supplies of guano as we may be able to obtain for the purpose for which it would seem to be designed by nature—that of forming a fertile soil where sterility at present exists. To effect this, we must cease to regard rivers as the "natural drainage of cities!" But it appears hopeless, in the present condition of suicidal neglect of the all-important principles of agricultural chemistry, to look forward to their adoption as a measure of policy and commonsense by the administrative wisdom of this country.

DESMOND G. FITZGERALD.

IRON-COATED SHIPS.

GENTLEMEN,—In the very excellent paper by Mr. E. J. Reed, one of the editors of the MECHANICS' MAGAZINE, recently read at the Society of Arts, upon the changes which, during the present century, the ships of the Royal Navy have undergone—a paper abounding in information and judicious observations—there is one statement to which I may be permitted to allude as not being, I think, fully developed.

In some remarks on the proposal to place the "iron armour" of ships at an inclination, and to diminish correspondingly the thickness of the plates, so as to lessen the load, it is observed, that "it needs no appeal to experiment to show that the proposed arrangement would not be attended by any advantage, for the simplest theoretical consideration shows that, for a given height of bulwark, the same quantity of metal will be required to resist a given blow, whatever the inclination may be," inasmuch as the diminished thickness would be exactly compensated by the additional extent of casing. You are well aware that caution and suspicion are entertained by me, almost to the amount of a crotchet, in respect to the truthfulness of the conclusions of mere science in their applications to practical matters, there being so much that is abstract, so much that requires modification by empirical means, before we can arrive at truth in its concrete practical reality. Can experiment be dispensed with in the present instance? I think not.

"If a shot moving horizontally strikes an inclined plane, the crushing force exerted upon the plate is equal to the crushing force which would have been exerted upon it if upright, multiplied by the sine of the angle between the inclined plate and the horizontal." Now this is true only of an abstract, non-abrading, non-crushing *blow*, upon an abstract, unimpressionable surface. If a shot exerts "a crushing force," it is retarded, more or less; and if entirely, the crushing force is wholly unaffected by the sine of the angle at which it strikes, for it is wholly spent. It is true, no doubt, of momentum, as imparted to a body in a direction perpendicular to the inclination of its surface, but only in the abstract again, upon the assumption of the collision being between perfectly elastic bodies. In a breaching force, both the direction and the amount of the components, in its alleged resolution, is altered, if not ignored altogether, and both the cause and its effects require to come under another measure besides that of momentum. A blow, to be viewed practically, must be seen in two aspects, as the result of, and measurable by, momentum, and what more especially belongs to practice, as the result of, and measurable by, *vis viva*; and it is in the latter aspect that crushing effects must be contemplated. The species and phenomena of force cannot be limited to what is observable of momentum alone; and it will depend on practical circumstances, such as the comparative hardness of the conflicting materials, on the velocity being the prominent factor in the *vis viva* of the shot, and on the particular angle at which it strikes, whether it shall freely glance from, crushingly graze, or more crushingly lodge in, or penetrate through, the iron casing of a ship; and the only investigation of these actions and their causes is the experimental.

Well, all this tends only to strengthen the position which the author of the paper has taken, "that the side of a ship will require the same weight of metal upon it, in order to resist horizontal shot, whether it be upright or inclined," inasmuch as the expedient of inclination being nullified in the case of a free glancing shot, it would be yet more useless, in case the shot should hang and tend to penetrate. This is true so far, but there may be circumstances attendant on the abrading action of a shot in an oblique direction, such as the one-sided resistance it meets with, which might, in most cases, cause it to rebound, before that resistance could be equalised on all sides by sufficient penetration; and this would depend on those practical circumstances just mentioned, the effect of which experiment alone could determine. Now, the perforation by shot is, I apprehend, the great thing to be dreaded, and it is possible they may be turned aside by the obliquity of their action under the conditions specified, although without that expedient they may not. If, however, the author means by "crushing force" not that which is exerted in the penetration of the plates, but that which is the result of the blow, in the rending or crippling of the timbers to which they are the casing, then these observations are altogether in aid of his argument.

The great enemy which these tortoise ships of war will have to contend with, is the rifled cannon with steel shot—that is, if bursting can be prevented—for here the velocity of the projectile is prodigiously increased, and it is according to the *square* of the velocity that its destructive effects must be estimated. Hence, a pretty close proximity will always be necessary in an attack on these tortoises, and an armament with a long range will constitute at once their security, and their dangerous character as a foe.

I am, Gentlemen, yours, &c.,
BENJ. CHEVERTON.

PENETRATION BY ELONGATED RIFLED IRON SHOT AND SHELL.

GENTLEMEN,—In the highly instructive and valuable paper read by Mr. Reed, at the Society of Arts, on the evening of Wednesday last, he makes the following observation:—"It is a defence against shells and hollow-charged projectiles generally, and against those only, that iron plating can yet be made available. By applying iron of very great thickness between wind and water, we may reduce the liability to injury by shot to that important part; and it may be well to do this; but if the upper works are made shell-proof, we can export no more. These considerations reduce the question to a form in which it may be practically dealt with, and I doubt not the solution is not very distant."

As I was invited by a letter of invitation from the Secretary, by order of the Council, to take a part in the discussion, I wished to say that, from experiments I made at Cork, nearly seven years ago, with the two-groove 14-bore service rifle of that period, in presence of several members of the council of the National Exhibition held there; and from the results of those experiments I felt confident that rifled cannon would sooner or later be adopted in the service; and the wonderful range and accuracy of fire obtained by Mr. Armstrong's rifled cannon fully bore me out in my expectations. But as, from some misconception in the mind of the Chairman, I was not allowed to proceed, I now beg to state that, judging by the results of those experiments, no iron armour can be put on a man-of-war that will be a protection against elongated iron shot and shell, formed after the manner of those I experimented with at Cork, although iron armour would be a protection against Paixhan's shells. An extract from Col. Beamish's letter to the editor of *The United Service Journal*, of August, 1852, fully and clearly explains the nature and results of those experiments.

I am, Gentlemen, yours, &c.,
Rosherville, 20th Dec. J. NORTON.

FINE ARTS.—We understand Mr. Greville Fennell has been experimenting on hard and soft vulcanite, in order to make it subservient to the uses of the artist, as a medium for receiving oil colours. We hope shortly to publish an account of all his experiments. Mr. Fennell intends liberally to present the result of his labour to the profession.

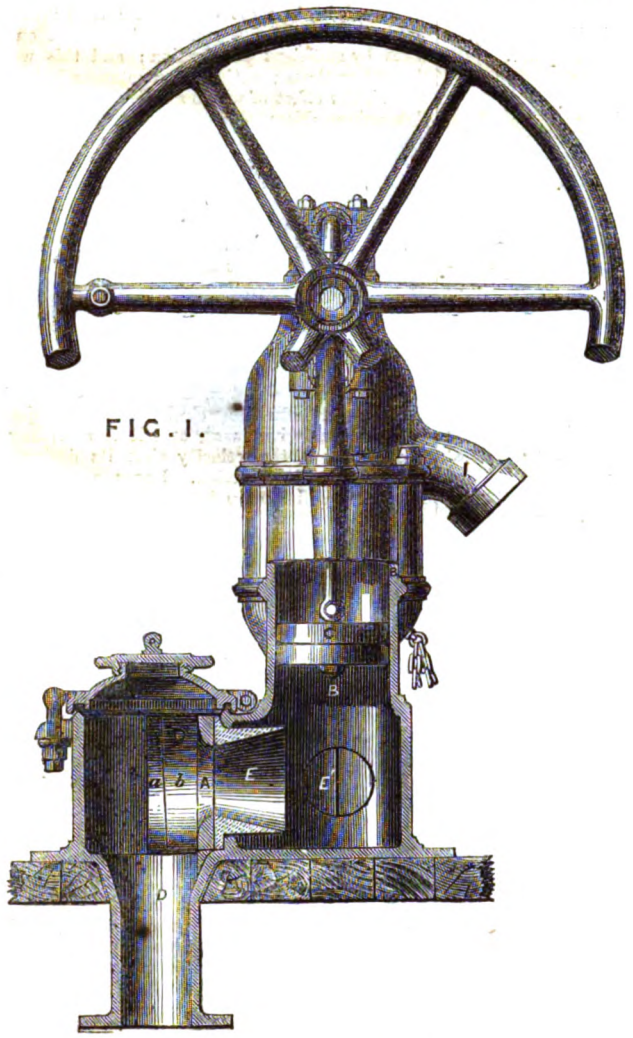
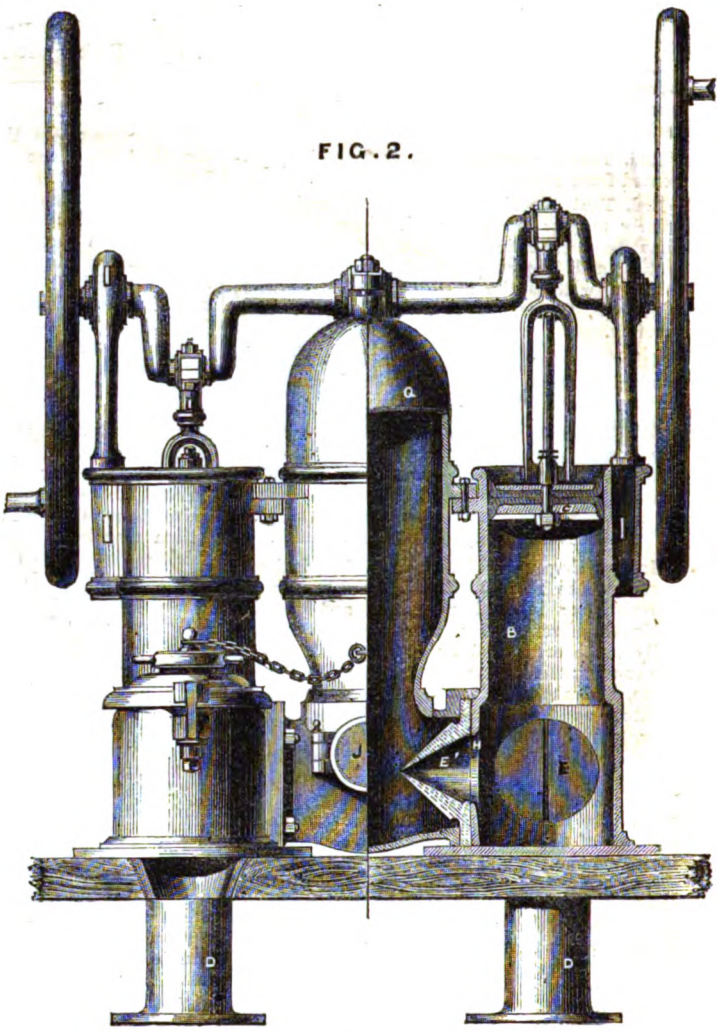
SUFFIELD'S IMPROVED SHIPS' PUMPS.





SUFFIELD'S IMPROVED SHIPS' PUMPS.

WE have had numerous improvements in ships' pumps lately, for which we ought unquestionably to be grateful. No disaster can be more appalling than the sinking of an inhabited ship at sea, unless it be the burning of such a ship, and it is to the pumps that we have, of course, to trust, in the event of accident, for security from both these evils. The extent to which the ocean now swarms with passenger ships renders us eager to embrace every real improvement in these appliances, however modest and unpretending its character may be. For this reason we bring an improved pump, arranged and manufactured by Messrs. Suffield and Co., of Bermondsey-wall, to the notice of our readers. This pump has no very remarkable novelties embodied in it. Its great merit lies in its careful adaptation, by a person of great practical experience, to the varied requirements of service on board ship. For many purposes, where the duty is not too severe, Mr. Suffield fits his pumps with Perreaux's valves, which are now becoming well known, and specimens of which may be seen in operation at the South Kensington Museum. We recently witnessed the working of the Suffield pump, fitted with these valves, and found the results truly astonishing. The great and most characteristic merit of a pump is the liability it has to choke. The advantage of the Perreaux valve in this respect is well understood; and, on the occasion just referred to, we saw bulky pieces of sacking, workmen's jackets, and other like articles, drawn completely through the pump, without any evil effect whatever, and without any kind of difficulty.

In the annexed engravings we have represented, in fig. 1, a side elevation partly in section and in fig. 2, a front view one-half in section, of one of Mr. Suffield's pumps, fitted with Perreaux's valves, and arranged for working with cranks, fly-wheels, and common handles. The channels, AA, are formed separate from the barrels, BB, in which the plungers, CC, work. The passages, AA, from the suction-pipes, DD, to the barrels, BB, are fitted with valves, EE, opening inwards towards the barrels. *aa* are castings or feathers, and *bb* wedges for keeping the valves in their places. The delivery from the barrels takes place through ports, HH, fitted with other valves, E'E', opening outwards into a common pipe, fitted with a dome or air vessel, Q, and with two screwed collars, I and J. For pumping purposes, the under-collar, J, is closed by a screw-cap, and the delivery takes place through the upper collar, I. On the contrary, when the pump is to be used as a fire-engine, the upper collar I, is closed, and the hose is screwed on to the under collar J, the upper part of the vessel forming an air-chamber.

Although we have spoken of these pumps mainly as ships' pumps, they manifestly need but little modification to adapt them to various other purposes. When fitted on board ship, suction-pipes are led from various parts of the ship, and their upper ends are all brought together in a casting, close to the main suction-pipe leading to the hold, and are all furnished with screw-caps to close them. Then, by means of a goose-neck, or other suitable coupling-piece, the pump may be connected to either of the suction-pipes, and thus made to draw from any part of the ship.

At the trial of the improved pump referred to above, we were unable to institute any comparative tests with existing pumps; but the flow kept up by a few men from a depth of many feet was so copious and so uniform as to leave but little doubt of the efficient working of the machine. Indeed, it was the opinion of one very experienced engineer who was present, that he had never before seen results equal to those then obtained, and we must acknowledge that his opinion was not formed without considerable reason. The demand for the improved pump—proceeding, as it does, from a well-known firm of great practical experience—is so great that several dozens are now in progress of manufacture.

We have said that Mr. Suffield uses the Perreaux valve where the duty is not too severe. He does not, however, confine himself to the use of this valve, but prefers, in some cases, other valves of an improved description.

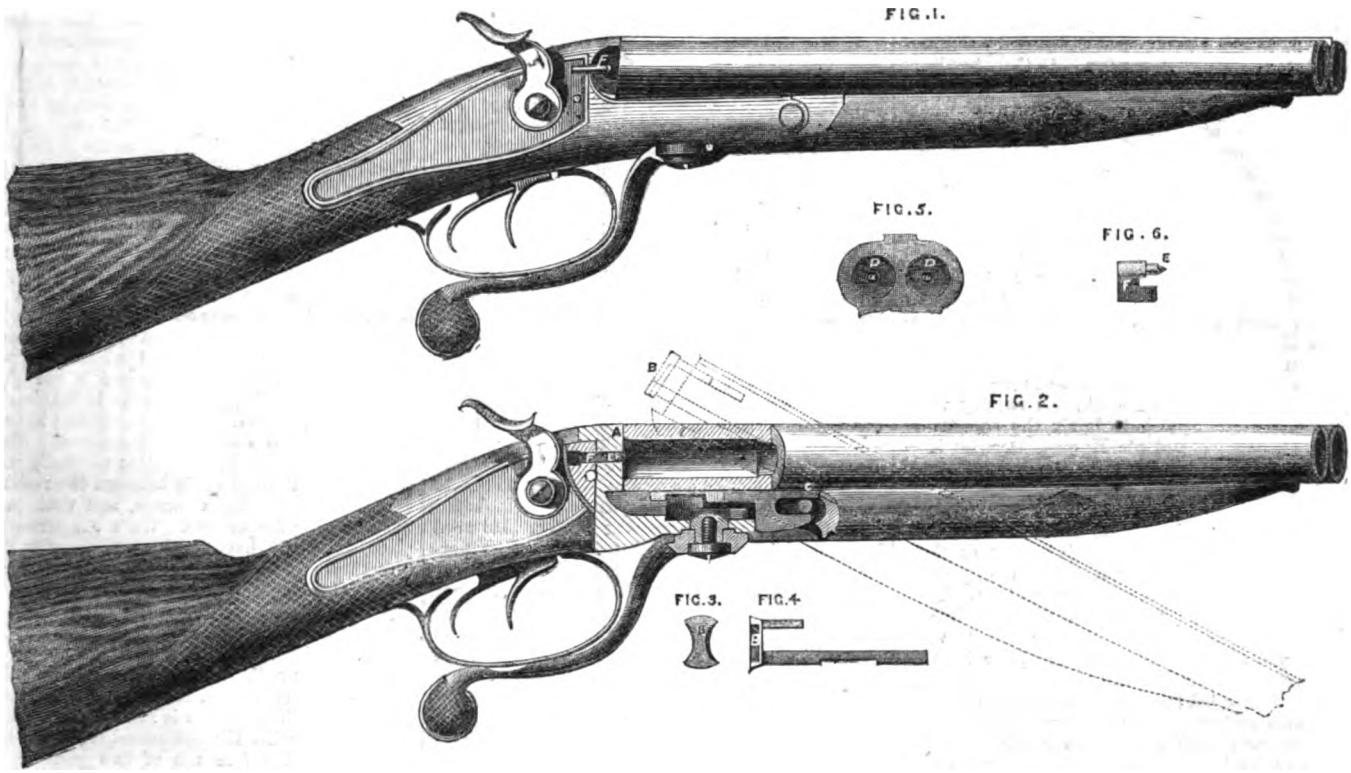
LANCASTER'S BREECH-LOADING RIFLE.



LANCASTER'S BREECH-LOADING RIFLE.

MR. Charles W. Lancaster is universally known, both as a manufacturer of first-class guns, and as an inventor of valuable improvements in small-arms as well as ordnance. But his latest improvement, an admirable breech-loading rifle, has not yet been brought to the notice of the public, although it has already gained golden opinions from sportsmen. This rifle is of that class in which, when the piece is to be loaded, the barrel is drawn forward from the breech, and turned down, so as to present its rear end to receive the charge; and Mr. Lancaster's improvements are four in number. They consist, First, in undercutting the abutment or stationary breech against which the barrels rest when ready for firing, and in cutting the rear of the barrels to correspond, in such manner that when the barrels and breech are in contact, the overhanging part of the breech prevents the rear of the barrels from rising. Secondly, in forming sunken recesses in the inclined face of the breech, to enable the rear end of the cartridges to be supported in their own plane, that is, square to the bore. Thirdly, in fitting the strikers, which carry the points for exploding the cartridges, without springs, the points and strikers being pushed back by the cartridges coming in contact with the points when the rear of the barrels is forced home in the breech. And, fourthly, in constructing the extractor or instrument whereby the cartridges are pushed out from the rear of the barrels when they are tilted preparatory to re-loading, in such manner that it (the extractor), takes the cartridges at two points, and embraces a considerably larger portion of the capsule or rear of the cartridges than heretofore.

The annexed engravings represent these various improvements. Fig. 1 is a side elevation, and Fig. 2 a side elevation partly in section, of so much of a double barrelled gun as is necessary for the elucidation of the invention. A, is the face of the stationary breech. The dotted lines, Fig. 2, show the position of the barrels when tilted prior to re-loading. In this position the extractor B is protruded from the rear of the barrels by its frame coming in contact with the fixed projecting stud S. The extractor seizing the rear of the cartridges at B carries them partially out of the barrels, the fingers being employed to remove them entirely. Face and side views of the extractor B are shown separately at Figs. 3 and 4. Fig. 5 is a front view of the face of the breech. D D are the sunken parts for the reception of the rear of the cartridges, E E are the points (shown separately in side view at Fig. 6) which work in holes *a a* formed in the centre of the sunken surfaces. These points are formed in a piece with the strikers F F, which are free to move to and fro in recesses or slots formed for their reception. They are moved forward by the action of the hammers to explode the cartridges through the points E E, and upon the hammers being raised they are pushed back by the capsules of the freshly inserted cartridges, ready to be again driven forward, as before explained. With this rifle, escape of gas at the breech is rendered impossible, the metallic end of the cartridge remaining intact during the discharge.

NAVAL WARFARE WITH STEAM.*

IF an expert swordsman had a friend who was about to fight a duel, he might show his love of the science of fencing, and might also contribute towards its advancement, by imparting his knowledge to both the combatants. But such impartial conduct would hardly be considered friendly by the man who had claims upon his consideration. If we suppose, moreover, that the friend of the scientific adviser possessed greater quickness of eye and strength of limb than his opponent, and placed his confidence in this superiority, he would have additional ground of complaint. In like manner we doubt not, when it is remembered that the English navy has always, and justly, cherished such a confidence as this, many naval officers will regard the publication of Sir Howard Douglas's advice on steam naval warfare as injudicious.

He says, at the close of his book—"It is hoped that the principles inculcated in this work will be found sufficiently intelligible to enable a good tactician to apply them in any form of battle which he may initiate, or which he may assume, either for the purpose of counteracting any measures taken by the enemy, or to take advantage of any false movement which he may make"—the enemy spoken of being, of course, the opponent of the *good tactician* who studies Sir Howard's work, and who may be an Englishman, but is just as likely to belong to the nation of whose periodic fits of sans-culottism and imperialism we are supposed to stand in jeopardy every hour. But we must plead as an excuse for our author, the peculiarities of the warlike constitution of the British seaman; and the plea will doubtless be deemed amply sufficient. The characteristic habit of our navy, associated with all its traditions, seems ever to have been to consider circumspection and caution as indicative of weakness, and to scorn, as dishonourable artifice, the use of that strategy which constitutes the skill of the *military* commander. As soon as the enemy appeared in sight the English officer thought himself bound to bring them at once to close quarters, and put all to the issue of a hand-to-hand combat, even although the longer range of his guns, and his inferiority in numbers, showed such a course to be unwise and dangerous.

The English admiral has, from the days of our earliest triumphs, strained every nerve to obtain the weather-gage of a hostile squadron, that he might cut through its line, grapple his enemy to leeward, and prevent all chance of escape. The continental chiefs do not seem to have thought it necessary to take any such means for securing a fair fight, but satisfied themselves with such a disposition of their forces as would do most damage to their rash opponents.

So at Trafalgar. "Admiral Villeneuve," says one of Nelson's biographers, "made his own disposition with the utmost skill, and the fleets under his command waited for the attack with perfect coolness." Sir Howard says—"Villeneuve's nautical science was in advance of the practical methods of that day; and it did present great obstacles to the success of Nelson's plan of attack;" and further,—"There can be no doubt that the novel formation which Villeneuve attempted, though frustrated by the disabilities of the sail, shadows forth the adoption of this order of battle which the author

* "On Naval Warfare with Steam." By General Sir Howard Douglas. Murray.

Digitized by Google

has endeavoured to propound, and which will undoubtedly hereafter become an established formation in steam warfare." The English fleet was in two parallel lines—the windward one led by Nelson, in the *Victory*, and the other by Collingwood, in the *Royal Sovereign*. As these two lines advanced, at about a mile-and-a-half per hour, each of the foremost ships, the bows of which were square and thinly planked, was under the raking fire of the broadsides of eight or nine ships, consisting of hundreds of guns. Before the *Victory* could reply by a single gun, she had lost fifty men, and had her main top-mast, with all her studding sails and booms, shot away. After having been under fire forty minutes, she reached the enemy's line, and ran into the *Redoutable* just as her tiller-ropes were carried away by a shot from that ship. Admiral de la Gravière thinks that, with ordinary gunnery practice on the part of the French and Spaniards, Nelson would have seen his ships smashed to pieces by those of the French, like cavalry when improperly attempting to break the squares of steady infantry; and Sir Howard Douglas is of opinion that, "if the present improved state of gunnery had existed then, the divisions of the British fleet would have been entirely disabled before they came to close action." What is more manifest than that such actions as these were won by sheer "pluck," in opposition to, and in contempt of, scientific strategy. Thus it has ever been. The Dutch, the French, and the Americans have done their naval work scientifically; and, although they have been so overmatched in the end that the foremost amongst them is compelled to say, "*Je ne suis pas de ceux qui dans l'illusion de l'amour-propre nationale, nous croient en état de lutter sur mer d'égaux à égaux contre la puissance Britannique*,"* yet they have made their self-confident enemy suffer severely for his rashness. But, while Englishmen have been thus neglectful of naval strategic science, France has given birth to Paul l'Hoste, a man who may be said to have been its creator; and among her sons are still to be found some of its ablest expounders.

Hitherto the great difficulties in handling sailing ships, and the capricious nature of the elements on which success depended, have frequently deranged the most skilfully-devised plans of operation, and rendered anything like complexity uncertain and dangerous. Ships in order of battle have formed in lines ahead or in lines abreast, and there was but little else they could do with anything like precision.

"But steam propulsion entirely annuls all the limitations and disabilities imposed by the wind on the evolutions of fleets, and opens the whole surface of the ocean as a battle-field for the contests of steam fleets. . . . . The movements of steam fleets may, like those of armies, be conducted on tactical principles best adapted to the great end of all preliminary manœuvres—the formation for battle in the most simple, speedy, and precise manner. This power of executing the evolutions of fleets and armies on the same tactical principles, cannot but be considered as one of the greatest benefits which will result from the application of steam propulsion in naval warfare. The intended formation may, in all cases, be accomplished by steam fleets, with as much precision as the formation of an army on land, and with the like regard to the avoidance of a premature display of the whole force, or a disclosure of the intentions of the commander. . . . With this new power it may be presumed that success will more than ever depend upon the tactical skill and the quick perception of the chief, together with prompt and resolute execution on the part of hos: under his command."

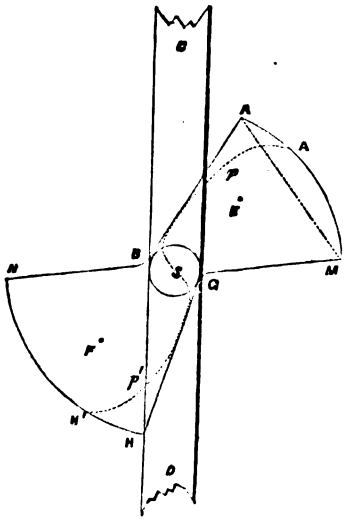
"Naval officers of the old school," says our author, "may at first sight be disposed to repudiate, perhaps to ridicule, the adoption, in their profession, of the principles of military movements and formations, as recommended and expounded by the author. But, moved as fleets will hereafter be, by the obedient agency of steam, so that the station of each ship in a fleet, and the time to be occupied in performing any evolution, can be determined with as much exactness as the post of a regiment or brigade in an army, it must follow that the evolutions of ships of war will be susceptible of being executed with a precision hitherto unknown in the naval service. . . . The rude practice of forming a fleet for battle in one long line has hitherto prevailed in naval warfare, on account, chiefly, of the difficulties and uncertainties imposed by the wind, in executing compound evolutions with sailing ships. These difficulties will not exist for fleets consisting wholly of steam-ships. Armies in the field move in as many columns as there may be practicable roads or opened routes leading to the point at which the intended deployment in order of battle is to take place; but at sea a steam fleet may always be moved in as many columns as there are divisions in its formation, and each ship of a fleet may be considered as corresponding to a batalion in a land army."

If this be true, it is of the utmost importance that our naval officers should set themselves in earnest to the study of naval tactics, which we have the highest authority for saying they have not yet done. Sir Howard Douglas, in the work before us, shows carefully, clearly, and as fully as his limits permit, how the principal military manœuvres may be made available in naval actions.

The former half of the book is taken up by a brief history of the introduction of steam as a moving power to ships, and "an account of the nature and action of steam machinery in its application to the paddle and the screw, together with an inquiry into the relative values of these agents with respect to their powers of communicating motion, and to their conveniencies in the armament of ships of war." Of this part we can say but little. The latter half—on naval tactics—forms an admirable supplement to Sir Howard's incomparable work on "Naval Gunnery." If we might presume to offer advice to Sir Howard, we should say the sooner it is incorporated with that work the better. He need have no anxiety about the fate of the other portion, as it will, in our opinion, never do him any abiding credit. After this statement of our opinion, minute criticism is unnecessary. There are, however, two things in it we should like to notice. One has reference to the tremulous motion of the sterns of screw-ships, and the other to the use of the trunk in screw-ships of war.

The author says, on the first point:—

"The shake of the screw, and the consequent injury to the stern of the ship, are caused by the sudden and violent reactions of the disturbed water in that place against the blades of the screw as they enter and emerge from thence. The rectilinear edges of the ordinary screws are, in this respect, highly disadvantageous, since the whole of an edge enters and leaves at once the water on each side of the aperture; within which aperture the water is comparatively in a quiescent state; but if the leading edges of a screw-blade were curved, as A' pB, Gp'H', in the figure, they



would slide obliquely and continuously through the water, like a screw formed with an entire feather, so that at no moment would there be any shock or discontinuity of action." Page 60.*

We are afraid that Sir Howard's screw would do very little towards reducing the shock complained of; for the ordinary practice of using two small portions of a screw surface instead of an entire thread has two effects, against which he makes no provision, but which are undoubtedly the main causes of the shocks. The first is, that when one blade of the screw comes vertically over the other, a body of water is driven against the after stern-post, and is brought to rest by the resistance the post offers to it. The tremor of the stern has been, in fact, considerably diminished by fitting angular pieces of wood on the foremost face of this post, and is said to have been almost entirely removed in some cases by working the screw abaft the rudder. The other of these causes is, that a quantity of water is driven off *sideways* by the blades of the screw, as well as fore-and-aft—the upper blade driving it in one direction, the lower blade in the other. If these two forces were exactly balanced, the stern would not be moved towards either side. But they are not so balanced. The water driven off by the upper blade moves much more freely than that acted upon by the lower one. The upper blade is, in fact, not unfrequently partially out of the water. The consequence of this is, that at every semi-revolution an unbalanced pressure is brought on the screw in the direction opposite to that in which the lower blade moves. This is equivalent to a series of blows on one side of the stern-post. Similar forces are also brought into action vertically in consequence of the difference between the resistance on the blade moving upwards, and that on the blade moving downwards. Were the screw complete, we should have continuous pressures in the directions named, instead of the more mischievous intermittent ones. But it will be seen at once that the alteration in form proposed by Sir Howard would not tend to diminish any of these forces.

Again, our author has conceived a violent dislike to the trunk or framework round the well through which the screw is raised. He says that it interferes with the armament of line-of-battle ships, where the free use of two guns on each deck is, on this account, greatly impeded: consequently, he says, there may be said to be only two stern-guns on each deck which are wholly effective. Now, we do not think that this objection is well-founded. It is true that there are only two guns on each deck of our screw line-of-battle ships which can fire in the line of the keel, and therefore which are effective as stern-guns; but that this is not owing to the presence of the trunk may be seen from the fact that our sailing ships have no more. The statement that "by suppressing the trunk, the stern-batteries on each deck would be strengthened by the two guns which the trunk had rendered useless," is without foundation.

He says, also:—

"The steerage of the ship is greatly impeded by the intervention of the trunk, which renders it impossible to use a long tiller, and permits only the substitution of two short arms of a lever, called a yoke, which works within the small space between the trunk and the stern. . . . . The arms of the yoke being short compared with the length of an ordinary tiller, it has been found necessary, in order to obtain sufficient power to turn the rudder, to have a multiplying purchase consisting of a system of pulleys near the end of each arm of the yoke, and also in a main beam in its rear. In consequence of the complexity of this apparatus, a *considerable revolving motion of the steering-wheel* is necessary in order to produce even a small movement of the rudder; and there is therefore a want of promptitude in the corrective power of the helm, when moved by the yoke, which is not experienced when a ship is steered by a simple tiller in the ordinary way." And again, "the *great force which it is necessary to apply to the wheel* in order to give motion to the rudder, particularly when the latter is acted upon by sudden and violent impulses from the striking of waves against it, is also the cause that the steering of screw steamers having trunks, is far less steady than that of ships whose helms are managed by the ordinary tiller."

Are not these statements self-contradictory? There is a certain work to be done by the man at the wheel—viz., to overcome the resistance of the water to the motion of the rudder through any given number of degrees. Now, whatever be the nature of the machinery intervening between the man and the rudder, he must—neglecting friction—perform exactly this amount of work. Representing, then, the work done at the rudder by a certain quantity, consisting of pounds multiplied by feet, he performs this quantity by moving a less number of pounds through a greater number of feet—the nature of the machinery regulating the *relative* numbers of pounds and feet. If by

* The Prince de Joinville, in his famous *Note sur l'etat des Forces Navales de la France*.

* Sir Howard says further that these curved edges would also have the advantage of readily throwing off any floating materials that may come in contact with them. He proposes, also, that the curved parts should be furnished with sharp edges, partly notched like saws, and made of a metal capable of resisting the corroding effects of sea water, by which means they would be rendered capable of dividing any rope, spar, or other floating matter, like a powerful circular saw.

Digitized by Google

using the yoke "a considerable revolving motion of the steering-wheel is necessary"—*i. e.* if the number of feet is greater than when a tiller is used—it is impossible that it should be necessary to apply greater force to the wheel. Unless it can be shown that there is more friction in the yoke than in the tiller arrangement, we must conclude that it is possible to work the rudder by the same power and with the same promptitude. The amount of friction will depend only on the number and position of the sheaves, and it is quite possible in most cases to make as good an arrangement for the yoke as for the tiller. In fact, it is the practice in the Royal navy to make the rudder go hard over, *i. e.* through 35°, by 3½ turns of the wheel, whatever be the nature of the steering apparatus. We do not deny that the sheaves are frequently so badly placed as to impair the efficiency of the yoke. The yoke-arm and the fixed block are allowed to come so close together when the yoke is hard over, that the ropes of the pulley lose their parallelism, and get jammed. There should always be at least 18 inches between the sheaves in the yoke-arm and in the stern when the rudder is hard over. If this were attended to, we should hear no more complaints about the yoke. It would be as effective in a line-of-battle ship as it is in a gig.*

Sir Howard speaks also of the great force of torsion exerted by the yoke on the rudder-head tending to wring it. He surely cannot wish us to believe that a tiller is less injurious?

With reference to the trunk, we do not doubt that naval officers would be very glad to get rid of such an incumbrance from their cabins; but they would find it rather unpleasant work to raise the screw in bad weather were it suppressed.

We must say a word or two, in passing, on the question of *slip*. We have always understood the slip of a screw to be the ratio of the *loss* shown by the difference between the velocity of the screw in advance and that of the ship, to the *velocity* of the screw in advance. We may cite as an authority to this effect a work quoted as such by Sir Howard, "The Marine Steam Engine," by Brown and Main, 2nd Edition, (the definition and investigation in the 1st edition, p. 270, are incorrect.) But, according to Sir Howard, *slip* is the recession of water from behind the screw. He says:—

"If the water re-acted upon the screw of a steamer precisely as a nut re-acts against the threads of a screw which works in it, the vessel would move through a space equal to the pitch of the screw in the time that the latter makes one revolution on its axis; but such speed is not realised in practice, first, on account of the recession of the water (the slip) from behind the screw, after being acted upon by the latter; secondly, the water in advance of the screw is not free, &c., &c." Page 42.

It is really an important thing to endeavour to preserve scientific terms from corruption—we shall otherwise get into endless confusion. One of the consequences of this very misapprehension on the mind of the author is, that he attempts to show how this slip may become negative—the ship being propelled by the engines only. (Page 37.) We must point out also one very serious misstatement of facts in the latter portion of the book, which has evidently arisen from the loose way in which the term bow-gun is used among naval men. Sir Howard says:—

"A line-of-battle ship fully armed at bow and stern, as well as on her broadsides, has no dead points, since she can bring guns to bear in every direction about her. The bows of such ships are armed with a 68-pounder solid-shot pivot-gun, and there are, besides, *four bow-guns* on each deck." . . . . "Thus, the bow-batteries of a two-decked ship consist of *nine* heavy guns, and those of a three-decked ship of *eleven*. Though ships of the line are thus really strong at bow and stern, these are technically called the weak points." . . . . . "When a fleet is ranged in order of battle called line ahead, a great amount of gunnery power in the bow-batteries is utterly out of action; this, in a fleet of twenty ships of the line, of which six may be three-deckers, will amount to 152 heavy guns, whose fire is masked by the leading ships."

It may be seen from these quotations that by bow-guns Sir Howard understands those which can be fired in the direction of the keel. But we can assure him that there is not a line-of-battle ship in the whole service that has more than two such bow-guns on a deck. We are afraid there are but few which have even these, and that some of our modern line-of-battle ships have nothing but the pivot-gun, which can be fired in the direction of the keel.* But the importance attached by him to these guns in the formation of line-of-battle *en échelon* shows how wrong it is to weaken this portion of the ship's armament. The trifling advantage gained in speed, by increasing the fineness of the bows of our two and three-decked ships, can never compensate for the consequent weakness of their bow-batteries.

We must now bring our notice of the book to a close. It is, in all probability, the last work which its distinguished author will give to the country he has served so long and so well—for he is more than four-score years of age. Yet the book bears no evidence of this, but is, on the contrary, clearly and vigorously written, and will form a most useful companion to the indispensable "Naval Gunnery." It will have the effect of arousing the attention of naval officers to the importance of the subject treated, and will, we doubt not, be the precursor of more elaborate treatises on naval tactics. One present effect which it ought to produce is, the appointment of a commission of naval officers — or, perhaps, a mixed commission of naval and military officers would be better—to consider the changed tactics which the introduction of steam has rendered essential. We know that this subject is weighing anxiously upon the minds of some of our most intelligent and patriotic commanders, from our Admirals downwards, who justly fear that our present neglect of the question may prove disastrous to us in the event of a naval war. All honour is due to Sir Howard Douglas for his zealous and able effort to concentrate attention upon this vital point, and we earnestly hope the Admiralty will avail themselves of the feeling created by the appearance of his work and appoint such a commission as we have suggested, or by some other means provide for the enlightenment of the naval service upon its new duties.

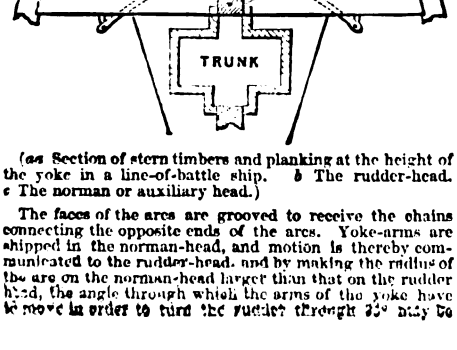
The Literary and Educational Year-Book for 1859. London: Kent and Co.

WE have just seen the proof-sheets of this most valuable book of reference. It is just the thing which literary and scientific people very much wanted, containing, in a concentrated form, an immense mass of useful information—such as lists of all the books published during 1858, with the size, price, and publisher of each book; lists of all metropolitan and provincial newspapers and periodicals, stating price, day of publication, and peculiar politics, or nature of each; lists of the year's maps and prints; the names and addresses of nearly a thousand professional and gratuitous lecturers of the country, with the subject treated of by each person; lists of mechanics', literary, and other educational institutions. It also gives the names of all the successful candidates of the Oxford middle-class examination, and similar information relating to the Society of Arts Union of Mechanics' Institutes, and what, perhaps, will be considered still more valuable matter to some people, viz.; the requisite information referring to the next final examination, including instructions to candidates, subjects on which they will be examined, and the authorised books which they may consult to prepare them for the contest. The book also contains a great deal of information on the learned and scientific societies of London, giving a kind of birds'-eye view of the nature, objects, and present condition of each society. Take, for instance, what it says about the Institution of Civil Engineers. It first gives the name and address of the Institution, then when it was founded and incorporated by Royal Charter, the names of the council and honorary councillors, and a *resumé* of the general objects of the institution; then follows information about election fees, annual subscriptions, the time when the library is opened, the president's *conversazione*, &c.; and lastly, we have the titles of all the papers read before the Society during the session 1857 and 1858, with the name of the reader of each. Almost every other learned institution of the metropolis is treated in a similar manner. Our space will not permit us to specify the varied kinds of reference matter with which the book abounds; but we must not omit to notice that it contains the list of works printed by order of the Commissioners of Patents for Inventions, including chronological indices and classified abridgments of all specifications of patented inventions, from the earliest enrolled to those published under the act of 1852, and the places where such works may be daily consulted in the United Kingdom. After this hasty glance at the contents of the book, it only remains for us to recommend it to each reader, as by far the most voluminous, complete, and accurate compilation of the kind that has ever yet appeared. It deserves to sell, and we doubt not will sell to an unprecedented extent.

---

* There are cases in which the space between the trunk and the stern is so limited, that not only is there no possibility of preventing the jamming of the ropes when the yoke is hard over, but it is even found necessary to cut into the angle of the trunk and into the stern-timbers, and to put the blocks outside the ship in order to get the rudder over 32°. This is the case in the *Agamemnon*, and some other line-of-battle ships. That this is highly objectionable there can be no question. There is, however, a model at Somerset House, showing an ingenious and practicable mode of avoiding this by means of multiplying gear. A portion of the head of the stern-post is cut off, and an iron norman-head, 18 in. or 2 ft. long, is fitted between the under-side of the after-beam, which is generally about 2 ft. before the rudder-head, and the top of the stern-post. Both the norman-head and the rudder-head have a portion of an arc of a circle worked on the front of them, the circumferences of the two arcs touching each other, as shown in fig. 1.

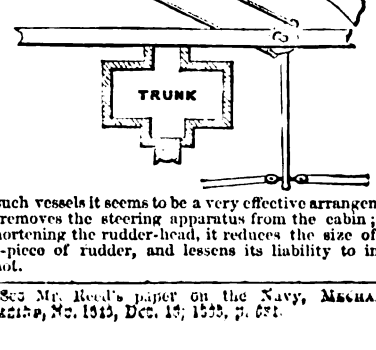
FIG. 1.



(*a*a Section of stern timbers and planking at the height of the yoke in a line-of-battle ship. *b* The rudder-head. *c* The norman or auxiliary head.)

The faces of the arcs are grooved to receive the chains connecting the opposite ends of the arcs. Yoke-arms are shipped in the norman-head, and motion is thereby communicated to the rudder-head, and by making the radius of the arc on the norman-head larger than that on the rudder head, the angle through which the arms of the yoke have to move in order to turn the rudder through 35° may be reduced to any extent that may be required. As we have already explained, the only loss experienced by such an arrangement would be by friction. The chains need only be of the same strength as the threads of the screws by which the lugs in ordinary yokes are set up. Admiral Martin, one of the present Lords of the Admiralty, has an arrangement to effect a similar object. It appears, however, to be only applicable to frigates and similar vessels, as it is to be fitted below the lower deck, and the rudder-heads of larger vessels pass out through the counter above or at the lower deck; there would also be great objection to its use in a cabin. He fits in the *Termagant* (the experimental vessel,) a norman-head between the ship's counter and the under side of a lower-deck beam, and at such a distance from the middle of the ship as to allow a tiller to work on one side of the trunk. Motion is communicated from the norman-head to the rudder-head by means of two bars of iron attached to lugs on the sides of the norman and rudder-heads (fig. 2).

FIG. 2.



For such vessels it seems to be a very effective arrangement, as it removes the steering apparatus from the cabin; and by shortening the rudder-head, it reduces the size of the main-piece of rudder, and lessens its liability to injury by shot.

Numbers 1845 and 1846 of the MECHANICS' MAGAZINE (original series), containing the paper read at the Society of Arts, December 15, 1858, "ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWERS OF ATTACK AND DEFENCE," by one of the EDITORS of this Magazine, together with the discussion upon the same, are still on sale.

The publication of an illustrated article on BLACKBURN'S GREAT STEAM TRACTION ENGINE, which was to have appeared in this Number, is unavoidably deferred for a short time.

NOTICE TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 6d, per line for any number of insertions less than 13; for 13 insertions, 5d. per line; and for 52 insertions, 4d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can be received after 9 o'clock on Friday morning for the ensuing number.

NOTICE TO CORRESPONDENTS.

☞ The practice of publishing a vast quantity of fictitious Notices to Correspondents has become so general in cheap journals, that the public, who are not in the secret, have come to consider it the duty of Editors to answer any and every question that may be put to them by readers. This cannot, however, be done in a journal like our own without entailing an immense amount of labour (often of a very unnecessary character) upon us. We, therefore, beg most respectfully to decline the task. But in order that our correspondents may not be deprived of all advantage in this respect, we shall, as a rule, publish such queries as may be sent in good faith to us, though not such as appear to be sent merely for the sake of giving trouble. To the published queries other correspondents will, we hope, reply, and their replies shall likewise be published. By this arrangement we shall save ourselves much inconvenience, and at the same time secure, we trust, to our readers all the information they may desire. All questions must be stated simply, clearly, and without circumlocution of any kind; and we shall feel grateful to those correspondents who kindly take the trouble to send such information by way of reply as they may possess. Mere questions of business we shall of course answer ourselves; but whenever calculation, reference to published works, &c., are necessary, we shall dispose of the questions sent as stated above.

CORRESPONDENTS' QUERIES.

Gentlemen,—Please to allow me to make the following enquiries through your pages:—

How must I proceed to set out a sweep for striking out a screw with an increasing pitch? I use the hypothenuse of a right-angled triangle for the common screw, and I know the line will be a curve for an increasing pitch, but how am I to find that curve and set it out?

2. The distance between the tubes of a tubular boiler is a constant quantity, *d*; what must be the diameter of the tubes so that I may have a maximum of heating surface?

3. If I suddenly compress a quantity of atmospheric air to half its bulk, what heat will it be raised to?

Your's respectfully, A PRACTICAL ENGINEER.

ON THE CONSERVATION OF FORCE.

GENTLEMEN,—You will remember that some little time ago a discussion took place in your pages on the above subject, as taught by Professor Faraday in a lecture previously delivered at the Royal Institution. You will remember, too, that you permitted me to take part in that discussion. Wishing to learn something further of this doctrine from its leading professors, I have been recommended to read Mr. Grove's essay on the *Correlation of Physical Forces*, and a paper by M. Seguin, read before the French Academy, and published in *Cosmos*. I have perused both these performances, and wish to offer you a few remarks on their respective merits, hoping you may judge them worthy of a place in your Magazine.

Mutual misunderstanding or misinterpretation of terms has been the cause of many a great dispute. And one seldom witnesses a discussion in which the main power of the disputants is not wasted in attempts to refute what has never been advanced, or to establish what has never been questioned. The most important terms employed in the dispute receive different meanings from every person; and some, indeed, are endowed with several distinct significations by the same individual. It is of the greatest moment, therefore, when a weighty doctrine is to be taught, that the words in which it is expressed should be defined with strict precision, and employed with careful integrity. To set forth the exact meaning of the word "force" is absolutely necessary, in order to convey any idea of the subject which heads my present letter. Mathematical writers on Mechanics define "force" to be "the immediate agent which changes, or tends to change, a body's state of rest or motion." After discussing in a somewhat metaphysical manner the terms cause and effect, which have a direct relation to the ideas of force and motion, Mr. Grove says:—

"The position which I seek to establish in this essay is, that the various affections of matter which constitute the main objects of experimental physics, viz., heat, light, electricity, magnetism, chemical affinity, and motion, are all correlative, or have a reciprocal dependence; that neither, taken abstractedly, can be said to be the essential cause of the others, but that either may produce, or be convertible into any of the others: thus heat may mediately or immediately produce electricity, electricity may produce heat; and so of the rest, each merging itself as the force it produces becomes developed: and that the same must hold good of other forces, it being an irresistible inference from observed phenomena that a force cannot originate otherwise than by devolution from some pre-existing force or forces."

Again:—

"The term force, although used in very different senses by different authors, may be defined as that which produces or resists motion. Although strongly inclined to believe that the other affections of matter, which I have above named, are, and will ultimately be resolved into modes of motion, many arguments for which will be given in subsequent parts of this essay, it would be going too far at present to assume their identity with it; I therefore use the term force in reference to them, as meaning that active principle inseparable from matter which is supposed to induce its various changes."

It does not require much consideration to perceive that chemical affinity and magnetism are forces, according to the definition which I have given above. And a very slight relaxation of its rigour, will make it include heat, light, and electricity, which are certainly causes, if they be not immediate causes of change of motion. There is not much to object to in Mr. Grove's definition of forces, but, as we shall see, he does not confine the term to any single idea. It is sometimes used, according to the definition, to indicate the cause of motion, sometimes the motion itself—and this occasions serious confusion. Whether Mr. Grove is unconscious of this disorder I cannot say. I think, however, he underrates its importance. In direct relation to this subject, he makes the following excellent remarks, which, though somewhat lengthy, are well worthy of the space they will occupy:—

"The word force, and the idea it aims at expressing, might be objected to by the purely physical philosopher on similar grounds to those which apply to the word cause, as it represents a subtle mental conception, and not a sensuous perception or phenomenon. The objection would take something of this form. If the string of a bent bow be cut, the bow will straighten itself; we thence say there is an elastic *force* in the bow which straightens it; but if we applied our expressions to the experiment alone, the use of the term force would be superfluous, and would not *add* to our knowledge on the subject. All the information which our minds could get would be as sufficiently obtained from the expression, when the string is cut, the bow becomes straight, as from the expression, the bow becomes straight from its elastic force. Do we know more of the phenomenon, viewed without reference to other phenomena, by saying it is produced by force? Certainly not. All we know or see is the effect; we do not see force—we see motion or moving matter.

"If now we take a piece of caoutchouc and stretch it, when released it returns to its original length. Here, though the subject-matter is very different, we see some analogy in the effect or phenomenon to that of the strung bow. If, again, we suspend an apple by a string, cut the string, the apple falls. Here, though it is less striking, there is still an analogy to the string and caoutchouc.

"Now, when the word force is employed as comprehending these three different phenomena, we find some use in the term, not by its explaining or rendering more intelligible the *modus agendi* of matter, but as conveying to the mind something which is alike in the three phenomena, however distinct they may be in other respects; the word becomes an abstract or generalized expression, and regarded in this light is of high utility. Although I have given only three examples, it is obvious that the term would equally apply to 300 or 3,000 examples.

"But it will be said, the term force is used, not as expressing the effect, but as that which produces the effect. This is true, and in this, its ordinary sense, I shall use it in these pages. But though the term has a potential meaning, to depart from which would render language unintelligible, we must guard against supposing that we know essentially more of the phenomena by saying they are produced by something, which something is only a word derived from the constancy and similarity of the phenomena we seek to explain by it. The relations of the phenomena to which the terms force or forces are applied, give us real knowledge; these relations may be called relations of forces; our knowledge of them is not thereby lessened, and the convenience of expression is greatly increased, but the separate phenomena are not more intimately known; no further insight into why the apple falls is acquired by saying it is forced to fall, or it falls by the force of gravitation; by the latter expression we are enabled to relate it most usefully to other phenomena, but we still know no more of the particular phenomenon than that under certain circumstances the apple does fall.

"In the above illustrations, force has been treated as the producer of motion, in which case the evidence of the force is the motion produced; thus we estimate the force used to project the cannon ball in terms of the mass of matter projected, and the velocity with which it is projected. The evidence of force when the term is applied to resistance to motion is of a somewhat different character; the matter resisting is molecularly affected, and has its structure more or less changed; thus a strip of caoutchouc to which a weight is suspended is elongated, and its molecules are displaced as compared with their position when unaffected by the gravitating force. So a piece of glass bent by an appended weight has its whole structure changed; this internal change is made evident by transmitting through it a ray of polarised light. A relation thus becomes established between the molecular state of bodies, and the external forces or motion of masses. Every particle of the caoutchouc or glass must be acting and contributing to resist or arrest the motion of the mass of matter appended to it.

"It is difficult, in such cases, not to recognise a reality in force. We need some word to express this state of tension; we know that it produces an effect, though the effect be negative in character, although in this effort of inanimate matter we can no more trace the mode of action to its ultimate elements than we can follow out the connection of our own muscles with the volition which calls them into action, we are experimentally convinced that matter changes its state by the agency of other matter; and this agency we call force."

Although these, as I have already said, are very excellent and wise remarks, yet they may perhaps tend to mislead the mind of the reader, if he be not careful to remember that what is here justly said of force applies equally to all our ideas. Take, for example, the subject of geometry, with which our most exact perceptions are connected. The geometer will search his mind in vain for an idea of absolute magnitude, whether of distance, of surface, or of volume. When we say that the diameter of the earth is nearly eight thousand miles, this is but a statement of a relation. And we know no more of distances taken separately by saying that any given line is ten feet or ten miles long. With this idea of distance, our notions of velocity and motion are intimately connected. And if we examine these metaphysically, I think we shall find them no more definite—certainly no more absolute—than our idea of force. It is well to sift our ideas on all subjects in the most rigourous manner possible; but in settling the relative value of any two, we must subject them both to the same scrutiny. And if this be fulfilled, there is on my mind no doubt whatever, that our idea of what mathematicians term force or pressure will be found as worthy of a place amongst our primary perceptions, as that of distance, area, volume, matter, motion. Take any proposition involving these terms, and endeavour to determine in how far it is a mere *façon de parler*, and in how far it is the expression of real knowledge? how much is arbitrary mental assumption, and how much objective truth? and you will find yourself engaged in a most difficult, if not an impossible task. Under such an inquiry, I do not see that our notion of force would be found relatively more fugitive, or more subtle than the others. Moreover, it appears to me that Mr. Grove has done this idea some little injustice, in giving his first and best notice to forces producing motion, and almost overlooking static forces, introducing them last, and recognising them only by the molecular changes which they work on the bodies subjected to their action. I am satisfied that the method of treating statics first as the more simple relations of force—a method adopted by mathematical writers on mechanics—is by far the more just and natural proceeding. Confining the attention to the observation, by the eye, of bodies in motion, we are apt to say with Mr. Grove, "We do not see force—we see motion, or moving matter." But it must be remembered that we have more senses than the sense of sight—that ideas enter the mind by other avenues besides the eye. There are the senses of smell, taste, touch, hearing. And many things which are hidden from the eye, are yet not concealed from the mind. An idea revealed to us by feeling, is not of less authority, not less worthy of trust, than if ushered to our

Digitized by Google

knowledge by the hearing or the sight. Force we cannot expect to see, nor hear, nor taste. But do we not know it from feeling as intimately as we know by the eye the countenance of a friend, and by the ear recognise his voice? Every man, whether loaded porter or idle voluptuary, reclining on his couch, while he is conscious at all, has a distinct idea of static force, quite apart from its effect of producing motion. And every vender of butter or cheese knows how this force of pressure may be measured with as much accuracy as the surveyor can measure an estate, or the astronomer the distance to the moon. It is at a comparatively advanced stage of physical inquiry that we deduce the existence, direction, and amount of force from the data of their observed effects in changing motion.

If it meet your approval, I shall be glad to lay before your readers a few more observations on this topic next week.*

I am, yours, &c.,

A MECHANIC.

CURRENT EVENTS IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

(COMPILED BY OUR OWN CORRESPONDENT.)

The Holiday on Monday—A Lozenge-making Machine—Disputes in the Glass Trade—Christmas Boxes: their discontinuance—Important Railway arrangements—The Annual Ball of the Great Western Company—Railway Collision—Steam Boiler Explosion Association — Election of Chief Officer — Iron Engine House — New Market Hall at Manchester — Mersey Dock Board: weekly meeting — New Cotton Mill — New Weaving Mill — New Boiler Manufactory—Annual Soirée at Newcastle-on-Tyne—New Town-hall at Alston —The Tyne a Harbour of Refuge—Trying a New Railway Brake—Mining Matters in Bacup, Wakefield, Oldham, and South Staffordshire—An Infant Engine Tender!

THE Manchester, Liverpool, and Leeds Stock Exchanges were all closed on Monday. The black county was no exception to the general rule under which that day was observed as a holiday. In the towns very few shops were opened, and in their vicinity the tall stacks, which commonly are belching forth wreaths of dense smoke, were without this ornamental but unpleasant append age. Here and there a brisk fire on the bank of a new pit told that some sinkers were at work; and at considerable distances apart a handful of men might be seen completing an urgent order of rails or boiler plates. In other respects all was holiday keeping. The stations were thronged during the greater part of the day with pleasure takers desirous of joining in one or other of the many amusements which were offered to them in Birmingham.

A Mr. Chase, of the United States, has succeeded in inventing a machine for making lozenges, and has opened an establishment in Shadwell-street, Birmingham, under the name of Messrs. Chase and Co. The invention works in the most satisfactory manner, and is very remunerative. The machine is very simple and neat, and it fulfils its design in a very rapid and complete manner. A ball of prepared sugar is worked up to the consistency of soft dough, and is rolled out on a board to the thickness of the top of a good-sized fruit pie. It is then laid upon a revolving band, which carries it between a pair of rollers. It is then flattened, and passed through more rollers, until it is spread out to the thickness of a lozenge; it goes again upon the band, and is by it conveyed underneath a quantity of stamps in a straight line, bearing a motto or name, as may be previously directed by order; the paste is then perforated by circular cutters, and clean, glossy lozenges are thrown out with inconceivable rapidity, row after row. It can be worked at almost any speed, and can produce 300 lbs. of sweetmeats an hour. The trade can thus be supplied wholesale with lozenges of all shapes, sizes, and qualities, equal to the best hand-make, and at reduced prices.

The disputes in the glass trade, between the journeymen makers and their employers, which have hitherto been confined to the districts in and around Stourbridge, have at length made themselves felt at Birmingham. On Saturday last the men employed at some six or more of the largest firms in Birmingham received the customary notice of fourteen days either to leave their employment or cease being members of the "Glass Maker's Union." The men appear determined; they have a fund of nearly £4,000, and some of those in work are giving double contributions It is feared that before these disputes can be amicably settled, they will extend to Lancashire. If this should be the case, the consequences are likely to be disastrous to the glass trade generally.

The principal iron-masters of Birmingham have resolved to *discontinue* the practice of giving Christmas-boxes, believing the same to be prejudicial to the interests of the working classes generally.

The treaty by which the recent notorious railway quarrel was put an end to has been followed by an agreement between the three disputing companies, of which the following are the chief points:—Arrangements of a general nature between the three companies as to the traffic from Manchester westward. A line to be made from the Garston station of the Warrington and Stockport Company, or a point near that station, to Edgehill on the Liverpool line of the London and North-Western Company The line of the Warrington and Stockport Company to be extended, for goods purposes, as far, at least, as the Brunswick Dock, Liverpool. The Sheffield Company to have, at Liverpool, and in the offices of the London and North-Western Company, its own clerks both for passenger and goods traffic; and general facilities, upon expressed terms, to be given to that Company and to the Great Western. A bill in Parliament to be promoted jointly by the three Companies to give legal effect to these arrangements.

The annual Ball of the Great Western Railway Widow and Orphans' Fund is to come off on Wednesday next (on this occasion at Oxford) in the Town Hall, under the patronage of the Mayor and Corporation of that city and the Directors of the line. Special trains will start from Paddington and Chester respectively for the accommodation of persons going to the ball from the chief stations between those points.

On Tuesday afternoon an accident occurred near the Hindley Station on the Lancashire and Yorkshire Railway. About the time that the train, which leaves Manchester at 1·20 p.m. was passing the Hindley Station, where it arrived within a few minutes of its usual time, a coal train was being shunted either to or from a siding a few hundred yards on the Wigan side of the station, and at the time the passenger train neared the siding, two of the coal waggons still remained upon its track. With these the passenger train came into collision; but, fortunately, without any very serious consequences resulting.

On Tuesday a monthly meeting of the Association for the Prevention of Steam-boiler Explosions was held in Manchester. From the monthly report of the resigning chief inspector, Mr. R. B. Langridge, we learn that, during the present month, 242 visits have been made (2 of which have been special) and 672 boilers and 504 engines inspected; 9 of these boilers have been examined internally, and 13 have undergone a thorough examination. Diagrams have also been taken from 87 cylinders. Of these boilers, 24 were found in a defective state from the following causes, viz.:—Corrosion of plates, 3 (1 of these dangerous); fractures of plates, 5 (2 of these dangerous); safety valves out of order, 6 (4 of these dangerous); water guages out of order, 7; pressure guages out of order, 3: total, 24. These defects are of an ordinary character, and do not merit further remark. On the same day a special meeting of the Committee of Management of this Association was held for the purpose of electing a gentleman to fill the office of chief inspector to the Association, rendered vacant by the resignation of Mr. Longridge. There were 81 applicants for the office, from whom, at the first revision, 23 candidates had been selected. These were subsequently reduced to ten, and ultimately seven. of these Mr. H. W. Harman, C.E., North Fleet, Kent, was elected.

Mr. Harman, the successful candidate, was originally a pupil with Messrs. Maudslay, Sons, and Field, of Lambeth, and was subsequently engaged by the Great Western Steamship Company at Bristol, and took an active part in the construction and completion of the Great Britain steamship. Since the year 1845 he has had the management of the Steam Factory at North Fleet Dockyard, Kent.

Messrs. E. T. Bellhouse and Co., of Manchester, exhibited in that city a large iron engine house that they have constructed for exportation to Santiago, The "building" will cover a space of 24,000 square feet, forming a regular polygon of 48 sides, whose diameter is 171ft. The company partook of lunch in a large pavilion within the building. Many gentlemen representing the leading firms engaged in the iron trade attended, and also, Mr. Masenlli and Mr. T. S. Pakenham, from Chili. The latter gentlemen (the engineer appointed by the South Chili Railway Company) took the chair. In the evening the men in connection with Messrs. Bellhouse and Co.'s works were treated to an entertainment.

A new market has just been opened in Manchester. It nearly occupies the site of the old butchers' market, has four fronts, the principal of which are to Goadsby-street (between the new building and Smithfield Market), and to Swan-street. The area of the site is 108 feet by 98 feet; the interior area measures 77 feet by 60 feet, and the height is 44 feet. The building is of Yorkshire pierrepoint stone, with summit stone ashlar dressings.

At the usual weekly meeting in Liverpool, on Tuesday, of the Mersey Dock Board, the Committee recommended that £306 be paid to Messrs. Rankin, Gilmour, and Company, as compensation for damage sustained by the vessel the *Marchmont*, on the 7th October, in the Canada Dock; and £3 15s. to Messrs. Bramley Moore and Co. for damage sustained by the *Doctor Kane* on the same occasion. It was explained that the damage arose from the breaking of a ring, which was made of defective metal, and the vessels getting adrift in consequence. The committee also recommend, that two travelling cranes, for the purpose of loading carts, &c., should be placed under the shed of the North Quay of the Victoria Dock at a cost of £500. The proceedings and recommendation were confirmed.

Mr. Alderman Harwood, corn merchant, has commenced the foundations of a new cotton mill, in Great Lever, immediately adjacent to the borough of Bolton. It is to be a four-storey building, calculated for 40,000 spindles, and a shed for the preparatory process of cotton spinning.

From Bacup we learn that the new mill of Messrs. Joshua Hoyle and Sons has commenced running. A building, formerly used as a foundry, has undergone alterations transforming it into a weaving shed. The mill of Messrs. James Smith and Sons has been enlarged. A boiler manufactory has been recently established.

At Newcastle-upon-Tyne, on Tuesday evening, the annual *soirée* of the Mechanics' Institute of that town was held under the presidency of the Mayor, who was supported by a company numbering nearly 500. A large proportion of the 500 members of the institute are mechanics—an exception to the general rule—and there are 9,000 volumes in the library. There are more members on the books now than for four years past.

At Alston, near Newcastle, a new town hall was opened with much spirit on Tuesday. The building is situated on the rising ground near the

* We have been compelled to leave much of our excellent correspondent's present letter standing until next week.—EDS. M. M.

Digitized by Google

Vicarage of Alston. It is mediæval in style, and, with its clock tower, gables, and pinnacles, is a conspicuous object from many points of view. The tower forms the principal entrance to the building. The various works have been executed in the most substantial and satisfactory manner by Mr. Thomas March, the contractor, from the designs and under the superintendence of Mr. A. B. Higham, of Newcastle.

Three documents of considerable interest to the maritime community were laid on the table at the meeting of the Tyne Improvement Commissioners on Thursday last, having been printed for the use of that body. One is the memorial of the Tyne Improvement Commissioners to the Royal Commissioners on Harbours of Refuge; another the report of Mr. Walker on the Tyne as a Harbour of Refuge; and the other is a report by Mr. T. J. Taylor, of Earsdon, containing his remarks on the reports and plans of Mr. Walker for the extension of the piers.

The newly-invented brake of M. Guerin, of France, was tried on the Shields line, the other day, with great success.

In mining matters we note that the colliers employed in the neighbourhood of Bacup, on the Spotland side, have all obtained an advance of 8d. per day.——The workmen employed by Messrs. Patchett, Woodhead, and Hunter, at the Manor Colliery, Westgate Common, Wakefield, commenced work, on Friday last, at the terms paid previous to the late attempted reduction of first 15 and then 7½ per cent.——Mr. Oldham's men went in on Tuesday morning at a rise of 1d. in the shilling, The men struck work on the 29th July last against a reduction of 2d. in the shilling, and after they had been out ten weeks and two days, they were informed that they might commence work at the old price; but that they refused to do, and demanded an advance of 2d. in the shilling, that amount having been obtained by some of the miners in the district. On the 9th instant an offer of an advance of 1d. in the shilling was offered, but up to Tuesday was rejected by the great body of the men. It will be thus seen that the strike is at an end in the Ashton district. The Dunkinfield Coal Company's men, in Dunkenfield, are still out, but the other large company is at full work.——The South Staffordshire men are now at work at a drop of 1s. a-day.——At Willenhall, in South Staffordshire, last Monday, a child of eleven was shown to be the person in charge of an engine at a colliery, the property of Mr. S. Frost, who said that he (the child), "had been an engineman from his cradle!" To the hands of this child the lives of twenty colliers were entrusted. His wages were 1s. 3d. a-day, and he had been charged by his master with unlawfully detaining a key. The magistrate remarked that the defendant seemed too young for the situation, and that a boy of that age could not be fit to cope with any emergency that might arise, and was more likely to run away than to act with the requisite nerve.

NOTES FROM THE EASTERN COUNTIES.

(FROM OUR OWN CORRESPONDENT.)

Miniature Steam Engine — Clearing the River between Farnham and Mildenhall — London, Dunmow, and Bury St. Edmund's Railway.— Fowler's Steam Plough —Settlement of a Dispute—Remuneration of an Engineer.

A BOY named Charles Lack, residing at Fen End, Willingham, Cambridgeshire, has constructed a miniature steam-engine displaying much ingenuity. The weight of the engine, exclusive of the boiler, is only 7½ oz., and a high speed has been attained by it, while the steam has been got up in three minutes. The ingenious little toy has been constructed by the lad after the regular work of the day has been disposed of.——An effort is being made to re-open the navigation between King's Lynn and Bury St. Edmund's. A large number of men are now engaged in cleaning out the bed of the river between Farnham and Mildenhall; and it is thought that the sewerage of Bury St. Edmund's (which has for some time been a vexed question) is likely to be advanced by what is being done, as it is not probable that when the river has been improved, the proprietors of the navigation will allow it to be silted up again with the outpourings of the town. ——The most important railway project in the Eastern counties which will be brought before Parliament in the ensuing session is the London, Dunmow, and Bury St. Edmund's. This line is nearly 70 miles in length, and, if carried out, will afford a most direct route to the metropolis from Norfolk, Suffolk, and Essex. The undertaking will, of course, be stoutly opposed by the Eastern Counties Company. Mr. T. B. Grantham is engineer.——Fowler's steam-ploughing apparatus was put in operation a day or two since on the Lynford estate, in Norfolk. A number of persons interested in the solution of the steam-ploughing problem assembled on the occasion, and the result of the trial is favourably spoken of. ——A long-pending dispute between Messrs. H. and M. Grissell and the Great Yarmouth Haven and Pier Commissioners has just been disposed of by arbitration. The dispute referred to the amount due to Messrs. Grissell on the balance of their account as contractors for a new bridge, erected at a very considerable expenditure over the Yare, at Great Yarmouth. The sum of £2,769 5s. 4d. has been awarded to Messrs. Grissell by the arbitrators, Mr. J. Fowler, C.E., Mr. J.-R. McClean, C.E., and Mr. I. K. Brunel, C.E. (umpire). The original contract was, £23,734 10s. The Commissioners paid, on account of the contract and extras, £25,584 1s. 10d., and Messrs. Grissell claimed £32,334 5s. 7d. The amount struck off by the arbitrators was, therefore, £3,980 18s. 9d.——The Great Yarmouth Town Council authorised, some time since, an expenditure of 200 guineas, to support the claims of the port before the committee appointed on the harbour of refuge question. The amount expended, however, was £244, Mr. Walker, C.E, charging £200 for his services. Some grumbling took place in the council when the bill was presented. it being urged that the charges of the engineer were excessive. On the other hand, it was contended that Mr. Walker was the Admiralty engineer, that his influence was exceedingly valuable, and that, consequently, his charges were not too high. An attempt to reduce the expenditure to the amount originally voted, was defeated by a large majority, and the account was ordered to be paid in full.

METAL AND COAL TRADES, &c.

(FROM OUR OWN CORRESPONDENT.)

Preliminary Meeting of Ironmasters yesterday— Condition of the South Staffordshire and East Worcestershire Coal and Iron Trades—Glasgow Pig Iron Market—Northumberland, Durham, and Derbyshire; with North and South Wales districts—Liverpool Pig Iron Market—The Hardware Trades of Birmingham, Wolverhampton, and Sheffield—Copper and Tin— Board of Trade Returns.

The preliminary meeting of the Iron Masters was held at Dudley on Thursday (yesterday). Although some few makers desired an increase of 10s., yet there was no alteration made in the previously existing rates, viz., bars, £7 10s.; hoops, £8 10s.; and sheets, £9 10s. The trade generally still maintained a favourable position, and there is every indication of a steady progress. There are more inquiries, and those makers who have been selling under the trade prices are now declining orders except at improved rates. There seems to be no doubt that the coming year will be one of considerable prosperity. Pig iron continues firm. It is very probable that before long the producers will be able to realise a fair and legitimate price, which has scarcely been the case during the last year.

The coal trade of South Staffordshire and East Worcestershire and prices are firmly maintained, and although a large quantity is being imported into the districts from a distance, it does not materially affect the native produce. Prices have an upward tendency. The strike of colliers and miners there is at an end, and the districts have assumed their wonted quietude. The colliers and miners are for the most part fully occupied.

The following are the quotations of the Glasgow pig iron market on Tuesday last:—No. 1, 52s. 6d. to 52s. 9d.; mixed Nos. warrants, 54s. to 54s. 3d.; and also ditto makers' iron, No. 3., 52s. 6d. to 52s. 9d. Shipped this week, 6,100 tons; corresponding week last year, 7,050 tons.

The coal and iron trades in Northumberland and Durham are represented as somewhat depressed, with certain exceptions, depending on the nature of the coal, &c., produced. At those collieries where only gas coal is produced, there is at present a greater demand than can be supplied.

In Derbyshire, and the adjacent districts, the coal trade is reported to be exceedingly good, prices being very well maintained. It is expected that the Duke of Newcastle's new colliery at Worksop will be down in the spring of next year upwards of 560 yards to the top hard coal of Derbyshire or Barnsley bed.

In the South Wales district the condition of the iron trade is still reported as favourable, the arrival of several fresh orders having given renewed confidence to the masters. Although there is partial slackness in particular localities, yet at the principal works there is general briskness. The chief foreign demand is from France and Russia, but the new lines of railway, now in course of construction in America, require a large and constant supply of rails, and no small portion of the orders for that supply find their way into the South Wales district. Amongst the establishments largely engaged in executing orders of this description, are the Tredegar Works, and those at Ebbw Vale, Nant-y-Glo, and Blaina. The coal trade in the district is not particularly brisk, but there is a somewhat steady demand. In every respect, however, the trade of South Wales is in a much more prosperous state than was the case at the corresponding period of last year.

In respect of North Wales it may be said that the coal trade remains tolerably active in the Wresham district. The iron trade also in that district is flourishing. In the neighbourhood of Ruabon, matters are decidedly looking up, and confident anticipations are formed of a good winter trade. The business in coal is very brisk, the men are fully employed, and are earning good wages.

At Acrefair some excellent orders for iron have been received, which, it is anticipated, will keep those extensive works in active operation for some time to come. At Rhosymedre the freestone trade is prosperous and active.

In the pig iron market at Liverpool on Monday last, business was done at 54s. cash, and the market closed with sellers at 54s. 3d. cash, and buyers at that price one month (open).

In Birmingham the manufacturing trades have evinced a quietude generally prevalent at the close of the year. During the last eight weeks, however, there has been tolerably full employment, and many of the large manufacturers in some of the most important branches will commence the new year with an encouraging number of orders on hand.

The trade of Wolverhampton continues in a state of quiet prosperity. In no branches can we learn that there are any very large orders in hand; but this, at the present season, cannot be expected. The hollow-ware trade, in which there has been the greatest depression, is beginning to assume a healthier aspect, although some time must necessarily elapse before it resumes its former condition.

At Sheffield, the general trade of the town and neighbourhood is also quiet. In most instances, however, the men have made full time. Merchants and manufacturers look with anxiety to the commencement of the new year, fearing, as they do, that they will be tramelled by the threatened restrictive policy of certain foreign nations, that are now their customers. For instance, the American tariff is soon to be raised,

Digitized by Google

on an average, probably, of five per cent. The Canadian tariff has also been recently revised, and assimilated to American rates. The Americans are greatly increasing their manufacture of hardware goods—particularly shovels, pick-axes, and axes—which they send in large quantities to various British colonies. One house alone is said to sell shovels to the amount of £250,000 a year.

The markets in copper and tin have remained without much, if any, alteration in the past week, except a growing opinion that they will go higher before they recede again. The advance of £5 in copper has not checked the general trades dependent upon that metal for their raw material. On the contrary, they exhibit more activity this week than last. At the same time, there is little doubt but the advance is in part speculative, and due to the low price of money. Sufficient tin for even immediate necessities can be had only with difficulty, even at the last advance. The metal is unquestionably very scarce, and a further rise is regarded as on the eve of taking place.

The Board of Trade returns for November, and the eleven months ending with that date, furnish us with information on the comparative exports in the month of November in the three undermentioned years.

METALS.	1856.	1857.	1858.
Pig Iron	£119,802	£108,919	£ 59,537
Bar and Rod Iron	454,733	388,892	395,436
Iron Wire	23,591	31,962	16,447
Cast Iron	79,216	60,429	49,095
Wrought Iron	329,410	321,454	245,494
Steel	70,966	39,199	45,712
Copper, unwrought	50,246	82,806	81,822
Copper and Yellow Metal sheathing	159,720	108,338	141,305
Wrought Copper	15,261	51,350	25,690
Brass	14,415	15,135	18,146
Lead	40,899	25,613	36,959
Tin, unwrought	17,555	17,381	10,941
Tin Plates	136,260	53,592	100,874
MACHINERY.			
Steam Engines	101,516	44,649	45,044
Other kinds	172,249	250,262	150,403
Hardware and Cutlery	371,564	315,092	291,531

The pig iron exports for the eleven months show a falling off from £1,554,577 to £1,056,455, or nearly one-third; and bar iron, though the trade was better in November than at the corresponding period of last year, from £5,924,511 to £4,908,289, notwithstanding a considerable increase in the exports to India. Wrought iron was affected to the same extent, showing a decline from £3,767,781 to £3,084,012, though in this trade also, there was an increased exportation to the British possessions in the East.

There was an increase in the exports of hardware and cutlery to the United States, and likewise to the Hanse Towns; but the entire trade of the eleven months was only £2,986,710, against £3,740,743. The slight increase in steam engines was referable to the Russian demand, which has been very great throughout the year, exceeding that of any other country. This is the only branch of the machine trade which compares favourably with last year. There was however, an increased exportation of all kinds of machinery to Russia, France, and Australia.

The copper, brass, and yellow metal trades have not been near so much depressed; and the same may be said also of lead and tin manufactures. The tin plate exports declined from £1,462,217 to £1,258,664, but the Australian demand improved last month, and there are prospects of further change for the better in other directions.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

RAILS.—4,000 tons, for the London and North-Western. Specifications, &c., from Mr. C. E. Stewart, Secretary, Euston Station.

SLEEPERS.—100,000 creosoted sleepers, for East India Railway, as per specifications at Alderman's, Walbrook. Tenders on or before 12 at noon, January 4.

WATER-WORKS PIPES.—156 tons, for the Dundee Water-works. Specifications, offices, Dundee Water-works.

GAS PIPES.—5,000 16-inch socket pipes, for the Birmingham and Staffordshire Gas Light Company, to be cast vertically, and weighing 332 lbs. per yard, delivered at the Trench-side, on the road from Wednesbury to Walsall. The tenders to be sent in on or before Monday, the 3rd day of January, addressed to the secretary of the company.

SETTING-UP OF SMALL ARMS.—War-office.—Applications from persons desirous of tendering for future supplies, or setting-up of small arms, invited by the Secretary of State for War.

NORTHERN LIGHTHOUSES. — Construction and fitting-up, at their respective sites, of lanthorns, &c., for certain lighthouses now in progress, according to plans by Messrs. D. and T. Stevenson, 84, Church-street, Edinburgh. Tenders on or before January 10.

COALS.—1,000 tons of gas coal, by the Improvement Commissioners of Walsall, to be delivered in carts at their gas works, at the rate of about 40 tons per week. It is to be all large coal, and the weight per ton is to be 2,640 pounds. Tenders on or before January 6.——5,000 tons suitable to locomotive burning, on Shrewsbury and Hereford, to be delivered in regular quantities of 120 tons weekly, at their works, Shrewsbury, or Barr's-court engine-shed, Hereford. Tenders to Mr. E. Jeffreys, Colehamworks, Shrewsbury, on or before January 5.——3,500 tons of South Wales, fit for service of Her Majesty's steam vessels, to be delivered in Jamaica. Conditions, &c., at Somerset-place. Attendance before the Commissioners, or by duly qualified agents, 2 o'clock, January 4.

ROADS.—The Corporation of Dublin invite tenders for the maintenance and repair of the macadamised streets and gravelled footways of that city for three years. 45,000 tons of stone to be laid in all. The contract may be taken in whole or part, according to the requirements of the city engineer.

SCAVENGERING.—For the Crown Estates Paving Commissioners, during one year, January 5. Forms at the office of Mr. Francis Adams, clerk to the Commissioners, 1 Whitehall. ——The Dublin Corporation are prepared to receive tenders to February 4, for the scavengering, cleansing, and watering of Dublin during three years, beginning with May next, agreeably to printed Specifications prepared by the city engineer.

RUSHOLME PUBLIC HALL AND LIBRARY.—Tenders to be sent in on or before January 10. Particulars from Mr. W. W. Whittaker, architect, 32 St. Ann-street, Rusholme.

BARRACKS AT PORTSMOUTH.—War Department, Pall Mall, January 24.—Plans at Royal Engineer's Office, Portsmouth, from 3rd to 22nd January.

SCHOOLS, LINCOLNSHIRE.—Two schoolrooms and master's house, Sutton, St. James's, Lincolnshire, January 15.—Plans at the office of Mr. J. P. Sturton, solicitor, Holbeach.

COUNTY GAOL, WORCESTER.—New wings, &c, January 15. Plans at the offices of Mr. Henry Rowe, county surveyor, 17 Foregate-street, Worcester.

COTTON WASTE AND OIL.—By the London and South-Western Railway Company, 20 tons of cotton waste, and 5,000 tons of best burning oil. Forms of tender to be had from the storekeeper at the Nine Elms Station. Tenders to be delivered not later than January 3.

LOCKS, GONGS, &c.—For the new wing of Leicester Gaol. Mr. E. Stevens, borough surveyor, Silver-street, Leicester, on January 15.

PARISH CHURCH SPIRE.—At Ince, in Straurear. Plans, &c., in the hands of Mr. Guthrie, Rephad, Straurear. Estimates before January 14.

LIGNUM VITÆ.—Seventy tons, being 60 St. Domingo and 10 White Bahama, at Her Majesty's Dockyard, Portsmouth. Date for tender, January 11.

ARCHITECTS' COMPETITIONS.—Designs for the Manchester Assize Courts, by March 1. Particulars from Mr. Frederick C. Hulton, 37 New Bailey-street, Salford. Premiums of 250*l.*, 150*l.*, and 100*l.* respectively.——Town-hall, Council-house, Police-office, and Market-houses for the borough of Folkstone. Plans on a scale of 8 feet to the inch, by January 5, to Mr. R. T. Brockman, town clerk, who, for 2*s.* 6*d.*, will forward particulars. Premiums, 30*l.* and 10*l.* Estimate not to exceed 3,000*l.*——New chapel, Aberystwith, not to exceed 1,500*l.* Mr. John Matthews, land surveyor, Aberystwith, will receive the plans up to January 22. 5*l.* prize.

GAS MANAGER.—The Newry Gas Consumers' Company (Limited) are in want of a working manager. Applications to Mr. Charles Lawson, Newry.

IRON WORKS MANAGER.—To superintend the erection of iron works, and undertake their management, for the manufacture of a superior description of iron. H. H., 12 Stoke-orchard, Caledonia-road, Holloway, N.

PROVISIONAL PROTECTIONS.

Dated October 22, 1858.

2360. E. Whitehall, of Nottingham. Certain improvements in machinery for the manufacture of cap fronts.

Dated November 13, 1858.

2548. J. Taylor, of Birkenhead, Engineer. Improvements in portable steam engines.

Dated November 17, 1858.

2588. M. Scott, of Hyde-park-gardens. Improvements in the construction of breakwaters, parts of which are applicable in making other structures.

Dated November 19, 1858.

2626. J. H. Johnson, of Lincoln's-Inn-fields. Improvements in the construction of electric telegraph cables or conductors.—A communication from H. J. Rogers, of Baltimore U.S.

Dated November 27, 1858.

2696. J. Ramsbottom, of Accrington, Engineer. Improvements in machinery or apparatus applicable to water meters, and to indicating and regulating the flow and pressure of fluids generally, and in obtaining motive power from the same.

Dated December 3, 1858.

2762. T. Bailey, of Birmingham, Gun Maker. A mechanical movement applicable to loading fire-arms, and other purposes.

2764. G. E. Noone, at Newington Butts, Engineer. Certain improvements in machinery for generating gas from coal.

2768. C. F. Vasserot, of Essex-st., Strand. An improved apparatus for ventilating mines, or other similar purposes. A communication from M. Welter, and G. Bohringer.

2770. H. Bevan, of Shrewsbury, Accountant. New or improved machines for effecting or facilitating arithmatical operations.

Dated Decembe 4, 1858.

2772. R. Legg, of Ashby-st., Clerkenwell, Millwright. A machine for combining the operation of compressing and cutting tobacco during the process of manufacture.

2774. J. B. Fisher and J. Fisher, of Stourbridge, Worcester, Fire Brick Manufacturers, and J. Bird, Jun., of Kingswinford, Stafford, Agent. An improvement in the doors and dampers of furnaces, and other places where intense heat has to be resisted.

2776. E. A. Servier, of Paris, Engineer. Improvements in pressure and fluid level indicators.

2778. A. Smith, J. Townsend, and E. W. Williams, of Birmingham, Manufacturers. An improvement or improvements in breech-loading fire-arms.

2780. J. Turner, of Queen's-road, Dalston. Improvements in the construction of chairs.

2782. J. L. Norton, of Belle Sauvage-yard, Ludgate hill. Improvements in machines for stretching and drying fabrics and in drying wool and other fibres.

2784. W. E. Newton, of Chancery-lane. Certain improvements in grain and grass harvesting machines.—A communication.

2786. T. R. Harding, of Leeds, Hackle Pin Maker. Improvements in combs, gills, hackles, and similar implements used in silk, wool, and flax machinery, and in the method of making the same.

Dated December 8, 1858.

2811. C. de Cappot, and A. Jarriant, of Neuilly-sur-Seine, France, Civil Engineers. A new hydraulic counter.

2831. M. Henry, of Fleet-st. Improvements in twisting fibrous materials, and in machinery or apparatus employed therein.—A communication from Messrs. Durand and Pradel.

2815. A. Lamb and W. A. Summers, of Southampton, Engineers. Improved arrangements of apparatus for superheating steam.

2817. C. M. Westmacot, of Litchurch, near Derby. Improvements in the permanent way of railways.

Dated December 9, 1858.

2819. R. L. Burrowes, of St. Helen's, Lancaster, Professor of Music, and J. Knowles, Jun., of the same place, Mine Surveyor. Certain improvements in the construction of piano-fortes and organs.

2821. H. Maudsley, of Lambeth, Civil Engineer. Improved glass, and other vitreous vessels.

2823. H. Bell, of Belfast. Improvements in musical instruments.

Digitized by Google

2825. J. Elder, of Glasgow, Engineer. Improvements in paddle-wheels

2827. T. Allen, of Clifton, Bristol, Ironmonger. Improvements in folding bedsteads.

2829. H. Wilson, of Norton, Durham, Brass Finisher. Improvements in the construction of pumps.

2831. B. Lauth, of Trafalgar-square, Mechanician. An improved mode of manufacturing rods and shafts.

Dated December 10, 1858.

2833. J. Lightfoot, of Accrington, Calico Printer. Improvements in printing or staining yarns, fabrics, or fibrous substances, and in the manufacture of certain compounds for that purpose.

2835. A. Barclay, of Kilmarnock, Engineer. Improvements in electric, magnetic, and electro-magnetic telegraph ropes or conductors.

2837. C. Hodgson, of Ballard Rathdrum, Wicklow. Improvements in the manufacture of fuel from peat, and and in apparatus employed therein, part of which is also applicable to the moulding of bricks, tiles, and other plastic materials.

2839. G. F. Wilson, of Vauxhall. Improvements in the manufacture of lubricating oils.

Dated December 11, 1858.

2841. W. F. Hall and T. Dutson, of Birmingham, Button Makers. Certain improvements in fancy buttons for ladies' and gentlemen's wear.

2843. S. Dudgeon, of Sheffield. An improved gas regulator.

2845. P. Robertson of Sun-court, Cornhill. Improvements in shuttles.—A communication.

2847. M. Schaffner, of Eisenach, Civil Engineer. Improvements in smelting zinc ores, and in furnaces employed for this purpose.

2849. A. Rollason, of Birmingham, Chemist. For improvements in the manufacture of waterproof tissues, and in applying such water-proof material to woven fabrics, and manufactured fibrous goods.

NOTE.—Specifications will be forwarded by post on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table:—

STEAM ENGINES, &c.,	954, 955.
BOILERS AND THEIR FURNACES,	956, 959.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c.,	960.
SHIPS AND BOATS, including their fittings.	*None.*
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines,	958, 964.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals,	951.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c.,	957, 961, 963, 965.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c.	*None.*
LIGHTING, HEATING, AND VENTILATING.	*None.*
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.,	952.
METALS, including apparatus for their manufacture,	950.
CHEMISTRY AND PHOTOGRAPHY.	*None.*
ELECTRICAL APPARATUS.	*None.*
WARFARE,	953.
LETTER PRESS PRINTING &c.,	*None.*
MISCELLANEOUS,	960, 962, 963.

950. J. H. JOHNSON. *Improvements in furnaces for the melting and reduction of steel, copper, zinc, and other metals.* (A communication.) Dated April 28, 1858.

These consist in the introduction of heated air by tubes set in masonary, which act as blow-pipes upon the flame as it enters the melting furnace. The furnaces surround a central furnace which heats the series. It is fed with fuel from above, and is supplied with a hot blast, which spreads the flame into the melting furnaces containing the retorts or crucibles filled with the ores or metals. Other parts are included. *Patent abandoned.*

951. J. MARTIN. *Improvements in machinery or apparatus for reducing, cutting, or pulping roots and other substances.* Dated April 29, 1858.

Here the substances to be reduced are operated upon by knives, cutters, or reducers placed inside a revolving hollow cylinder. *Patent completed.*

952. S. BARTLETT. *Improvements in machinery for forming gutta percha soles and uniting them to the upper leather of boots or shoes.* (A communication.) Dated April 29, 1858.

Here two thick metal plates are used, of nearly the same shape as the sole, and connected by bolts and nuts. To the upper one is fixed the covering of the shoe on its last, and to the lower one is attached a hollow metallic mould having internally the shape of the sole and heel, which is filled with semi-fluid gutta-percha spreading it over the whole surface. Heat is applied to the mould, which is immediately screwed up tight against the under side of the last, and allowed to cool. *Patent completed.*

953. E. SIMONS. *Improvements in ordnance.* Dated April 29, 1858.

This is particularly applicable to small guns. The inventor constructs two (or more) cannons together, the breach end of one being joined to the breach end of the other. The double gun is supported upon an axis passing through the breach. The lower end of the axis carries a sphere enclosed in a slotted hollow sphere. The axis may thus be placed vertically or depressed. The hollow sphere is fixed on the gun carriage. *Patent abandoned.*

954. A. M. PERKINS. *Improvements in high-pressure steam-engines.* Dated April 29, 1858.

This consists in a method of condensing the steam from such engines, that the boiler may have the condensed water returned at a high temperature. The steam is passed into a case which receives one of the ends of each of a number of small pipes open to the atmosphere at their other ends. Within these the steam condensed (the tubes being long,) runs back into the case, and thence into a pump, by which it is returned to the boiler. For passing air amongst the pipes, the patentee encloses them in a chest, open at one end to the air, and at the other end in connexion with the ash pit of the furnace. *Patent completed.*

955. C. LAWRENCE. *Improvements in steam-engines.* Dated April 29, 1858.

This relates to combinations of parts applied to steam-engines, by which motion is given to the piston in one direction, and to the cylinder in the opposite direction. *Patent completed.*

956. R. JOHANNY. *Improvements in the construction of furnaces.* Dated April 29, 1858.

This consists principally in the use of a closed fire-hearth, and of certain fire tubes and air tubes. *Patent completed.*

957. W. SMITH, *Improvements in spinning machinery,* (A communication) Dated April 29, 1858.

This consists in the radical suppression of drums or cylinders in spinning frames, whether driving their spindles by bands or tapes. The patentee claims, 1st. The adaptation of a continuous band employed in connexion with pressing rollers for transmitting motion to a series of spindles. 2nd. The combination of a single endless belt, with pressing rollers, and directing rollers when employed for rotating more than two spindles in a spinning machine. 3rd. Several methods of operating the whole of the spindles (or in very long frames any set and section consisting of several spindles) contained within a spinning frame by a single continuous band applied and worked as described. *Patent completed.*

958. W. SMITH. *Improvements in steam ploughs.* (A communications.) Dated April 29, 1858.

This relates to a gang of ploughs driven in either direction by steam power. The ploughs at either end are secured to rocking beams, which allow the rear ploughs to be turned up out of the way; or both gangs may be elevated in turning or moving the machine to or from the field. Small wheels at the extremities act as steering wheels, and regulate the depth to which the ploughs enter the ground. Each driving wheel is surrounded by a "portable track" endless belt, to which blocks of wood or metal are attached. Clearers formed like double mould board ploughs are placed in the track of the off-side driving wheel, one before and the other behind. They are so connected by rods and levers, that when the forward one is in operation, the rear one will be lifted up clear from the ground. The advance motion of the forward clearer opens the furrow, while the reverse motion of the other fills it up again. The boiler and engine are placed in the centre, immediately over the driving shaft for balancing the apparatus. *Patent completed.*

959. D. AULD. *Improvements in working furnaces and steam boilers, and in apparatus connected therewith.* Dated April 29, 1858.

This invention was described and illustrated at page 553 of the "Mechanics' Magazine," for Dec. 11, 1858, No. 1844. *Patent completed.*

960. R. B. H. DE LOWENDAL. *Improvements in the construction of springs, and for their new application to the working machinery.* Dated April 30, 1858.

This consists in so shaping metallic or other springs, that they shall have more than one curvature, so that in one portion of the spring at least there shall be a duplication of the curve. *Patent abandoned.*

961. J. CHADWICK, A. ELLIOT, and W. ROBERTSON. *Improvements in machines for twisting and winding silk, direct from the cocoons, such machines being of the class commonly known as throstles.* Dated April 30, 1858.

This relates to a former patent granted to J. Chadwick and T. Dickens, in 1858. The present patentees impart such difference of motion to the spindles, and bobbin tubes, as may be necessary to put the requisite spin or twist upon the silk as it is wound on the bobbin. The apparatus is not described by the inventor apart from his drawings. *Patent completed.*

962. J. LUIS. *Proper apparatus for separating two substances of different densities; among others may be mentioned pit coal from the slate which it contains.* (A communication.) Dated April 30, 1858.

This apparatus is divided into three principal parts:—1st. A washing table, on which the separation of the substances is carried on. 2nd. A labyrinth, where the lighter matters are deposited. 3rd. A reservoir for denser substances. It is not easy to explain it without the inventor's drawings. *Patent abandoned.*

963. B. E. G. DE BRUN. *Leather tissue and other tissues rendered waterproof by a new process.* Dated Apr. 30, 1858.

Into linseed oil the patentee throws litharge and brown umber, in powder, and hydro-protoxide of manganese, which has been first subjected to a slow fire, with some linseed oil. He mixes all together, then lets them settle. When he wants to use this oil for a cotton, linen, or like tissue, for the first coat he mixes water with the oil, and heats them both until perfectly mixed. Then, by a sponge, he spreads this oil and water all over the tissue, and leaves it to dry. Then to the oil mixed with water he puts lamp-black and makes a paste, which he spreads on the tissue by a small iron scraper. If the tissue employed is thin, and it is wanted to dry quickly, the oil mixture must be boiled; then salt of lead, turpentine, and lamp-black are added to form a paste, which serves for a second coat. The operation continues in all cases by fresh coats of the oil mixture not boiled, till the bottom of the tissue is well made, taking care to pounce or polish the tissue, to make it close and even. After this it must be made black or coloured, dried, pounced slightly, and varnished with a varnish formed of common oil boiled with brown umber, litharge, and Prussian blue; turpentine is added when the oil thus composed is three parts cold. When the tissue is perfectly dry it is passed under an engraved cylinder, to give it the appearance of grained neat's leather or morocco, if it is to have this appearance. The tissue is waterproof, and can be used for boots, hats, furniture, &c. *Patent completed.*

964. B. L. A. PENCEALLIER. *An improved plough.* Dated April 30, 1858.

This is composed of the body and what may be called tail of the plough, which contains four shares. The axle has a vertical support of two uprights meeting at the top by a central part traversed by a screw for earthing or unearthing the plough. This screw acts on a half-circular branch of iron, which supports a cast iron box. Behind the body are two riving knives, and the shares for opening the first furrow. The special character of this plough consists in its power of turning at the end of the furrow. To effect this, the handles are placed horizontally, and on pulling a spring placed against the body of the plough, a half-revolution is effected. The handles are then placed according to the necessary slope, where they are fixed by a shaft of iron which unites them. The ends of the shares can be raised or lowered by a screw, and can be separately earthed or unearthed. *Patent completed.*

965. E. T. HUGHES. *An improved regulator and float combined, applicable to the manufacture of paper.* (A communication.) Dated April 30, 1858.

The patentee employs a combination of regulator or governor and float connected with suitable apparatus, so that a continuous delivery of pulp may be obtained, independently of the variation in the speed of the paper machine, and also of the variations in the level or depth of the mass in the large vat or reservoir. The apparatus is not described by the inventor apart from the drawings. *Patent completed.*

THE
MECHANICS' MAGAZINE.
LONDON, FRIDAY, JANUARY 7, 1859.

WHILE all the world is keeping holiday, and London is lying "unseen, yet sounding through its shrouding mists," we shall prefer occupying our opening columns this week with a few paragraphs on matters of general interest, rather than with formal articles of a more technical and troublesome character. And, first, a word or two to our subscribers. We have received several requests to publish a weekly table of contents, and also to discontinue numbering the advertisement pages with the others. To both of these requests we have cheerfully acceded, as our readers will observe. We shall take care at the end of the first volume, so to number the index, or some other introductory matter, as to supply pages 1 to 4, of which, when the advertisement sheets of last week's number are removed, the volume would otherwise be deficient. The first volume will thus be made complete, and consecutively paged throughout, as our correspondents desire. We have to apologise for the lateness of our last week's issue, for the somewhat unfinished appearance of a portion of our impression, and for the scarcity of our Abridged Specifications of Patents. All these things were contingent upon the *first* appearance of the Magazine in its new form, and will not, we confidently believe, occur again. In respect to the Abridged Specifications, we wish it to be understood that we shall soon bring them up to date, and then publish them regularly, week by week.

DR. LIVINGSTONE sends us news from Tete, on the Zambesi. He has been much hampered by the great draught of water of the *Pearl*, which, it will be recollected, was appointed to see him fairly, and as far as possible, on his expedition. He adheres to the opinion he has all along expressed—that a vessel drawing from four to six feet of water, could run upon the river seven or eight months of the year; and adds, from further observation, that it could be navigated nearly, if not entirely, throughout the year with still lighter vessels, say, of thirty inches' draught. What a pity it is that we could not furnish our renowned explorer with a craft like that which El Hami Pasha has had built for his pleasure by Mr. Scott Russell! When will the English nation be capable of doing as much for itself as a mere Turk, with his handful of piastres, compels it to do for him? The heroic doctor was further troubled by the difficulty with which the *Pearl* backed, when her screw was reversed, in feeling the way along the river's channel. Having entered the river by a side branch—possessing a very good bar and harbour—and explored the delta for about a month, the river was found to be fast falling. To prevent the detention of the *Pearl*, which he was stringently ordered not to delay, the Doctor landed all his goods on an island, and, at the time of writing, was carrying them up to Tete by successive trips in his small steam-launch. The news sent by him is most encouraging and important. He arrived in the midst of a war between the natives and Portuguese, but, observing a clear neutrality, he has been treated with friendliness by both the belligerent parties, and is endeavouring to push away beyond them with all speed. Of the Zambesi itself he speaks very favourably, entirely confirming the opinion expressed by the two naval officers who accompanied him. On reaching Laputa, where the river is no longer divided into many channels, all difficulties in navigation ended. Here, at DOCTOR LIVINGSTONE'S suggestion, were dug a ton and a-half of coals, the very first ever taken out of the earth in that country. Mr. RAE, "a Glasgowegian," pronounces them to be good, and promising better, as they are got from the surface, on the bank of the Muatoze, where they have been exposed to the action of the floods and atmosphere for ages. There is an immense coal-field there, and many of the seams crop out. With coal, and the best iron ore in abundance, surely Africa will not always be the trodden-down nation it has been. Their vessel was the first that ever steamed to Tete, and was visited as if it had been another Leviathan. "It is sad to see so fine a country," says the estimable Doctor, "in this state. We meet some very fine cotton, growing wild, wherever it has once been sown. It is long in the staple, and has been introduced, as its name imports. The other has a short strong staple which clings to the seed, and is more like wool in the hand than cotton. We have also more lignum vitæ than ebony. . . My men were still at Tete, though 30 of them had died of smallpox, and six had been killed by a neighbouring chief. The poor fellows received me with great joy, and no less glad was I to see them. All the party is now well. We have had illness, but no coast fever. I think as both we and the *Pearl* escaped, it was greatly owing to pushing with all our vigour away from the mangrove swamps at the mouth of the river. These are the hotbeds of fever."

PHOTOGRAPHIC DRAWING ON WOOD, for the purposes of the wood engraver, has this week been most satisfactorily advanced. A conversation with Mr. CROOKES—whose name is well-known among photographers, and who has recently become the editor of the best of all photographic journals (the *Photographic News*)—prepared us some months since for the reception of the improvements which are now made public by that gentleman. He covers the wood block with oxalate of silver and water, to which a little gum or pulverised bath-brick may be added if desired. The material is spread over the wood in the same manner as the engraver's ordinary flake-white and gum-water are applied, a delicate and almost impalpable coating of the oxalate being thus produced. The block may then be placed in a drawer, or in any place from which daylight is excluded, and there left to dry, or until required for use. When taken out and exposed to sunlight under a negative in the printing frame, a positive picture will be produced upon the block, as it is upon paper in the ordinary way. A block thus prepared is ready, without any further process, for the engraver's hands. In cutting it, he need only be careful not to expose it to the direct rays of the sun; diffused daylight will not blacken it, except by many hours of exposure. By this process all kinds of pictures may be transferred to the wood block; and the inventor sees no reason why it may not be applied to the reproduction of stereoscopic views, which would bring them within reach of the humblest. A use which is more important to us is that of applying reduced mechanical drawings, and photographs of machines themselves, directly to the wood. This would save much time, and, in the main, conduce to greater accuracy than is usually attained at present. These applications must, however, be made with care, for there is sometimes a disposition, either in the sun, or in the chemicals, or in the manipulator, to introduce twists and turns which, in portraits at least, we know not always how to tolerate. We remember that DE QUINCEY once complained of the excessive proportions which his mouth, and most other mouths, acquired whenever the sun painted the picture; and there are many parts of machinery which will bear distortion even less than Mr. DE QUINCEY'S features.

THE SHIPPING STATISTICS AND TONNAGE QUESTION is again revived in our columns this week, by the publication of the Report of the British Association's Committee. The same question also recurs in a correspondence publishing in the Society of Arts' Journal. Mr. MACGREGOR, of the Temple, there opens the subject in a letter on Mr. REED'S paper on the Ships of the Royal Navy. Mr. MACGREGOR states that, having seen the Turkish ships at Sinope before the battle, and other avowedly large ships in America, he has found that Turks, Americans, and Russians, all exaggerate the sizes of their vessels when it suits their purposes; and he says, "it is extraordinary that men will continue to compare the tonnage of vessels, as if a proper standard were actually in use." Mr. REED, in reply, admits the imperfection of the existing rules for calculating tonnage, but contends that they form the best basis of comparison which we at present have, and shows that he carefully bore in mind the discrepancy between the English and American rules in making the comparison between the *Shannon* and the *Merrimac*—the only comparison instituted by him. He adds that the tonnage question has lately had such a mountain of words heaped upon it that he made no attempt to exhume it before the members of the Society of Arts. The report referred to will come under our consideration in due course.

PREMIUMS FOR INVENTIONS are again offered by the Council of the Society of Arts, and gentlemen having a love of distinction, gold and silver medals, and pounds sterling, will do well to apply to the Secretary for a list of subjects for improvements in which prizes will be awarded. Under the will of Dr. SWINEY, a silver goblet, worth £100 sterling, containing gold coin to the same amount, will be presented on the 20th of January next to the author of the best published treatise on Jurisprudence. A special gold medal, provided by the gift of Benjamin OLIVEIRA, Esq., is also to be given for a substitute for cotton; and other special gold and silver medals for an incombustible paper, and a design for a Literary and Scientific Institute. An abundance of the society's ordinary gold and silver medals is also ready to be scattered among men possessing either genius or ingenuity. They may patent their inventions and still win the prizes. Let inventive brains and diligent hands become busy!

THE NAVIES OF ENGLAND AND FRANCE form the subject of a lengthy paper transferred to the *Times* from a German publication entitled the "Conversations Lexicon," published at Leipzig. The most remarkable feature in this paper is the prominent notice it takes of the modern expansion which the French navy has undergone. In this respect it has a decided value, and deserves the attention of the English people. It is written, however, with undue partiality; is in many places very erroneous, and owes its position in the leading journal to its undue depreciation of our present navy, the nature and strength of which its author but imperfectly comprehends. This we shall probably show in an early number.

THREE NEW MASTER SHIPWRIGHTS have this week been promoted to the Dockyards of Devonport, Sheerness, and Pembroke Dock. The Devonport vacancy has been filled by Mr. JAMES PEAKE, late assistant at Woolwich Dockyard, who has acquired eminence in consequence of his services in devising and superintending the construction of life-boats; Mr. HENWOOD, late assistant at Chatham Dockyard, and a member of the late School of Naval Architecture, has been appointed to fill the vacancy at Sheerness; and Mr. CRADDOCK, late assistant at Portsmouth, also a member of that School, proceeds to Pembroke Dock.

[THE LATE HENRY CORT.]

THE CASE OF HENRY CORT, AND HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

By THOMAS WEBSTER, M.A., F.R.S, &c., &c., Barrister-at-Law.

No. I.

THE history of inventors and inventions presents many features well-deserving consideration. The authors of inventions which have enlarged the boundaries of science, have extended the dominion over matter, have added to the comforts and conveniences of man, or have increased the power and wealth of the nation to an extent which can hardly be estimated, have lived neglected and died unrequited for the benefits conferred on mankind. In some cases the inventors have lived, so to speak, before their time; in others, the difficulty of introducing an invention, however meritorious, by reason of the opposition of existing interests—a difficulty not unfrequently proportionate to the merits of the invention—or the apathy and indifference of the public to changes not actually forced upon them, or the jealousy of competitors, present sufficient causes for the lamentable fate of many whom posterity regard as the great pioneers in the domain of social science and the progress of useful inventions. This is so notorious, that the hard lot of some of its greatest benefactors of their country, as authors and introducers of useful inventions, has been made matter of national reproach. Instances, however, are not wanting in which liberal rewards have been granted by Parliament, or by the Government of the day, to such benefactors, either by the grant of large sums of money or by pensions, or by appointment to important and lucrative situations. The real difficulty lies in the due appreciation of the individual merits amidst the host of persons who, in the case of a successful invention, claim to have had some share in contributing to that success. Nor are such claims altogether ill-founded; the history of abstract as well as of practical science shows how difficult of attainment and how small are the steps, so to speak, of discovery or invention when viewed alone or independent of their combinations or applications as part of some system, and as conducive to some special results, and when dissociated from, or not associated with those elements and conditions which are essential to a successful system. Hence it follows that the merit of the individual is rarely fully and duly appreciated by his contemporaries; and in this, as in many other cases, it must be reserved for the historian and for posterity to do that justice which can hardly be expected at the hands of contemporaries.

But in addition to the difficulty of duly appreciating the merit of the individual who may have contributed to a successful invention, there is not unfrequently considerable difficulty in estimating the merit of the invention. The merit in general is a question of degree; the invention has to be compared not only with what preceded, but with what succeeded it—with the new creations, so to speak, which it has called into existence. Experience and the test of time alone can authoritatively decide on the merit of an invention as an absolute step in the progress of knowledge, however it may appear in relation to those by which it is surrounded. Invention is and must be in its very nature ever progressive; the steps in that progress may be unduly regarded at the time, but the course of improvement will ere long clearly indicate those steps which mainly established the existing state of advancement.

In connection with this subject, it would not be right to disregard or omit all mention of the operation of the system of patents which has been adopted as a means of encouraging inventions, and of reward and remuneration for their introduction, and by which each individual is felt to make the best of the property so recognized in the products of his ingenuity, so that the inventor who fails by such means to derive that reward and remuneration which he might reasonably have expected, must be regarded as presenting an exceptional case.

If the discovery be one not the subject of those laws, he has a distinct claim as a public benefactor on the consideration of his fellow-citizens for some remuneration in respect of his labour and expenditure of time, money, or other capital, and for some reward according to the benefits conferred. If the discovery or invention be one in respect of which those laws give such special property, and the inventor has thought fit to forego, or neglected to avail himself of this advantage, he may have claims on the public similar to those existing in the former case, if the discovery or invention be one which may be thus thrown on the waters and abandoned to it fate. If the inventor, having availed himself of the law, and created property in his invention, has failed to receive the remuneration and reward which he might reasonably have expected, an exceptional case is at once presented, the special circumstances of which will require careful consideration before the claim which may be made can be acceded to.

For such exceptional cases, special legislation was provided in 1855, by Lord BROUGHAM'S Act, whereby the Crown was empowered to grant an extension of the exclusive privileges in cases of the authors of meritorious inventions, for which no adequate reward and remuneration had been derived. The exercise of this power, on the recommendation of the Judicial Committee of the Privy Council, has provided for the ordinary cases of want of adequate remuneration and reward; but exceptional cases are still of occasional occurrence, requiring special consideration, for which that recent legislation affords no relief.

Amongst such, the case of Henry Cort, the successful introducer of the manufacture of iron, as at present practised, stands most prominent, presenting, as it does, peculiarities which distinguish it from all others.

Public attention has been from time to time called to this, perhaps the most exceptional of all such exceptional cases; and it may be hoped that the survivors of the children of this most meritorious inventor may not be permitted to languish in penury, amidst the universal recognition of the wealth created for the nation by the genius and enterprise of their father.

THE THEORY OF NAVAL ARCHITECTURE.

No. I.

THE theory of naval architecture is readily seen to divide itself into two parts, the first embracing questions which relate to vessels floating quiescently upon the water, the second comprising those which relate to vessels moving through the water under the action of some propelling power. The whole of the questions in the first division may be solved in all their ramifications, like other statical problems, as certainly as any proposition in plane geometry. In the second division there are many which might be similarly solved, at least in parts, since a body in uniform motion may be looked upon as being in statical equilibrium, and there are consequently relations known to exist among the forces exerted upon it, although the forces themselves—depending as they do for their amount and the directions of their action upon the laws of the resistance of fluids—are unknown to us.

The first division is very extensive, and every constructor who wishes to know what kind of ship he is designing, and what qualities it will possess, should be able to investigate for himself the considerations embraced by it. Of the second division, the principal questions relate to the position in the ship of the masts and spars, or rather of the centre of effort of the wind on the sails as regards both length and height, in order that the ship may work well with a given amount of canvas, and not heel over to too great an angle under it.

In considering the construction of a new ship, the first conditions which have to be fulfilled are that the ship when built, rigged, stored, and manned, may be able to carry the required cargo, if she be a merchant ship, or the required armament, ammunition, &c., if she be a man-of-war—if a steamer, the engines, boilers, and sufficient coal besides. The ship must carry these without either sinking too deeply in the water, or floating too lightly upon it. These conditions must also be fulfilled with minimum dimensions, for in proportion to the size is the cost of the vessel; to build a larger ship than necessary is to incur unnecessary expense; to build one too small to carry her weights is to render the whole expense useless.

Archimedes, nearly 300 years before the Christian era, showed that the depth to which any floating body sinks in the fluid, is such that the weight of the fluid displaced is equal to that of body. We do not, however, find that the observed fact was then taken advantage of for practical purposes. In early times in England, probably until Sir Anthony Deane became the constructor of ships for the Royal Navy, new ships were mere copies of others already in existence, with trifling alterations to answer particular purposes, or to correct existing defects. Constructors could not then move far out of the beaten track, but had to wait patiently for results until the structures which they reared floated in their native element. Pepys, in his Diary, 1666, says:—"Mr. Deane and I did discourse about his ship, the *Rupert*, which succeeds so well, as he has got great honour by it, and I some by recommending him. The King, Duke, and everybody say it is the best ship that was ever built. And then he fell to explain to me his manner of casting the draught of water which a ship will draw beforehand, which is a secret the King and all admire in him, and he is the first that hath come to any certainty beforehand of foretelling the draught of water of a ship before she is launched." The secret referred to was this:—That the weight of a volume of water equal in bulk to the part of the ship below the water's surface, is always equal to the weight of the ship and its contents; and possibly, though not probably, the corollary from it,—that the

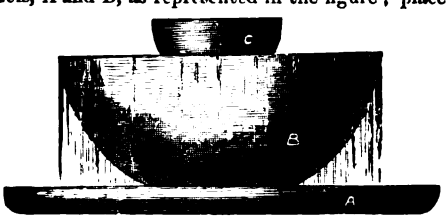
Digitized by Google

centre of gravity of the volume of water displaced is always in the same vertical as the centre of gravity of the ship and its contents.

These propositions we shall now prove. Let C

be any floating body, a ship, for instance, and A B the surface of the water. Imagine the body to be lifted up vertically out of the water, and the water surrounding the ship to retain the imprint after the body has been removed; and further imagine this space to be again filled with water to the same level as before. The volume of water in this space is evidently the "volume of water displaced by the body," and it is called, as is also its weight, the DISPLACEMENT. Its centre of gravity is denominated the CENTRE OF GRAVITY OF DISPLACEMENT; or, more briefly, THE CENTRE OF BUOYANCY. The particles of water which we imagine to retain the imprint of the body, now support the volume of water which the body displaced, in the same manner as they supported the body itself when it was immersed. Each of these—the water displaced and the body immersed—must then be supported by the same pressure acting upwards. And since the weight of the body would be sustained by the same upward pressure as now supports the weight of the water displaced by the body, *the weight of the floating body must be equal to that of the water displaced—that is, to the Displacement.* Again: When the body is immersed, the pressure downwards is the weight of the body—the pressure upwards, a pressure equal to the weight of the water displaced. These two may be considered as forces acting the one at the centre of gravity of the body, and the other at the centre of gravity of the displaced water, each in its respective direction, and the two being equal to each other, there can evidently be no equilibrium unless their lines of action coincide—that is, unless *the centres of gravity of the body and of the displacement lie in the same vertical line.*

That the weight of the water displaced by a floating body is equal to that of the body and all its contents, may be practically proved by apparatus within the reach of every one. Take two vessels, A and B, as represented in the figure; place



one within the other, and fill the upper one with water to the brim: then take another empty vessel, C, and lower it gradually into the water in B, until it is supported by the pressure of the water. When C is at rest, a volume of water equal to that displaced by it has run over into A; and if this water be placed in one side of a pair of scales, and the vessel C in the other, they will be found to balance each other. Replace C in the water, and gently drop some heavy material, such as sand or shot into it, and more water will overflow; remove C with the material it contains carefully to one end of the balance, and add to the water before put in that which was caused to overflow by the introduction of the material into C, and, as before, the water will balance the vessel and its contents. This may be often repeated, until C sinks nearly to its upper part, and it will be found in every experiment that the weight of the water which has overflowed from B is always equal to that of C, and of the material it contains.

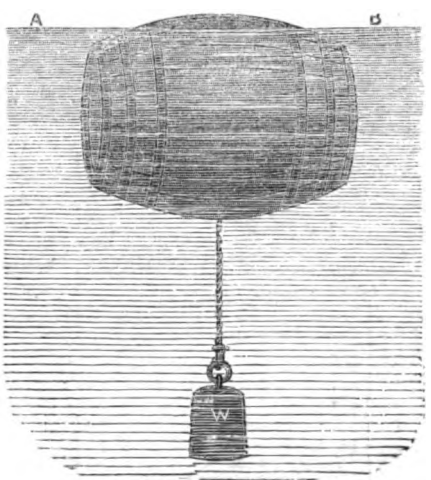
From these practical proofs of the equality which always exists between the weight of the floating body with its contents and that of the water displaced, we also learn that for every weight put on board of a ship there is an equal weight of water displaced by it. Of the knowledge of this fact we shall avail ourselves when we have to discuss the question of stowage, and we shall find that, by its judicious application, our calculations will be found very much abridged when compared with those generally in use.

That the centre of gravity of the ship with its contents is always situated in the same vertical line as the centre of gravity of the displacement, does not admit of a simple practical illustration, inasmuch as the centre of gravity of any floating body and its contents is not generally directly obtainable. But an ingenious person will have no difficulty in proving it by experiment to his own satisfaction. As we said before, however, this follows as a necessary consequence from the equality which has been proved to exist between the pressure of the water upwards, and the weight of the body downwards.

In consequence of the necessity for this equality of the weight of the ship and of the water displaced, we perceive that, if the water in which a ship floats at different times differs in density, there will be a corresponding difference in the immersion of the ship. Now, the weight of a cubic foot of sea water is a little more than 64 lbs., and the weight of a cubic foot of river water about one-fiftieth less. A line-of-battle ship like the *Agamemnon*, when ready for sea, weighs about 5,000 tons, and it requires 26 tons to increase her immersion one inch; consequently, were such a ship to come direct from sea into the river, keeping precisely the same weights on board, she would sink $\frac{5000}{50} \times \frac{1}{64}$ inches, or 4 inches (very nearly) deeper in the river than when at sea. Ships which have flat floors, and are full forward and aft—approximating, in fact, to the form of a rectangular box—as are some colliers, barges, &c., will sink just one-fiftieth deeper when in river water, than when at sea.

The necessary equality already discussed also explains why heavy metals swim in a vessel containing mercury in its ordinary fluid state. The specific gravity of mercury is about 13½, whilst that of iron is about 7¾; it will therefore be readily seen that a mass of iron, 13½ inches deep, with vertical sides, will only sink 7¾ inches in the mercury, and will float in the same manner as a piece of wood floats on the water.

We have already proved that a floating body presses downward, and is pressed upwards, by forces equal to its weight. If, now, a light air-tight vessel, such as an empty cask, be placed in the water, it will float, until it be loaded with a weight equal to the difference between its weight and that of an equal volume of water. Let one end of a rope be secured to the weight, and the other end to the air-tight vessel; throw the



weight into the water, and as soon as the equilibrium has been restored, it will be found that the vessel is nearly at the surface (A B) of the water, as represented in the figure, and the weight W hanging vertically under it, supported by the tension of the rope. It would be entirely immersed, were it not for the effect which the immersion of the weight and the rope has on the vessel, that effect being to raise it a little out of the water—the part emersed being equal to the volume of the weight and of the rope, diminished by a quantity of fluid the weight of which is the same as that of the rope.

On this principle, sunken vessels are often recovered in the following manner:—At low water, a number of empty casks, air-tight caissons, or one or two ships or barges, are attached by strong ropes or hawsers to parts of the sunken ship, and the ropes are hove in tight. As the tide rises, the vessels become more and more immersed in the water until the weight of the additional volume of water displaced by the whole of them equals the force necessary to raise the ship. When tide is nearly at its height, the vessels, with the sunken ship under them, are removed towards the shore until she touches the ground again. If the ship be then in such a position that the falling tide will leave her above water when at its lowest, the vessels are cast off: but if not, they are hove down as before, and the process described is repeated.

The number of air-tight vessels necessary to raise a sunken ship may be thus approximated to. On the sunken ship the pressure downwards is the weight of the ship and of the cargo, and the pressure upwards is the weight of a volume of water equal to that occupied by the materials of the ship and by the cargo. If the ship be built of wood, the specific gravity of the mass could not much exceed unity—that is, the weight of the whole mass would be about the same as that of an equal volume of water. There would then remain to be overcome by the water-tight vessels a pressure equal to the weight of the cargo when placed in water. This pressure can often be found very readily. When known, we must have a number of water-tight vessels, such that their weight, together with the weight of cargo when in water, shall equal the weight of the volume of water displaced by these vessels. If the ship be built of iron, with the usual amount of wood work, the weight of the whole would be about five times the weight of a volume of water equal to the bulk of the materials. In addition, therefore, to the difference of the weight of the cargo and that of a volume of water equal to it—that is, to the weight of the cargo in water—four-fifths of the entire weight of the ship has to be overcome by the pressure of the immersed water-tight vessels. We perceive, therefore, that although an iron ship may be lighter than a wooden one of the same tonnage, yet, were the two sunk with the same cargo on board, the labour necessary for raising the iron ship would be much more than that required for raising the wooden ship, as might have been expected.

It will be thought by some persons, perhaps, that these considerations do not belong to our subject. But it is only by such illustrations that fixed principles are gained, and the student in naval architecture is made familiar with the various phases under which the same problem appears, and it is our intention at all times thus to illustrate whatever we discuss whenever it can be made more clear by doing so.

To return to the displacement: we have seen that the displacement is always equal to the weight of the ship. The consequence of this is that the two are spoken of indifferently; and it is only when speaking of the centre of gravity of displacement, and the centre of gravity of the ship, that we are made aware by the terms that they are not synonymous.

The weight of any vessel cannot be very accurately assigned by calculating the weight of the several parts composing it, even when the timbers and planks are straight—as in some barges—because of the great differences which exist in the specific gravities of timbers of the same species. And in calculating the weight of a ship of the usual form in this way, besides the errors which creep in on account of the variations in the specific gravity of

Digitized by Google

the timber, others arise from the difficulty of obtaining the correct contents of curved timbers. These causes of error taken together render the result obtained by this method very questionable, even when the greatest possible care and labour have been expended in the operation. But, after the ship is completed and floating in the water, since we know that her weight is equal to that of the water she displaces, we have only to find the cubic contents of the part immersed, multiply it by the weight of a unit of volume of water, and the result is the weight of the ship and everything in it.

When the ship is of any regular form, the volume of displacement may be found by the ordinary rules of mensuration. Ships are, however, usually of no regular figure, their sections conforming to no other law than the will of the constructor; consequently, whatever methods may be employed to find the displacement, they cannot be more than approximations. These approximations, however, as we shall hereafter show, may be made to approach the actual amount as nearly as we please.

SHIPPING STATISTICS.

IT will be recollected that a committee was appointed by the British Association in 1857, to inquire into the statistics of shipping, with a view to rendering statistical records more available as data, and more conducive than heretofore to the improvement of naval architecture as respects the adaptation of the form of ships to the requirements of sea service. The committee so appointed consisted of the following gentlemen :—

Admiral Moorsom.	William Fairbairn.
J. Scott Russell.	James Perry.
J. E. McConnell.	Henry Wright.
Charles Atherton.	Andrew Henderson.

The committee, on commencing their proceedings, received letters from Admiral Moorsom, Mr. J. Scott Russell, and Mr. J. E McConnell declining their co-operation as members of the committee. The remaining members, however, agreed to prosecute the duties assigned to them, and W. Fairbairn, Esq., F.R.S., by the unanimous desire of the committee, undertook to conduct the proceedings as chairman, with the assistance of Henry Wright, Esq., as honorary secretary.

The following is the report which the committee made to the British Association at Leeds in 1858, the publication of which has not heretofore been authorised. We are indebted to the Editor of the Journal of the Society of Arts for an early copy, forwarded at our request.

The Report runs as follows :—

In the first place, the committee issued a circular, inviting statistical information as to the actual sea performances of ships, with a view to compiling a comprehensive statement as to the sea performances of vessels generally, whence the committee might be enabled to select a considerable number of vessels, of which the performances at sea may have been remarkable; and their attention being thus directed to a limited selection embracing a considerable number of vessels of practically established excellence for sea service, the committee hoped, after making due inquiry, to be enabled to present, as respects those vessels, a statistical exposition, in tabular form, of their various elements of construction and type of build; and thus, by a system of collation and induction, to discover practically those types and elements of construction which have been found by experience most conducive to good performances at sea. In the case of steam-ships, it was purposed that the statistics of the original trials to which steamers are generally put when new, should also be collected, classified, and collated with reference to the subsequent performances of the same vessels at sea, whence it might be determined to what extent and in what respects the usual smooth-water trials of steam-ships may be indicative of the probable properties to be expected of the same ships at sea, as respects their dynamic capabilities.

The committee are happy to say that this attempt at practically inquiring into the peculiarities of construction to which the good or bad qualities of steam-ships may be attributable, has not been wholly fruitless, for, although shipowners, ship-builders, and marine-engine manufacturers have been generally reluctant to communicate particulars whereby the dynamic merits of ships may be numerically classed and compared, the results of which classification and comparison might, if promulgated, affect the commercial value of their property, and the relative professional reputation of constructors, still, in reply to the before-mentioned circular, information has been communicated, as to the performance of vessels, particularly steam-vessels, by which it appears that a great difference exists between steam-ships as respects their economic capabilities for the performance of mercantile steam transport service, leading to the conclusion that the general aggregate of steam service is performed by vessels of inferior adaptation for economic duty, and consequently at a rate of prime cost expenditure, and, therefore, ultimate charge on the public, greatly in excess of that which would be involved if all steamers were of the superior class of excellence that has been already, in certain cases, actually attained. For example: this committee are assured, on authority which they believe to be unquestionable, that a certain vessel, the *Bremen*, of 3,440 tons displacement at the time of trial, propelled by engines working up to 1,624 indicated horse-power, attained the speed of 13·15 nautical miles per hours. Now if we esimate the dynamic duty thus performed by the formula $V^3 D^{\frac{2}{3}} = C$, we shall have the co efficient,

$$C = \frac{(13{\cdot}15)^3 \times (3440)^{\frac{2}{3}}}{1624} = \frac{2274 \times 227{\cdot}88}{1624} = 319,$$

(Ind. h.p.)

and this co-efficient of dynamic duty, resulting from the mutual relation of displacement, speed, and power, appears, from the statements which have been communicated to this Committee, nearly 50 per cent. higher than that realized by the average performance of the steam-ships of the present day. The following are the co-efficients of dynamic duty deduced by the foregoing rule from the performance of mercantile steamers of high repute, of which the trial data have been communicated to this Committee, viz., 325, 291, 291, 288 259, 218, 231, 230, and 201, and many others below 200.

This Committee, therefore, regard the *Bremen* as being a felicitous exemplification of naval architecture as respects type of form adapted for easy propulsion; and as we conceive that the promulgation of some of the constructive elements of this vessel may be of public importance, we are happy in being authorised and enabled, by Messrs. Caird and Co., of Greenock, the constructors of the ship and of the engines, to communicate to the British Association the following statistical data as to the elements of construction of the *Bremen* :—

Length between perpendiculars of stem and rudder post			318 feet.
Breadth of Beam			40 ,,
Depth of held			26 ,,
Mean draught of water at the time of trial			18ft. 6in.
Displacement (D) at trial draught			3440 tons.
Area of maximum immersed section (A) at the trial draught			606 sq. ft.
Distance of maximum section (A) measuring from the stem			159 feet.
Constructors' load draught		forw.	18 feet.
		aft.	19 ,,
Displacement at constructors' load draught			3440 tons.
Rate of ships' displacement at constructors' load draught			25 tons per inch.
Data for laying off Peake's curve of sections.	Area of immersed vertical section at the distance of ¼ length, measuring from stem		256·5 sq. ft.
	Do. ¼ Do. Do.		486 ,,
	Do. ¼ Do. Do.		606 ,,
	Do. ¼ Do. Do.		489 ,,
	Do. ¼ Do. Do.		253·5 ,,
Data for laying off curve of Displacement.	Displacement at draught of 4′ 7½″, being ¼ load draught		360 tons.
	Displacement at draught of 9′ 3″, being ½ load draught		1165 ,,
	Displacement at draught of 13′ 10½″, being ¾ load draught		2240 ,,
	Displacement at draught of 18′ 6″, or load draught		3440 ,,

The foregoing data afford all the particulars required for the construction of Peake's curve of vertical sections, whence may be deduced the position of the vertical line passing through the centre of gravity of displacement, and also the positions of the centre of gravity of the fore and aft bodies respectively.

It will be observed, from the foregoing data of the constructive elements of the *Bremen*, that the maximum immersed section is at the middle of the length, and that the vertical sections are in such ratio to each other, with reference to their respective positions, that the curve of vertical sections will be a close approximation to a parabola.

The ratios deducible from the foregoing particulars of constructive data, combining Peake's curve of immersed vertical sections with the curve of displacement, will give a close approximation to the type of form of the immersed hull.

The engines of the *Bremen* consist of two direct-acting inverted cylinders, 90 inches diameter and 3 feet 6 inches stroke, fitted with expansion valves capable of working expansively to a high degree. All parts of the engines are felted and lagged with wood wherever practicable, the lower 16 feet of the funnel being surrounded by a casing forming a superheating chamber, the steam entering at the lower end, and passing off at the top into the steam pipes leading to the cylinders.

(To be continued.)

THE SMITHFIELD CLUB SHOW.

(Continued from page 7.)

IN resuming our notice of the late implement show, we should not omit to mention the growing interest which is being manifested in the system of "guideway" steam cultivation, introduced and practised by Mr. P. A. Halkett, of 80 Chancery-lane, who is now engaged in forming a company to carry it out upon a comprehensive scale. Its general principle has been often described, and is probably known to most of our readers; but the attention of the agricultural public having been lately drawn to the subject from Mr. Halkett's paper, read before the Society of Arts, and which gave rise to an interesting discussion, we may be excused for saying a few words at this time. At a recent meeting, at the Freemasons' Tavern, when the guideway system of cultivation was discussed, several gentlemen spoke in very high terms of it; Mr. Mechi, Mr. Robert Scott Burn, and Mr. Wren Hoskyns, being amongst the number. The system (by which the whole operations of agriculture are proposed to be, and have actually been, performed by steam-power) consists in laying down, at intervals of fifty feet or more, permanent rails, upon which travels a locomotive cultivator, carrying its own motive power, and to the under-side of which are attached the various implements to be used in cultivating the land. On the headlands rails are laid at right angles to the former, upon which a shunting or traversing carriage moves, by which means the cultivator is transferred from one set of rails to another, or is brought to the homestead, where the engines can be used for thrashing or other barn operations. Upon this plan it will be seen that no weight bears upon the land, thus admitting of its being cultivated in any weather or state of the ground, leaving, it is said, the heaviest clay soil in a state of lightness impossible to arrive at where the weight of men, implements horses, or steam-power is constantly "poaching" it; whilst by consecutive ploughings in the same furrow, it can be cultivated to any depth required. The crops are carried off, and the manure carried on to the land by the same means as other operations are performed; and when we consider the great weights to be moved and the distances over which they must be borne, we may conceive some of the advantages of a smooth road, both as regards saving of time as well as of cost. The quantity, says Mr. Halkett, that can be ploughed per day with power suitable to a farm of 1,000 acres, is 25 acres, and three men are all that are required to conduct the

Digitized by Google

operation. This calculation, he states, is based upon work which has been actually and repeatedly performed. As, however, when time presses, a double set of men may be employed, double this amount of ploughing may be done in the twenty-four hours, the operation being capable of being carried on both by day and night. It must be apparent to all, that by no possible system could greater precision in the work be attained than by one in which, as in Mr. Halkett's system, every operation may be ganged almost to within half-an-inch. Indeed, hoeing has been done without injury to within that distance of the plants. The cost of the guideways, if of creosoted timber, is calculated at £10 per acre, or if of hard burned brick and angle iron, £20 per acre; while the cost per acre of various operations for a farm of 600 or 1,000 acres, is set down as follows:—ploughing 5in. by 10in. furrows, 1s. 7d.; hoeing, 3d.; scarifying, grubbing, &c., 8d.; harrowing, clod crushing, rolling, 5d.; drilling or dibbling seed, 5d; reaping (cutting and delivering) at 60 acres per day, 8d.; underground watering crops, at the rate of 3,000 gallons per acre, 1s.; surface watering, 1s. 2d.; carriage of manures, &c., 1d. per ton per mile; and, finally, deep cultivation, to the depth of 25in., 12s. per acre. The mode of cultivating to this depth has been performed by first using six ploughs, cutting six furrows simultaneously of five inches depth; then ploughing again to a further depth of five inches; and at fifteen inches below, through the subsoil of a hard yellow clay, an anchor was drawn, with a palm nine inches in width; thus ploughing and breaking up the ground to a depth of twenty-five inches. This depth of cultivation is sometimes attained by market gardeners by trenching, and, it is said, costs £10 to £12 per acre. Whether or no it be probable that more extended practice will verify the statements here made as to the cost of various agricultural operations, it is perhaps impossible to say; nevertheless, enough has doubtless been done to fully justify extended trials, especially when we remember how much success in agriculture, as in manufactures, depends upon methodical modes of working, which, when introduced in the latter case, have never failed not only to cheapen production, but also very greatly to improve the things produced. We trust Mr. Halkett may succeed in inducing those whose interest it is to set themselves soberly to work to test, on a sufficient scale, the importance of his system. During the show, and for some days subsequently, Mr. Halkett exhibited his cultivating apparatus in the neighbourhood of London.

Powis, James, & Co., of 26 Watling-street, exhibited their endless band-sawing machine, capable of being worked by hand or steam power, as also their circular-saw bench, also adapted for hand or steam power. These machines, although not new, have not, we believe, been before exhibited by the firm at any of the Smithfield shows. They also exhibited an admirable combined machine for morticing, tennoning, and plaining, capable of being worked with ease by hand-power, and performing the operations with the greatest nicety and very great ease.

Joseph Lardner, of Banbury, exhibited his chaff-cutting machines, the peculiarity of which consists in the knives being divided, thus rendering the labour of working more uniform, and, consequently, less exhaustive than when they are of the usual length. Another feature in these machines is, that the legs are made of wrought iron, the tops being cast as usual.

Dray and Co., of Swan Lane, exhibited, in addition to their usual collection of implements, a new hand-dibble, invented and made by Mr. H. Bek, of Lamberhurst, Kent. This dibble we carefully examined, and do not hesitate to say, that it possesses strength and simplicity in an eminent degree. It is adapted for sowing various-sized seeds, including mangold wortzel seed, as well as beans, and is capable of being easily adjusted to suit the particular work required to be performed.

Samuel Nicholson, of Newark, exhibited a new double-barrelled oil-cake breaking machine, with arrangements which allow of a much greater variation being made in the size of the broken pieces of cake than those hitherto made. Mr. Nicholson's oil-cake breaker, of which the one now noticed is an improvement, obtained a prize at the late Chester meeting.

Clayton & Shuttleworth exhibited one of their well-known single blast combined machines, which performs the various operations of bolting, thrashing, straw-shaking, riddling, winnowing, chaff separating, and barley horning. To this machine, in many cases, is added a blower and separator, for finishing the grain for market, the tail being separated from the good corn, and the whole delivered into four sacks—marketable corn, best tail, chicken corn, and light particles blown out before entering the screen. These machines are fitted with patent drums and improved straw shakers. The fixed barn works of this firm are well known, and combine thrashing and dressing machines, corn and tail elevators, necessary shafting, and a self-acting sacking apparatus, for weighing the sacks, and calling by a bell, at the proper time, the man in attendance to remove the full sack, and replace it by an empty one. Messrs. Clayton & Shuttleworth also exhibited one of their small horizontal fixed steam engines, about which we need not further remark than by saying that their workmanship is of the very best kind, and such only as can be ensured by the most perfect arrangements for their manufacture. Although this firm proceed very cautiously in the introduction of changes in their machinery, yet the adoption of nothing is neglected which they consider to be a real improvement to any of the machines which they construct. We believe of portable engines alone, they have turned out between 2,000 and 3,000 during the last few years—a great number having been sent abroad, the greater part of the foreign trade in portable engines being done by them.

William Cullingford, of Islington, exhibited his simple but very cleverly-arranged bird nets, which, when set, are entirely hidden from the bird, but which spring up and make a captive the moment the delicately balanced board upon which the bird alights is touched. The nets may be had complete for 10s. each, being chiefly intended for trapping larks.

Hughes and Sons, of the Great Dover Road, exhibited a new "ring" stone (Pym and Rand's patent), the object of which is to grind faster and cooler than ordinary stones. The top stone on this plan stands, while the bottom one runs. Messrs. Easton and Amos are fitting several of these stones to new mills; but those who are against innovations deem Hughes' ordinary 4 feet stones, with the dressing known as "fourteen threes," as the best. The new stones are beautifully put together, and if the principle upon which they are constructed be sound, which we think it is, there is no fear of failure as the workmanship is perfect.

A. B. Child, of 192, Tottenham Court Road, exhibited his new grain separator combining the action of the blast, screens, and suction, and suitable for dressing both English and foreign grain. These machines are made for cleaning from 300 to 400 bushels per hour.

Barrett, Exall, and Andrewes exhibited one of their two-horse portable engines, which, at the Chester trials, was found to be exceedingly economical in fuel; as also one of their well-known fixed horizontal engines, which gained the first prize at Chester. These engines, when equal to, or above, 10-horse power, are fitted with condensers, which greatly reduces the consumption of fuel. One of this firm's fixed horizontal condensing engines gained the 600f. prize and a gold medal at the Paris Exhibition, and was much commended by M. Caille, the well-known extensive manufacturing engineer of Paris.

As we have still upwards of thirty stands to notice, we must postpone further comment until next week.

PREMIUMS FOR INVENTIONS.

THE Council of the Society of Arts, in issuing a list of desiderata as subjects for premiums during the sessions of 1858–59, and 1859–60, urge upon their members and the public the importance of communicating detailed accounts of new processes in arts or methods of manufacture of any modifications by which these may be simplified, or labour saved, and of any novel application of raw materials, whether previously known or not, to useful purposes. It is quite possible that some of the things set down in their list as to be done may have been already accomplished; but, in such cases, the knowledge of them is limited. One of the objects of the society is to elicit discussion on the subjects with which it deals, to see that nothing is concealed which may in any way tend to promote the good of all, and to record facts and opinions. The weekly meetings, and the Journal of the Society of Arts, afford the requisite facilities for effecting this, and the council earnestly hope that the opportunities thus given may be taken advantage of. Patented inventions are not excluded from receiving the society's rewards. The society is willing to receive communications on subjects not included in the following list, but in all cases expressly reserves the power of rewarding any communication according to its merit, or of withholding the premium altogether. The degree of originality and extent of suggestions for improvements will have material influence on the adjudication of the award. All communications must be written on foolscap paper, on one side only, with an inch and a quarter margin. They must be accompanied by such drawings, models, or specimens, as may be necessary to illustrate the subject. The drawings should be on a sufficiently large scale to be seen from a distance when suspended on the walls of a meeting-room. In regard to colonial produce of all kinds, it is absolutely necessary that a certificate from the governor, or other qualified person should accompany the samples sent to the society certifying that they really are the produce of the particular district referred to. The samples should be sufficient in quantity to enable experiments to be made, and an opinion to be formed of their quality; and it is desirable that the cost price in the district from which they are forwarded should be given. In every instance the probable extent of supply, with the average yield, if cultivated, and whether similar articles have hitherto been exported from the colony, or not, and in what quantities, should be stated. All communications and articles intended for competition must be delivered, addressed to the secretary, at the society's house, free of expense, either on or before the 31st of March, 1859, or on or before the 31st of March, 1860. In the first case, they will be considered during the session 1858-59, in the second case during the session 1859-60. This restriction, as to the date of receipt, does not apply to articles of colonial produce, in respect of which this list is valid until the 31st December, 1860. A list of subjects for premiums may be had on application (by letter) to the secretary of the society.

THE CORT FOUNDRY AT GOSPORT.—There is a curious circumstance worthy of mention regarding the foundry at Gosport, in which the celebrated *Cort* worked out all his important improvements in the casting of iron. The foundry had been shut up for a long time, until a few years ago, Mr. Cunningham, the inventor of the now well-known "Cunningham System of Reefing from the Deck," took the premises for the purpose of working out his great invention. The foreman of the smiths employed by him, happened to be a very clever workman of the name of *Carofe* or *Cort*, and supposed to be a descendant of the same family as the great iron founder. Thus two great inventions, each of which has conferred upon the world incalculable benefits, have been wrought out in the same place, and the name of Cort has been in connection with both of them.

RAISING AND LOWERING SHIPS OR CANAL BOATS.

FIG. 1.

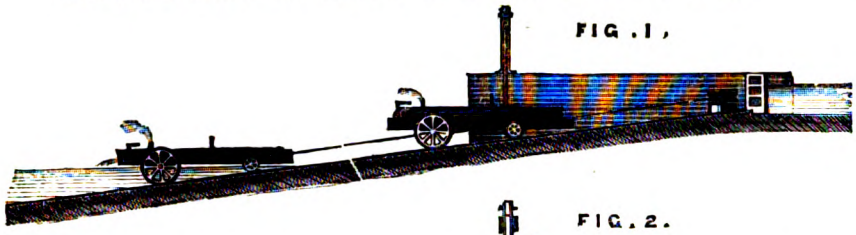

FIG. 2.

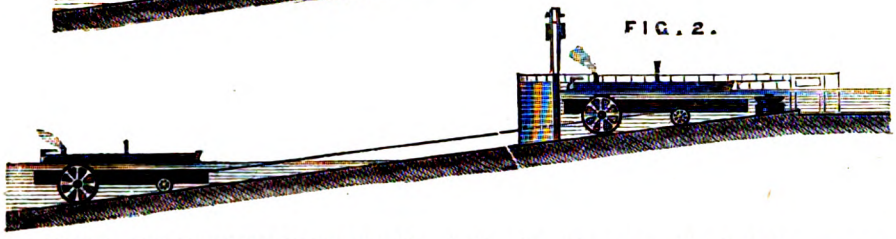


RAISING AND LOWERING SHIPS OR CANAL BOATS.

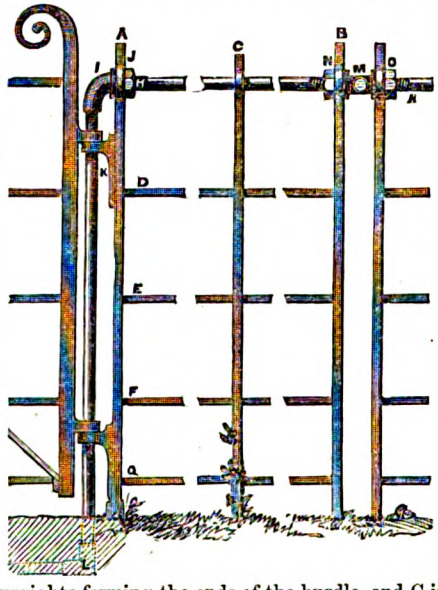
MR. T. FLETCHER, of Brackenley House, near Skipton-in-Craven, writes as follows:—

Herewith I send you drawings of a method of raising or lowering ships or canal boats from one level of water to another. I think you will find the drawings sufficiently intelligible not to require many observations from me. You will perceive it is worked on the self-acting incline plane principle; the moving power being an excess of water in the descending cradle. The cradle will be required to be all of iron; the perforation of the middle pier for the passing of the galvanised wire rope will require facing on both sides with a clow, so that the chain at the end of the rope being placed behind the clow, the clow put down, and the lock filled with water, the ship or boat may proceed. Fig. 1 illustrates the boats in motion on the cradles; fig. 2 shows the boats leaving the cradles.

The above plan, if applied in crossing an isthmus, or in place of canal locks (where there are a number together) would result in a great saving of time and expense in the conveyance of goods by water.

TUBULAR FENCING FOR IRRIGATION.

AN ingenious invention has been made by Mr. W. Bayliss, of the firm of Bayliss & Co., of Monmore-green, Wolverhampton. It has occurred to him that fencing might be so made as not only to possess improved strength and general appearance, but so also as to form a means for conveying water to troughs or cisterns, for the use of cattle, for irrigation, and for other purposes where water may be required. He effects this by making one or more of the fence or hurdle rails tubular, which may be conveniently done by forming them of common iron gas tubing, varying the size and number of tubes according to the quantity of water to be passed through them; and as the manufacture of the same description of tube necessarily involves the use of an extensively diversified shape of angle, and other connecting parts, the same appliances enable him to adapt this mode of constructing fencing in every possible way that water may have to be conveyed. For instance, the connection from one hurdle to another may be made either by forming a shoulder near the ends of the tubular rail, or by tapping the ends externally and screwing on a nut, so that the shoulders or nuts on each end shall form a bearing for the upright end rails to abut against. The hurdle being placed right, and the succeeding hurdle in continuous position, a common connecting piece may be placed between them, and screwed up to form a perfect and strong connection, white lead and washers being used to prevent leakage. As such connecting pieces are commonly made somewhat of a T shape, great convenience is offered for applying a lateral spout, tap, or plug, so that the water may be allowed either to flow on, or to flow out at these connecting parts, the supply being obtained from a reservoir suitably placed to ensure the desired pressure and supply. It does not of course matter if the tube is passed underground, when the water has to be conducted across roads or pathways, or from one permanent hurdle to another, with a swinging gate between- The annexed engraving shows a hurdle (the rails of which are broken, and the uprights brought near together for convenience in engraving). The top rail of it is tubular, and it is connected on the one side to a gate, and on the other to another hurdle. A and B are flat iron

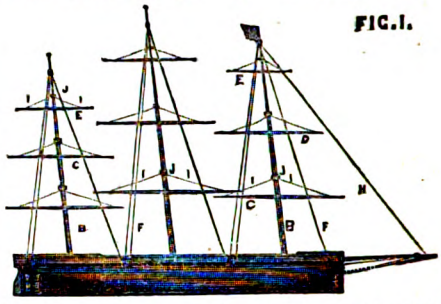


uprights forming the ends of the hurdle, and C is the centre support. The rails, D, E, F, and G, are of common rod iron. The top rail, H H, is of common gas-tubing, one end of which passes through the standard A, and is united by screwing the part I up tight, so as to confine the upright between this part and the nut J. The upright, K, K, is also a tube connected at top with the part I, and to an angle piece at the bottom, shown in dotted lines, showing how the water may, as we have said, be conducted underground. The connection of the gate to the fixed hurdle may be arranged in the ordinary way, or as here shown, viz., by making the vertical tube, K, K, form the axis on which the gate swings. The part I may be like the angle shown in dotted lines at L. For connecting the hurdles together, a connecting piece, as at M, may be used. It is a simple ordinary means of connecting gas tubing, and, by turning this around with proper tools, and regulating the nuts, N and O, a perfectly strong water-tight union may be formed. If desired, arrangements in these parts may be formed for supplying a suitable plug, or tap, or hose, for drawing off the water for any required purposes. Mr. Bayliss has patented his invention.

WEBSTER'S METHOD OF MASTING AND RIGGING VESSELS.

MOST of us know that "made masts" are greatly superior in strength to "single stick masts." Every piece of timber put into the former is, of course, sound and strong, or it would not be used for the purpose, but the latter is liable to be very rotten internally, without affording any external indication of the fact. Notwithstanding these considerations Mr. W. Webster, of Jefferson County, Washington, United States, has thought fit to patent in this country what he calls "an improved method of rigging vessels," the main feature of which is the use of single stick masts for all classes of ships. Fig. 1 is a diagram of

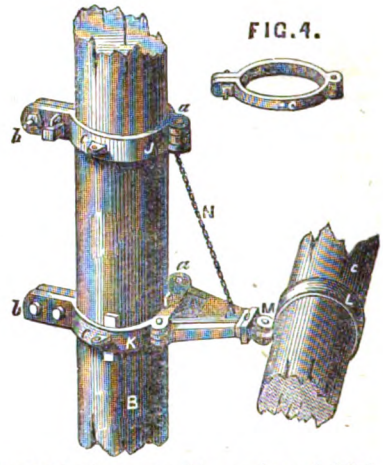
FIG. 1.



ship rigged according to his plan. A is the hull of the vessel; B, B are the masts; C, C, the lower yards; D, the topsail yards; E, the topgallant yards; F, the shrouds; G, the bowsprit; H, the jib-stay; I, the lifts; J, the slide bands to which the lifts are attached; K, that part of the truss band that embraces the mast; L, that part of it

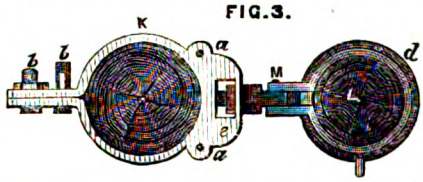
FIG. 2.

FIG. 4.



which holds the yard; M, a universal joint; N, chain slings; *a*, hinges; *b*, bolts; *b'*, clamp screws; *c*, eye bolts; *d*, annular sheave for rotating yards; *e*, yoke. Ship's masts are now usually made, he says, of three or four pieces by doublings, which necessitates a great deal of top hamper to secure and hold these pieces in place. and cumbrous contrivances to hoist and lower them; this top weight involves a decrease in the length of the

FIG. 3.



spars and in the spread of the canvas; it is also an important element in the cost of a ship. Abundance of sticks, long, straight, and large enough for a ship's mainmast, and of the proper material, can be obtained on the north-west coast of the United States, and probably in many other portions of the world. For smaller vessels sticks of proper dimensions are everywhere readily

Digitized by Google

obtained. The masts formed of them are secured to the hull by wire shrouds, F, F, placed at an unusually large angle with each other, and so that the lower ends of the after shrouds of the foremast are immediately contiguous to those of the forward shrouds of the mainmast, and so with the others. "A ship with masts and shrouds of this description will carry," says Mr. Webster, "with safety one-fourth more canvas than the ordinary amount, and will sail much nearer to the wind." The yards he makes much longer than usual, as shown, and secures them to the masts by an improved form of truss-band and slings. These bands, figs 2 and 3, are hinged at *a*, *a*, and have clamp screws, B, to hold them at any desired point on the mast, The yards are held in bands, L, hinged to a bolt, which rotates in a yoke, *e*, attached to and forming part of the band K which grasps the mast. This attachment is a universal joint, M, and allows motion to be given to the yards in every required direction. The lifts, I, are attached to hinged slide-bands, fig. 4, occupying the positions J, J, on the mast, fig. 1, that is, they are clamped to the masts at the proper distance above their respective yards. The hinge-bolt of these bands has a ring at its lower end, fig 2, to which the chain-slings of the yarn are hooked. There are also eye-bolts, *c*, in the sides of these bands, to which the lifts, I, are attached. The bands of the top-sail yard are slit, L, fig. 3, for the reception of a grooved hoop or sheave, *d*, which may be rotated in them as a sheave is rotated in an ordinary pulley. The yards, C, D, E, work inside the shrouds, and can be hoisted up or lowered down upon the rail as readily as sails are now hoisted and lowered, and when on the rail can be pointed nearly fore and aft. The topsail yard may be rotated on its own axis in its band by means of the annular sheave *d*, fig. 3, turning in the slit in the band. The bowsprit, G, he makes to run inboard; when it is thus run in and the yards lowered, the ship will present to the action of the wind only three bare poles and a few small wire shrouds. It will be observed that he does not connect the masts together by stays as in ordinary ships, relying upon the great inclination of the shrouds to give them the required stability; nor does he connect the bowsprit to the foremast by anything more than a small cord, H, which can be severed in an instant, and would yield of itself to a much smaller force than would suffice to carry away the bowsprit. "The effect of this arrangement is," he says, "that the loss of one mast does not involve the loss of the others, and the common accident of carrying away the bowsprit does not endanger the masts."

ON THE CONSERVATION OF FORCE.

(*Continued from page* 16.)

In very much of this essay, Mr. Grove endeavours to expunge from the mind the idea of force as an external reality, and to induce in the mind of his reader, the habit of regarding physical phenomena as various modes of motion impressed upon matter, force being a mere hypothetic mediate idea, demanded by psychological convenience, but having no objective truth. The only objective realities which he is inclined to admit are matter and motion. These are the two elements of various proportions of which Mr. Grove attempts to show all physical phenomena are consituted. Is it possible that science should gain anything from such an attempt? In order that such a proceeding may be of any considerable use it must be first shown that the ideas of the two elements, matter and motion, are themselves of a simple nature. Before we can say that the term or the notion of force as an outward fact is unnecessary for the knowledge of physical philosophy, and that the two ideas of matter and motion are all-sufficient, it must be shown that the idea of matter does not itself involve any idea of force.

If the subject here suggested be followed up, it will be found so difficult to determine which of the two terms, and which of the two ideas is the more important, and which first reaches the mind, that I think it only prudent to accept them both. It is said we only know force by the motion with which it impresses matter, and it may be answered we only know of matter from the forces with which its various particles interact on one another. To attempt to eliminate force from its companion ideas of matter and motion is not desirable, and cannot be successful. These three ideas, too, are distinct, and must not be regarded as interchangeable or convertible. Even as Mr. Grove has defined force, it cannot be regarded as identical with motion. And matter, though it is the connecting link between the other two, is conceivable apart from both. But he does not preserve the distinction. He is wise enough in his preliminary maxims and observations. When I follow him, however, to their application to practical particulars, I am induced to wonder how performances of such various merit could proceed from the same author. By his own definition above quoted, which is substantially identical with that ordinarily given by mathematical writers, force acting to produce motion is identical with pressure, which, associated with equal and opposite pressure, retains a body at rest. It is an established doctrine, that a definite force or pressure acting on a body, and unopposed, during a definite time, produces in that body a definite velocity, and that this velocity varies directly as the pressure and the time, and inversely as the mass or quantity of matter of the body. Hence it follows that, if a constant force has produced in a given body a given velocity in a given time, the force will be proportional directly to the mass and the velocity, and inversely to the time. To measure forces, therefore, by means of the motion which they generate, it is the custom to use the momentum, as it is called, or the product of the mass moved and the velocity produced in a second of time. It must be particularly observed that not the momentum or quantity of motion developed, but the relation of this motion to the time consumed in its production, is the real measure of force. If I were to take a cylindrical vessel of unknown section, one foot deep, fill it with water, and weigh the contents, I might take the number of pounds of water as a measure of the area of the sections of all such vessels of the same depth. But the two ideas are by no means convertible, and it would be productive of the greatest confusion to interchange the terms weight and area in most propositions involving these ideas. This is the ordinary doctrine with regard to a single constant force acting on a single body.

But forces never appear singly. Every force on one body is accompanied by an equal and opposite force acting on some other body. With every action there appears an equal and opposite re-action. From these two propositions it follows that every change of momentum impressed upon one body is generated at the cost of an equal and opposite change of momentum in some other body or bodies. For as there is no such thing as a single isolated force acting in one direction in a single body, so every change of motion involves the mutual action of at least two bodies The force acting on the one must, therefore, not only be equal to, but of the same duration as that acting on the other; and since momenta in equal times by equal forces are equal, the changes of momenta in the two bodies are equal in amount and opposite in direction.

This law of action and re-action, extended to the other changes of which the material world is susceptible, implies, in my belief, all that is true in the general doctrine of the conservation of force.

The key notion in the system of physical doctrine which Mr. Grove and others endeavour to teach, appears to be that the universe, on the whole, must be in a state of permanence—that no change in any place or any body of matter is isolated and absolute, but that every modification is compensated for by an equivalent counter-modification in some other body. But they far outstep the limits of this law and of truth at the same time. Take the following extract from Mr. Grove. It relates to impact, and appears to me to be neither related to fact, nor required by the general principle of action and re-action:—

"It may be asked what becomes of force" [motion should be meant] "when motion is arrested or impeded by the counter-motion of another body? This is generally believed to produce rest, or entire destruction of motion, and consequent annihilation of force: so indeed it may, as regards the motion of the masses, but a new force, or a new character of force, now ensues, the exponent of which, instead of visible motion, is heat. I venture to regard the heat which results from friction or percussion as a continuation of the force which was previously associated with the moving body, and which, when this infringes on another body, ceasing to exist as gross palpable motion, continues to exist as heat.

"Thus let two bodies, A and B, be supposed moving in opposite directions (putting for the moment out of the question all resistance, such as that of the air, &c.), if they pass each other without contact each will move on for ever in its respective direction with the same velocity; but if they touch each other the velocity of the movement of each is reduced, and each becomes heated. If this contact be slight, or such as to occasion but a slight diminution of their velocity, as when the surface of the bodies are oiled, then the heat is slight; but if the contact be such as to occasion a great diminution of motion, as in percussion, or as when the surfaces are roughened, then the heat is great, so that in all cases the resulting heat is proportionate to the diminished velocity. Where instead of resisting and consequently impeding the motion of the body A, the body B gives way, or itself takes up the motion originally communicated to A, then we have less heat in proportion to the motion of the body B, for here the operation of the force continues in the form of palpable motion: thus the heat resulting from friction in the axle of a wheel is lessened by surrounding it by rollers; these take up the primary motion of the axle, and the less, by this means, the initial motion is impeded, the less is the resulting heat. Again, if a body move in a fluid, although some heat is produced, the heat is apparently trifling, because the particles of the fluid themselves move, and continue the motion originally communicated to the moving body; for every portion of motion communicated to them this loses an equivalent, and where both lose, then an equivalent of heat results."

I must confess that I am by no means certain of my interpretation of this passage. I am not sure whether it is intended as a statement of facts *as they are*, or as they *ought to be*, according to the author's notions of physical propriety. Does heat result from impact only for certain absolute velocities of impinging bodies? If two persons come in collision, will the heat developed be less if they are on board ship than if the same thing happened on *terra firma*? Will not the heat which supervenes depend only on the intensity of the blow, which in turn depends only on the relative velocities of the impinging bodies? Suppose one body, A, in motion to impinge on another, B, at rest, and suppose their mutual elasticity is ½, and the mass of A = ½ that of B. In such a case the whole of A's motion would be transferred to B, and A would be reduced to rest. No motion of the masses could, therefore be supposed to be lost. Will any one pretend that no heat would be produced, and that heat would be developed if the bodies struck each other the same blow on board a ship, with different absolute velocities? Who would believe such a one? And how could he prove his point? There is no doubt that the same heat would appear in the case I have proposed as if the same bodies came into collision under any absolute velocities whatever, so long as their relative motion is the same. If the heat called forth in other cases of impact can be regarded as an equivalent of motion, apparently lost, then in this case, where no motion is lost, and yet heat is generated, there is an appearance of new force without an equivalent disappearance of the old. Thus Mr. Grove's own opinions appear to me to involve that creation of force to which, in general, he so seriously objects.

May not the true account of such cases be that the "force," or rather motion, which is said to be lost, is not motion lost at all, but that the two masses, with their motions after impact, are equivalent to their motions before impact? If they were moving in opposite directions, the motions destroyed are equal in amount and opposite in character, so that whether existent together or together destroyed, they are alike valueless at all stages of the phenomenon. May not the heat, too, which makes its appearance, be of the same double character as the motion lost sight of?

That there is a law of conservation of momentum I do not doubt, and there may be a law of conservation in relation to other natural phenomena. But I am quite sure that the advocates of the conservative doctrine who have hitherto come to my notice, have either mistaken the law altogether, or grossly misinterpreted it in its branches.

A MECHANIC.

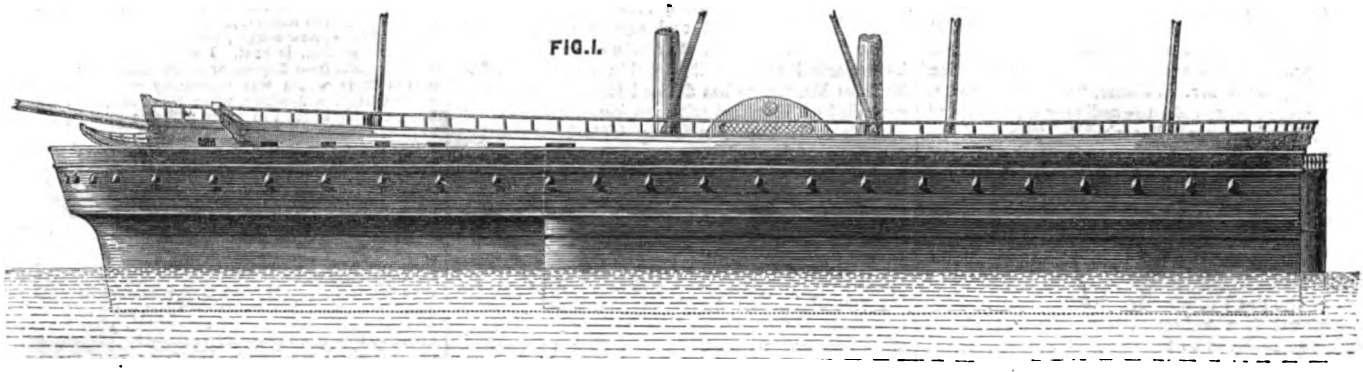
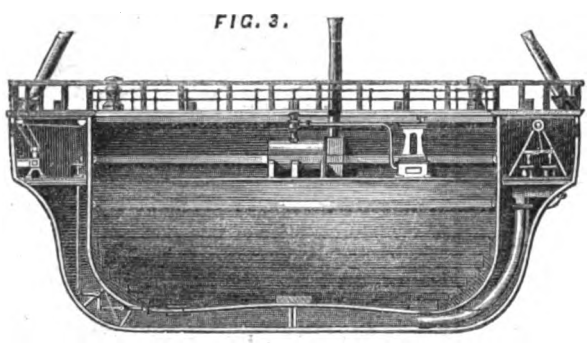
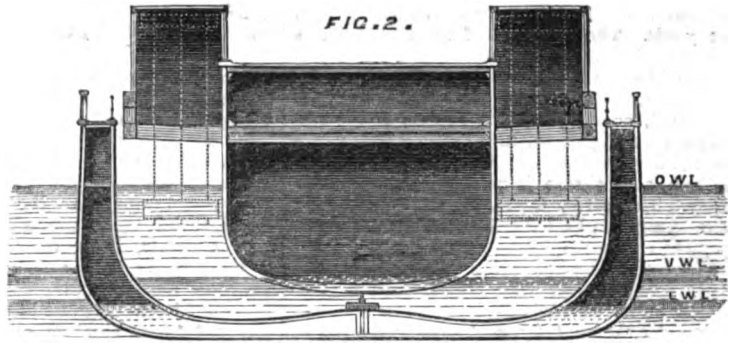
LENOX'S IRON FLOATING DOCK.







LENOX'S IRON FLOATING DOCK.

THE esteemed principal of the Chain Cable and Anchor Works, Mill Wall, Poplar, has favoured us with the following communication, and with the drawings from which the annexed engravings were made:—

GENTLEMEN,—Observing in your No. 1835 a description of a floating dock to be constructed of wood, proposed by Mr. Geo. Bayley, of Cowper's Court, Cornhill, in 1836, I was reminded of an arrangement I made for a similar purpose, to be constructed in iron, for which I took the preliminary steps for a patent in 1846. I had not then heard of any similar proposal, nor did Mr. Bayley's plan appear to be known at that time. I made a model with air-tight compartments, air pipes, and model of a brig, floating it in water, which I exhibited to several engineers, the late Mr. John Seaward, the late Colonel Brandreth, of the Admiralty, Mr. Denison, of Woolwich Yard (now Sir William Denison), and to the Lords of the Admiralty—all of whom expressed their satisfaction with my invention. Their lordships directed me to place the model again with Colonel Brandreth and Mr. Denison, for the purpose of estimating its practicability and cost; the working of the model was much appreciated by those gentlemen, as will be seen by letters from the latter, and by the former having asked for my specification of its construction and estimated cost, to place in his department in Somerset House. There it has, unfortunately, remained unnoticed ever since, under the care and keeping of Mr. Scamp, into whose hands Colonel Brandreth resigned it on quitting the office; Mr. Denison was shortly after appointed to the government of Swan River. I will venture to mention the origin of the idea, and then give you a short description, after which I will leave it in your able hands, to deal with it as you may deem it merits. I will premise by observing, that I am indebted, in a considerable degree, to the assistance and able services of my friend, Mr. Robert Murray, the brother of Mr. Alexander Murray, the Admiralty engineer of Portsmouth Dockyard, for the drawing out of the specification and description of my invention. About the year 1843, from a knowledge of the strength of iron, I was favoured with a visit from Mr. Murray, on behalf of Mr. Fairbairn, for the purpose of considering what size and strength would be required to construct some vessel or machine in iron, for the Emperor of Russia, that should supersede the pontoons used for floating the men-of-war over the bar, and out of the river Neva, to Cronstadt; but, after much consideration, we came to no result. About two years afterwards the idea struck me, that an entire dock might be made to float a ship, with her armament complete; and thus my model arose. I connected it with the possibility of war with a great neighbouring power, whose ships and forts might riddle our steamers, which, thus disabled, might at once run up to the Medway, or to Woolwich, where floating docks might be moored always in readiness, and enter them irrespective of tide, and out again in a few hours, returning to their work of mischief in the chops of the Channel. I now submit a lithograph of the dock, which I propose to make a complete dockyard, by the introduction of workshops and machinery around the main deck, and over the air-tight compartments, to be worked by the pumping engine, and a strong sheer-legs erected from side to side over the middle of the dock, for the purpose of masting the ships, putting in and out the boilers of steamers for repair, &c., &c. The construction of this dock is upon the principle since used in the *Great Eastern*, viz., double-sided, with internal divisions, &c. GEO. W. LENOX.

We have but little to add to this communication. The perfect practicability of Mr. Lenox's proposals experience has placed beyond doubt. The origination of so sound and useful an invention does him much credit. The floating dock has, in modern days, become comparatively common in countries where there is but little tide, but its use is unnecessarily restricted, and appears likely to be interfered with by more specious, but less efficient contrivances. The publication of Mr. Lenox's letter and illustrations may tend to counteract this circumstance, and to promote the adoption of the dock in many parts where it is much needed. But few will now doubt the superiority of iron to wood as a material for its contruction; and Mr. Lenox has drawn a specification of the construction, showing how it may be efficiently applied. Fig. 1 of the engravings is a side elevation of the dock, containing one of the Peninsular and Oriental Company's steam ships. Fig. 2 is a midship section of the same; O W L being the water line when the dock is open, and the vessel entering it; V W L the water line when the dock is pumped dry, with the vessel in it; and L W L the water line when the dock is empty, and pumped dry. Fig. 3 is a transverse section through the dock forward.

MAUDSLAY'S IMPROVED FURNACES FOR MANUFACTURING IRON.

EVERY engineer knows that immense expense is incurred in the manufacture of those large masses of wrought iron which have to be used for certain parts of steam-engines for which ordinary cast iron cannot, with security, be employed. After many years' experience, especially in connection with the manufacture of large marine engines for the Admiralty, Mr. Joseph Maudslay, of Lambeth, has instituted experiments with the view of producing an iron which should possess but little less strength than wrought iron, and at the same time be susceptible of being cast in moulds to the forms required; and he has been, to a very great extent, successful. The apparatus by which he effects his object is a rotating furnace, moving about an inclined axis, as illustrated in figs. 1 and 2 of the annexed engravings, of which fig. 1 is a longitudinal vertical section, and fig. 2 a transverse vertical section through the bed of the furnace. A is the fire-place; B, the feeding hole for the fuel; C, the inclined bed of the furnace, which is made to revolve about an inclined axis; D, an arched cover above the furnace, which cover is supported by a fixed iron frame, or casing; E, the door through which the furnace is charged with metal; F, a tapping-hole, through which the metal is run off; G, a roller-frame, upon which the bed of the furnace revolves; H, a bevel pinion gearing into the teeth of the wheel for giving motion to the revolving bed; K, a lower frame furnished with wheels, by means of which the revolving bed, after having been lowered by the screw L, may be withdrawn from beneath the arched cover, for repairs or otherwise. The

FIG. 1.

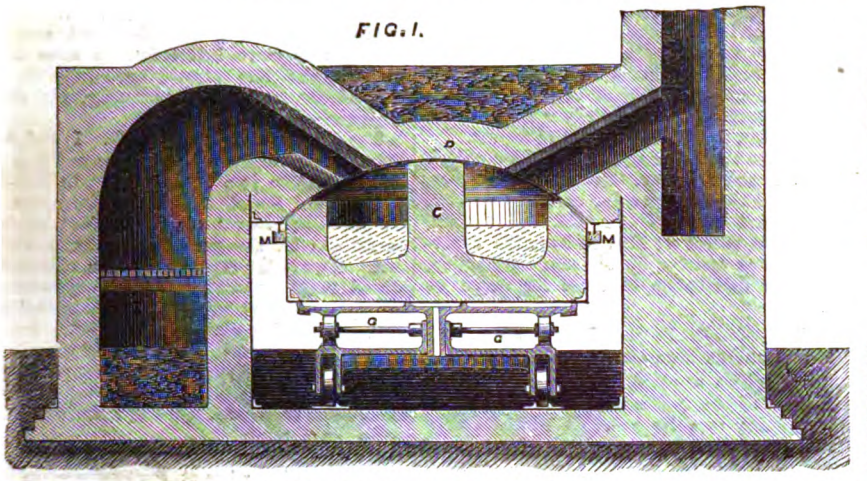

FIG. 2.

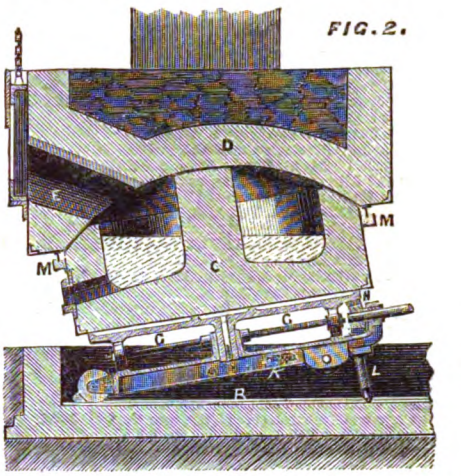

wheels of the lower frame run upon rails, R; M is a sand-joint for preventing the access of cold air into the furnace between the fixed top and the revolving bed; N is the flue leading to the chimney. The arrangement of the furnace above described is the best with which the inventor is at present acquainted for carrying his invention into effect, but he does not limit himself to the details thereof, as they may be variously modified.

By keeping the metal stirred about for some time whilst in its molten condition, by means of the rotating furnace, the sulphur and other impurities contained in it are allowed to readily fly off, so that the apparatus answers, in some measure, the purpose of a puddling furnace, and leaves the metal itself in a semi-puddled state, somewhat approaching the condition of wrought iron, but still with sufficient fluidity to allow of its being run into moulds and used for many purposes for which wrought iron is at present employed.

The axis of the improved furnace is placed by preference about 10° out of the perpendicular.

SIR JOSEPH PAXTON'S IMPROVED HORTICULTURAL BUILDINGS.

FIG. 1.

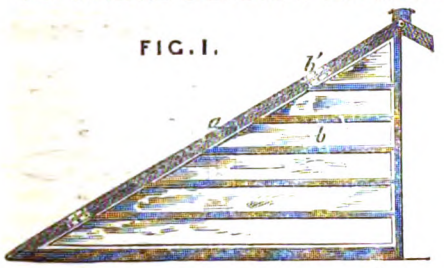

FIG. 2.

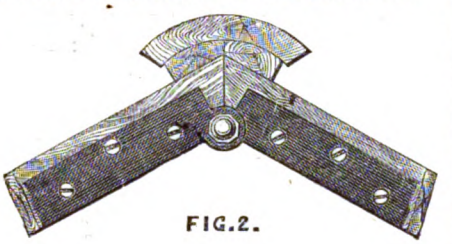

FIG. 4.

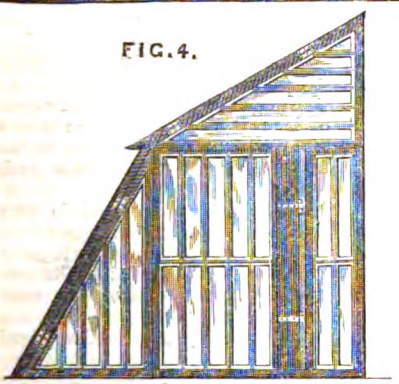

FIG. 3.

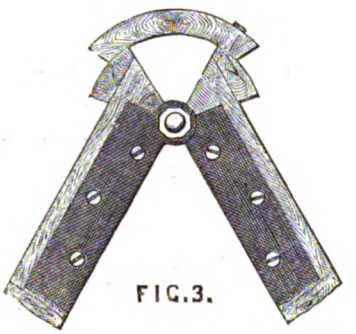

SIR JOSEPH PAXTON'S IMPROVED HORTICULTURAL BUILDINGS.

SIR JOSEPH PAXTON, M.P., who has probably as good a knowledge of the requirements of horticultural buildings as any man living, has patented a set of improvements in their construction. In carrying out his invention rectangular glazed frames are used, and are by preference longer than they are wide. These frames are combined in pairs at their upper ends by hinges, in such manner that their lower ends may be set apart at different times to a greater or less distance, according to the horticultural purposes to which the buildings are for the time applied, and their upper ends are so arranged as to form good ridges, where two of the frames go together. Each pair of such frames is confined with the neighbouring pair by distance pieces of a few inches in length, which are made to lock or hold the neighbouring pairs of frames correctly together, leaving an open space between; and it is by means of these openings that ventilation is obtained for the interior of the buildings. The openings are arranged to be covered, or for a time partly covered, by doors or flaps hung to the sides of the frames, such doors being by preference made to open or close in parts to facilitate the adjustment of the ventilation from time to time. The lower parts of the frames, when of wood, are shod with zinc, or other metal. In some cases, such frames as are above described are placed one above another, the upper ones forming a roof, and the lower ones forming inclined sides sustained by uprights. The ends of such buildings may be made of angular glazed frames, so arranged as to form different angular ends, or the ends may be made of wood, or of mats, or of other material.

Fig. 1 of the annexed engravings is an end view of one-half of a horticultural building or glazed structure constructed according to Sir Joseph's invention. *a a* are the side frames, which are hinged together at their upper ends, and are in this structure inclined at an angle of 30° to the ground line. *b b* are triangular glazed frames, forming the ends of the structure; they are hinged to the side-frames at *b' b'*. If it is desired, the side-frames may be inclined at an angle of 60° to the ground line, and the end frames, *b*, to adapt them to the change of inclination in the side-frames, may be turned one-quarter round. Fig. 2 is an end view of one of the joints employed to combine together in pairs the side-frames, *a a*. In this figure, the joint is in the position which it assumes in fig. 1. Fig. 3 is a similar view of the joint in the position it assumes when the side-frames are at an angle of 60° with each other.

The frames have each a metal eye fixed to them, and a thumb-screw passes through the eyes of the two frames, and screws into a nut beyond. Each frame has also a wooden block, with a curved upper surface fixed to its upper edge; and a curved ridge-piece is employed, which, resting on the curved blocks of the two frames of each pair, makes a tight joint at whatever inclination the frames may be set. The ridge-piece is held in position by pins at intervals.

Fig. 4 is an end view of one-half of a structure formed from the same frames, *a* and *b*, and in which frames, *a a*, are placed one above another, the upper ones forming the roof, and the lower ones the inclined sides. In this structure a fixed framework, *A A*, is employed, and the roof is fixed to this by screws, and the side-frames may be hinged to the upper part of the fixed frame-work, *A*, all round in a similar manner to that in which the frames *a* were before hinged together in pairs.

PRESS PERVERSION.—A paragraph which has lately gone the rounds of the press, presents a singular example of the perversions which, somehow or other, are effected by the press. At a late meeting of the Society of Arts Mr Scott Russell mentioned the "circuitous way" in which a copy of the Report on Naval Architecture was obtained. The paragraph says it was procured "from the continent!" It was not, however; and Mr. Russell did not state that it was.

LITERATURE.

The Carpenter and Joiner's Assistant; a complete course of Practical Instruction in Geometry, Geometrical Lines, Drawing, Projection and Prospective—the Selection, Preparation, and Strength of Materials, and the Mechanical Principles of Framing, with their Applications in Carpentry and Joinery. Parts 5.—14. Blackie and Son. Glasgow, Edinburgh, London, and New York.

WE have nothing but praise to give to this admirable work, which is now sufficiently far advanced in publication to enable us to speak of it with confidence. Its authors are equal to their work; its theoretical disquisitions being sound, and its practical articles full and reliable. Its illustrations are really perfect. We earnestly recommend it to carpenters, joiners, and other mechanics, and wish every trade possessed an equally splendid text book.

Painting Popularly explained, including Fresco, Tempera, Encaustic, Miniature, Oil, Mosaic, Water Colour, Missal, Painting on Pottery, Porcelain, Enamel, Glass, &c.; with Historica, Sketches of the Progress of Art. By THOMAL JOHN GULLICH, Painter, and JOHN TIMBSS F.S.A., Author of Curiosities of London, &c, Kent and Co. (late Boyne) Fleet-street.

THE work before us singularly bears out, in their utmost integrity, the promises made to the reader in its title. To a great deal that is original in thought, expressed in simple and not inelegant language, and free from technicalities, is added much ably condensed information from the best and most expensive volumes devoted to art. Mr. Timbs, admirable as a collator, is here conjoined with Mr. T. J. Gullich, an artist, whose pen exhibits a happy fluency of style, and occasionally a just severity of handling which, only requires a little less modest reserve to render his literary talents a most desirable aid in the detection and exposure of the cant which prevails at the present moment in art. As a means of reference, the careful index of the book before us will afford facilities to the connoisseur and general reader to an extent, the expectation of which, its comparatively small size at first appears to discourage; and the artist may learn in the volume all that description of knowledge, which books have the power to bestow—a history of art, with its mechanical resources and requisite paraphanalia; more than this, it would be absurd to expect.

We have to thank the author of the Year-Book of Facts, Popular Errors, Curiosities of Science, Curiosities of History and other excellent works of reference; and his co-adjutor, Mr. T. J. Gullich, for a volume which we hope to have the opportunity of often opening for our own information, and for the delectation of those for whom we write.

Adcock's Engineer's Pocket Book for the year 1859. London: Simpkin Marshall, and Co.

THIS book suffers, as usual, from the very comprehensiveness of the information contained in it. Without going over its valuable contents very minutely, we find that its articles are brought up to the end of last year, and are prepared with the accustomed care of its authors. We know of no book of the kind in which the information needful for engineers is, in the main, so sound or so complete. We observe, however, with much regret, that the absurdly blundering article on Naval Architecture—the defects of which were pointed out by us two years ago—still stands uncorrected even by an "Erratum."

A Short Handbook of the Comparative Philology of the English, Anglo-Saxon, Frisian, Flemish or Dutch, Low or Platt Dutch, High Dutch or German, Danish, Swedish, Icelandic, Latin, Italian, French, Spanish, and Portuguese Tongues. By HYDE CLARKE, D.C.L., London: John Weale, 59, High Holborn. 1859.

A LITTLE book on a great subject; but, though small, it contains more than any reader will thoroughly master, unless he bring considerable previous knowledge to its study. One important lesson it may, however, teach to every reader, viz., that between ages so widely different as to form the broadest barrier which can separate two peoples, there is a relation sufficiently intimate, and sufficiently apparent, to suggest the thought that all mankind belong to one great family, and that "God has made of one blood all the nations of men."

Five Place Logarithms, arranged by EDWARD SANG, F.R.S.E. William Blackwood and Sons. Edinburgh and London. 1859.

THIS little book is about four inches by three inches, and contains thirty pages of tables in a paper cover. It sells for 6d. This is all we observe on looking at it, and into it; and as the author has not chosen to say anything about it, we do not see why we should add more.

CRUSHING APPARATUS.—Mr. E. W. Blake, of Newhaven, has introduced a simple but useful form of crushing apparatus. It consists essentially of a pair of vertical jaws, one fixed, the other moveable; or both may be moveable. These jaws have their faces corrugated vertically, and convergent downwards, so that whilst the space at the top, where the stones, &c. are introduced is sufficiently large to receive them unbroken, the space at the bottom is only sufficient to allow the fragments to pass when broken to the required size. A short powerful vibration is imparted to one or both of the jaws by any convenient levers worked by a crank or eccentric. The back stroke of the jaw is effected by a spring. If one stroke does not crush the stones sufficiently the next will crush them still smaller, and so on until they are sufficiently reduced to pass through the bottom space between the jaws. It is also proposed to combine with this machine a revolving screen to receive the fragments as they fall from the jaws, and sort them into two or more sizes,

AN IMPROVED LATHE CHUCK, AND LATHE VICE.

I beg to forward for insertion in the MECHANICS' MAGAZINE, a drawing of two adjuncts to a lathe, which I have invented, and which I trust may prove interesting to some of your readers, who like myself, have suffered trials of patience, constantly occurring, for want of some such instruments.

The first is an universal chuck. I had turned my attention to it some years ago, and had put it on paper, when in a book called "Le Manuel du Tourner," I found, figured, precisely the same thing as I had *then* thought of; in that, the helical screw was on the part of the chuck which is screwed on to the mandril, and an objection was stated that the work was always jammed, and sometimes broken, by the force of the tool acting to turn the face-plate, and therefore force the "dogs" still tighter. This I then remedied by putting the helical screw on a loose face plate, fitting behind, and capable, as shown in the drawing, of turning on the true face-plate, which was screwed on to the mandril.

My profession calling me abroad, I had ceased to think of this, when at Pernambuco, in Brazil, I was surprised and pleased to see on an American lathe the identical chuck, acting, as the chief engineer assured me, most perfectly, and saving so much trouble even for factory work (it was in a factory attached to a cotton mill), that he would not be without it on any account. Adapted to it was also a vice (worked by the same helical screw), of which I have given a sketch at G., Fig. 3.

The second is a small lathe-vice, which for some purposes would be preferable to the one I have just spoken of.

I will now give an account of each, with reference to the drawings.

FIG. 1.

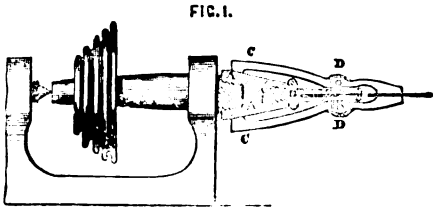

Fig. 1. A is a face-plate with four or more slots, in which move the dogs. B B are the dogs which gear in the helical screw. C helical screw worked on the face of D. D a plate which turns round by hand on the collar of A. E is a ring screwed on to D, and which keeps A and D in their relative positions. *a a*, portions of A, are the slots in which the dogs work.

For use, screw A on to the mandril; turn D till the dogs have receded far enough from the centre to embrace the work; now, by turning D back again the dogs will be forced to the centre, and hold the work firmly and truly centered at one operation.

The second is very simple, and will require but little explanation.

FIG. 2.

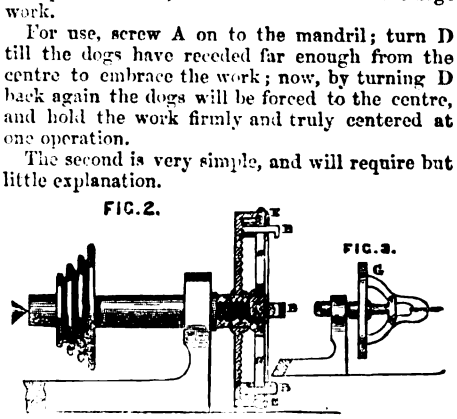

Fig. 2. A is a conical chuck screwing on to the mandril. As the screw B is turned into the collar D, in which the jaws are piveted at E E, the ends of the jaws C C, are forced asunder by it, and the work is held firmly by them, or *vice versâ*, it is released.

J. H. SELWYN, Capt. R.N.

NOTICES.

Numbers 1845 and 1846 of the MECHANICS' MAGAZINE (original series), containing the paper read at the Society of Arts, Dember 15, 1858, "ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWERS OF ATTACK AND DEFENCE," by one of the EDITORS of this Magazine, together with the discussion upon the same, are still on sale.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 6d. per line for any number of insertions less than 13; for 13 insertions, 5d. per line; and for 52 insertions, 4d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can be received after 9 o'clock on Friday morning for the ensuing number.

TO CORRESPONDENTS.

☞ The practice of publishing a vast quantity of fictitious Notices to Correspondents has become so general in cheap journals, that the public, who are not in the secret, have come to consider it the duty of Editors to answer any and every question that may be put to them by readers. This cannot, however, be done in a journal like our own without entailing an immense amount of labour (often of a very unnecessary character) upon us. We, therefore, beg most respectfully to decline the task. But in order that our correspondents may not be deprived of all advantage in this respect, we shall, as a rule, publish such queries as may be sent in good faith to us, though not such as appear to be sent merely for the sake of giving trouble. To the published queries other correspondents will, we hope, reply, and their replies shall likewise be published. By this arrangement we shall save ourselves much inconvenience, and at the same time secure, we trust, to our readers all the information they may desire. All questions must be stated simply, clearly, and without circumlocution of any kind; and we shall feel grateful to those correspondents who kindly take the trouble to send such information by way of reply as they may possess. Mere questions of business we shall of course answer ourselves; but whenever calculation, reference to published works, &c., are necessary, we shall dispose of the questions sent as stated above.

Erratum.—No. 1 (New Series) for Dec. 31st, 1858, p. 12, 1st. col., last line, *for* "liability," *read* "little liability."

STEAM BOILER FLUES.

A "PRACTICAL MAN," of much experience, writes:—

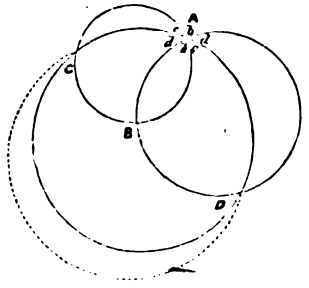
I have read, with much interest, the article in your new Magazine on "Improved Modes of Constructing the Flues of Steam Boilers," by W. Fairbairn, Esq., but one thing strikes me as contributing materially to the distortion of the flues in the boilers made for the North-Eastern division of the London and North-Western Railway, and that is, their being composed of plates only 3-8ths of an inch thick. I should be very sorry to place myself in antagonism to so eminent a man as Mr. Fairbairn, but my conviction is, that these boilers, from the outset, were constructed of too thin iron for the working pressure of 40lbs. to the square inch, and that had they been constructed of half-inch iron, the flues would not have become elliptical. I cannot detect any such distortion in my high pressure boiler flues, both the outer and inner shells of which are of half-inch iron, and the working pressure 40lbs. P.S.—I do not wish to be understood by the foregoing to deprecate the value of additional rings round a boiler flue, as anything that tends to additional safety must be valuable; but unscientific as I am, I should never have ordered of my boiler-maker boilers of that size, even work at a far less pressure, of less thickness than half-inch.

THE SPHERICAL EXCESS.

A VALUED correspondent, who is very favourably known to many of our readers, sends us the following interesting geometrical suggestion:—

GENTLEMEN,—I send you a little theorem, by the help of which it is easy to exhibit, geometrically, an angle on the sphere equal to half the spherical excess.

Let A B C D be four points on a sphere.



Through these points, three by three, let three circles be drawn, all intersecting in A:—viz., A B C, A C D, A D B. Then, in the curvilinear triangle (which is not, however, a spherical triangle), B C D, the sum of the three angles shall be equal to two right angles.

On reference to the figure, it will easily be seen that the angles B C D are severally equal to the angles *b c d*, and, therefore, that

$$B+C+D=b+c+d=\pi.$$

Euclid I, 32, is the stereographic projection of this theorem.

By making the radius of the sphere infinite, it appears evident that it holds *in plano*.

If A be the opposite pole to B, A B C and A B D will be great circles. Draw a great circle (dotted) through C D: then it is evident that the angles at C and D, which the great circle, C D, makes with the small circle, A C D, are each of them equal to half the spherical excess of the spherical triangle, B C D.

C. W. MERRIFIELD.

MISCELLANEOUS INTELLIGENCE.

PROPOSED DOCKS AT EAST GREENWICH.—An important project is now on foot for the formation of extensive dock accommodation at Greenwich, between that town and Woolwich, adjoining the Angerstein Branch of the South-Eastern Railway, and having entrances from the Thames at Greenwich on the west, and Charlton on the east. The site thus selected, from the peninsula form of the land, possesses remarkable advantages, offering facilities for the entry and departure of vessels similar to those afforded by the East and West India Docks, with the addition of a greater depth at low water, the entrances to consist of locks, 90 and 50 feet in width, which will be capable of taking in and floating larger vessels than any other docks upon the Thames. It is proposed to construct three docks in the first instance, comprising an area of about 48 acres of deep water, in addition to which land will be taken for quays, graving docks, warehouses, timber ponds, &c., the total length of frontage for dock quays being 9,200 feet. The cost of the docks is estimated at 500,000*l*., or 10,410*l*. per acre of water, whilst the West India Docks, containing 112 acres, cost 2,003,000*l*., or 17,884*l*. per acre; the St. Katherine Docks, containing 11 acres, cost 2,152,800*l*., or nearly 195,640*l*. per acre; the London Docks, containing 28 acres, cost 3,938.310*l*., or 140,654*l*. per acre, the latter company being now about to expend 700,000*l*. to obtain an additional dock space of about six acres. The Board of Directors of the South-Eastern Railway Company, appreciating the results likely to arise to the traffic of their line from the establishment of the proposed docks, have signified their approbation of the scheme, which their railway will connect with the counties of Kent, Surrey, and Sussex, and by the narrow guage junction at Reading, with the pottery and hardware districts, South Wales, and the western counties. It is proposed also to combine with the docks a steam-ferry, thus affording a connexion with the Blackwall Railway, and a convenient access to the docks for merchants and others from the eastern district of London.—*South London Journal*.

PORTSMOUTH DOCKYARD.—A great improvement has lately been made in the dockyard at Portsmouth. Gravel has been laid over the rough paving stones which from time immemorial have been the horror of all unhappy officers on "dock yard duty," especially those troubled with corns, or addicted to wearing tight boots. Another improvement cannot fail to strike one who may not have been dockyard visitors for some time; and this is the arrangement of the police, when the men are leaving the yard. In olden times, the police were stationed immediately at the gates, and it was impossible for them to exercise a proper amount of vigilance on the pushing crowd of men hurrying past them. Now they are stationed in open order, extending a considerable distance, and forming a lane through which the men have to pass in review, so that if a suspicious man should pass the scrutiny of the advanced policeman, it is almost impossible for him to escape the notice at the whole of the parts forming the lane. It is believed that this simple improvement will be the means of preventing much robbery of Government stores.

CHARCOAL.—H. S. Warner, Esq., of Trinidad, proposes to utilize the pitch of the celebrated lake in his neighbourhood. The deodorizing and purifying powers of different charcoals depend, he says, entirely upon the carbonaceous matter in them. But for such carbonaceous matter to act efficiently, it must be of a very porous nature, and as the pitch of the pitch lake of Trinidad does not contain such porous substance he merely uses it as affording carbonaceous matter, and he causes this carbonaceous matter to be diffused or spread through a substance which performs the same function as bone earth in animal charcoal. The substances found to answer this purpose are clay, pumice-stone, broken brick, spent animal charcoal, calcined bones, &c. There are several modes by which, from these materials, decolorizing and purifying charcoal can be made, one of which is as follows:—The pitch may be simply fused in a proper vessel, and when melted, the clay or other material may be added, it being in a dry state, and if necessary, previously crushed. The heat is then raised and continued as long as any valuable matter is given off by the pitch at a red heat. During this operation the materials should be kept stirred. The best proportions are three parts, by measure, of pitch powder to five or six parts of porous material.

MACHINERY FOR MAKING BOOTS AND SHOES.—Mr. Archibald Neilson, of Glasgow, has invented an improved apparatus for making boots and shoes. The main portion of the apparatus used consists of a shoe sole, the upper face of which is formed to a fine surface corresponding to the sole and heel to be moulded. This sole face is channelled all round the contour for receiving a corresponding frame of metal hinged at one end to the sole plate, and in pieces, if convenient. This frame has upon its upper face an angle or ledge piece for forming the seam at the junction of the sole with the upper of the boot or shoe, whilst its main inside edge face shapes the external contour of the sole edge. The workman takes the lasted boot, and having deposited solution or softened gutta-percha upon the face of the sole, he places the lasted "upper" down upon it, and then shuts down the open moulding frame. This at once moulds the sole, firmly attaches it to the edges of the lasted leather, and completes the operation. If required the heel portion may also have an open moulding frame.

CURRENT EVENTS IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

(COMPILED BY OUR OWN CORRESPONDENT.)

Fox and Henderson's Estate—Bilston Gas Company—Welsh and Newcastle Coals—Cunningham Sail Reefs—The Sunderland Merchants and the Timber Duty—Hand-Loom Silk Weavers and their Wages—The Leeds Town Council applying to Government—£5,000, a Donation—Society of Agriculture at Brussels—Deaths in Collieries—The Radcliffe Coal Proprietors—Fortnightly Payments—Important Mine Drainage.

THERE has been a meeting for audit and dividend on the separate estate of Sir Charles Fox, and for declaring dividend on the separate estate of Mr Henderson. Mr. Beale (of the firm of Beale and Marigold, solicitor to the assignees) said that on the separate estate of Sir Charles Fox there were assets amounting to £2,000, in the hands of the official assignee, and as his debts were only £1,800, this, after paying 20s. in the pound, would allow a small amount to go to the joint estate. The separate estate of Mr. Henderson showed a small amount in hand. When the sale had taken place there would be dividend.

The mains of the Bilston Gas-light Company have been considerably extended, as was shown by the report read at the anuual meeting on Monday last. The profits of the year are shown to be £2,125 1s. 11d., besides a balance of £114 9s. 5d. from the previous year's profits. The directors propose to make a general reduction in the price of gas at Lady-day next. Already they have remitted the annual charge of meter-rent.

The careful experiments, extending over several days, on the comparative evaporative power of Welsh and Newcastle steam coal, are at an end. The results will shortly be published.

All the new ships that are being built upon the Tyne and Wear, with one exception, are being fitted up with the self-reefing topsails, patented by Mr. Cunningham.

The Sunderland timber merchants, ship-builders, ship-owners, and ship-wrights have met, and resolved to petition the House of Commons for a total repeal of the timber duties. The existing Government restrictions gave a bonus on a Canadian vessel requiring 980 loads of timber in her construction, of £49 to the shipbuilder of St. John's and Quebec, over that of the ship-builder in this country. The same principle applied to foreign-built ships, and timber from foreign countries.

The hand-loom silk weavers at Middleton and Leigh are uniting to obtain an advance of wages. They allege that the manufacturers are ready to give them an advance of ½d. per yard.

The Town Council of Leeds have held a special meeting, and appointed a committee of their number to consider the propriety of presenting a memorial to Her Majesty's Government in favour of the establishment of bonded warehouses of Leeds. At the same meeting the council determined to petition the Queen in favour in making Leeds the assize town for the West Riding.

Lord Shaftesbury has received from a lady, whose name has not been communicated to the public, a donation of £5,000 for the improvement of dwellings of working men in Hull. All honour to her!

Bell's Weekly Messenger says:—"The Central Society of Agriculture at Brussels has resolved on holding an international meeting for the trial of reaping machines during the next year. The date is not yet fixed. A sum of 3,000 francs has been voted by the society, to be distributed in one or two prizes, and to defray the expenses connected with the carriage of the machines. We believe that an invitation to attend the meeting has been sent to all the leading implement makers in England."

Among the deaths in collieries since our last are ten, the result of two accidents, one in South Staffordshire, at the Osur Bod Colliery, near Bilston, where three men were killed from the breaking of the skip chain; and seven men and boys at the Agecroft Colliery, Pendlebury, in the north, by the snapping of the wire-rope by which the men are drawn up the shaft, occasioned by the over winding of the engine.

Messrs. Knowles and Hall, coal proprietors, Zadcliffe, have made an advance of one penny in the shilling to their men, to commence at once.

The South Staffordshire collieries have met in public meeting, advocating fortnightly instead of monthly payments, and the abolition of the truck system.

The "Deepfield Pond" has been once more pumped out of the mines in the neighbourhood of Deepfields, Bilston. Messrs. W. P. and W. H. Smith have, after a long struggle, been rewarded with success. They entered last summer into an agreement to pump the water out of the mines. The engine is computed to work to the power of 300 horses, discharging at every stroke 150 gals. of water, from a depth of 137 yards. The engine has made eight, and more frequently 9 strokes per minute. The water since 1834, has only been once pumped out of this mineral property, containing an area of upwards of 400 acres. This was in 1849, when the present engine wes erected and worked by a body of mine-owners, as the Union Engine Company. Since 1854, up to the present time, the mines of this district have been under water.

NOTES FROM THE EASTERN DISTRICTS.

(FROM OUR OWN CORRESPONDENT.)

The Gas Question at Norwich—The New Continental Telegraph—Gas at Holbeach—Drainage Works at West Haven—Newmarket Cemetery Works—The New Valley Drainage Commissioners and the Authorities of Wisbeach—Proposed New Corn Exchange at Norwich—Ipswich Railway Station—Norfolk Estuary Works.

THE Norwich Local Board of Health have had a long discussion in regard to the arrangements at present in existence for lighting the public lamps in that city. It seems that the British Gas Light Company, in whose hands the gas supply of the city is vested, require £4 per lamp per annum, while the Board are only willing to give £3 15s. The upshot of the matter is, that the Board have resolved to advertise for tenders for erecting lamps, &c.; to make all necessary arrangements for lighting, extinguishing, &c.; and to require the gas company to supply the lamps with gas in the manner prescribed in the 29th section of their act. The matter has been on hand since the summer.——Sir Charles Bright and Mr. Moseley, two of the principal officers of the British and Irish Magnetic Telegraph Company, have met a committee of the Norwich town council for the purpose of conferring with them in reference to the mode in which the wires of the land portion of the new telegraph, from the metropolis to Hanover, are to be carried through Norwich and its suburbs. Sir Charles Bright explained the course which the company wished to pursue in carrying the wires across the city and along the Newmarket-road; referring also to the difficulties incident to laying the wires underground from St. Stephen's-gates to Eaton-hill, as proposed by the committee. The chairman of the council committee informed Sir Charles that the residents in the neighbourhood of the Newmarket-road and the citizens generally were averse to posts and wires being placed along the road. Sir Charles replied that the directors of the company would not persist in a course likely to annoy the inhabitants, and would carry the wires from Hellesdon-gate along the bye roads over Hellesdon-bridge, and thence to Eaton, as first contemplated, having a communication across the city from Exchange-street to Hellesdon. The line from Norwich to Cromer (where the cable leaves the coast for Emden, Hanover) is in operation, and messages are now transmitted to the continent by the new route, over which it is estimated that 40,000 telegrams will be dispatched annually.——It is rumoured that a new gas company will be organised shortly at Holbeach, Lincolnshire. The rates charged at present are 7s. 6d. per 1,000 cubic feet, while at Boston, 16 miles distant, the charge is only 3s. 6d. ——The tender of Mr. Mortar, of Stratford, for sewerage works, proposed to be carried out by the West Ham Local Board of Health, has been accepted by the board. The amount of Mr. Mortar's tender is £16,379 15s. 11d.——The Newmarket Burial Board have accepted the tender of Messrs. Westley for their cemetery buildings—two chapels, entrance lodge, boundary walls and gates; the amount of the contract is £951.——Certain dams placed in the Nene at Waldersea and Guyhorn, are considered by the authorities of Wisbeach to injure the navigation and trade of that port; and a special meeting of the Nene Valley Drainage Commission has been held to consider a notice from the Wisbeach town council in reference to their removal. Mr. Stevens moved, and the Mayor of Wisbeach seconded, a resolution to the effect that the dams should be removed under the superintendence of Mr. Fowler, the engineer to the commission, the middle opening of Waldersea dam to be first removed, and if this course were attended with no ill effect, the other part to follow; the same course to be afterwards adopted at Guyhorn, and the dams to be closed again if any evils resulted from the more free course of the waters. On the votes being taken the only commissioners in favour of the motion were found to be the proposer and seconder. Mr. Fowler stated that if the local magistrate should be induced to make an order for the removal of the dams which have been placed in the river on the advice of eminent engineers, he should recommend the commissioners to disobey it, and even if a mandamus were issued, the same course would be advisable. He should require £2,000 for strengthening the Waldersea dam.——An effort is being made at Norwich to promote the erection of a new corn exchange, with an area of 12,000 square feet. It is proposed to erect the new building upon the site occupied by the present Exchange (which has an area of 7,000 square feet) and some of the adjoining premises. The cost of site and buildings is estimated at £23,000, and towards this sum £14,000 has been furnished in shares and donations. When this sum is increased to £20,000, the provisional directors will proceed with the undertaking.——A new railway station is progressing at Ipswich on the north side of the Stoke tunnel (Eastern Union Railway), the brickwork having been raised a few feet from the ground. Anent this station hangs a tale. Mr. Bruff, C.E., states to the Ipswich paving and lighting committee that the station will be used in two or three months whether it is completely finished or not. There have been, it is said, parties in the town making calculations for a station to be built by the Eastern Counties Company; but Mr. Bruff stigmatises this as merely a "vexatious proceeding." The Eastern Union Company will finish the station at present in hand, and place it at the disposal of the Eastern Counties Company. If that company refuse to use it, Mr. Bruff believes that the Board of Trade will interfere when the East Suffolk system is opened, as all the traffic, he thinks, cannot be safely worked at the present station (which was erected nine years ago merely as a temporary expedient, but has been in use ever since). It would occupy too much space to enter into all the circumstances of this affair, but it will be seen that the nominally-united Eastern Counties and Eastern Union Companies are not working very harmoniously.——It is understood that the Norfolk Estuary works are suspended for the present.

GLYCERINE MANUFACTURE.—An important improvement in the manufacture of glycerine has been patented by Mr. Reynolds, an experienced chemist, King William-street, London-bridge. It chiefly consists in blowing dry steam at a temperature of about 400° Fahr. through spent soap lees. By this means the glycerine is evaporated, and the salts are left to deposit themselves in the containing vessel.

METAL AND COAL TRADES, &c.

(FROM OUR OWN CORRESPONDENT.)

The Mills, Forges, &c. of South Staffordshire—The Blast Furnaces—New Furnaces—A Contract—Pig Iron per ton—The Coal and Ironstone—Hematite Ore—The Furnaces in blast in Scotland—The manufacture of Pig in Scotland—The Stocks—The Glasgow Market—The state of the Iron and Coal Trades in Yorkshire, &c.—The demand for Railway Ironwork—The Sheepbridge blast furnaces—Employment—Activity of the Coal trade—Employment in Yorkshire, Derbyshire, and Lancashire—Sheffield, Birmingham, and Wolverhampton trades—The Hollow-ware trade—Cut nail trade—Tin Plate and Japan markets—The Lock trade—Walsall—Saddlery—The prices of 1842—The Woollen market at Leeds—Ditto at Bradford—Leicester machinery—Kidderminster trade.

THE mills and forges in South Staffordshire are in fair operation, the leading markets being tolerably busy. It is also stated that amongst the Iron Founders and machinists of the district there is more doing, and that employment is on the increase.

At present there are 133 blast furnaces in the district in operation, and about 50 out of blast.

Three new furnaces have been completed, and two others are nearly finished. Contrasted with the period immediately before the late crisis, Sept. 1857, there are now 25 blast furnaces less in operation than at that time.

Good hot blast mine pig iron is realising £3 15s. per ton, and cold blast, £4 5s.

The coal trade continues brisk, and the rates are well maintained. Ironstone, the yield of the district, is in good demand, and prices have an upward tendency. In fact, sales have been effected at from 1s. to 1s. 3d. advance.

Large quantities of hematite ore are coming into the district, and higher rates are obtained.

The furnaces now in blast in Scotland are 132, and there are 45 not working. The total quantity of pig iron made in 1858 in Scotland, was 945,000 tons, which, at the average price of the year, represents a total value of £2,554,000. The stocks, which are now 295,000 tons in warehouse keepers and makers stores, have increased 135,000 tons in the year. The market in Glasgow was weaker on Tuesday, and a large business was done at 54s. cash, and proportionate open rates. No. 1, G.M.B., 53s.; No. 3, G.M.B., 53s.

The reports of the state of the iron and coal trades in Derbyshire, Yorkshire, and Lancashire, state that orders for the Continent are more plentiful, whilst the demand for the home consumption continued to increase. The demand for rails and railway ironwork is on the increase. The three new blast furnaces which have recently been erected by the Dunstan and Barlow Company at Sheepbridge, near Chesterfield, will be blown in during the ensuing month. Additional furnaces are about to be erected, all of which will afford employment for a large number of hands. The coal trade continues to increase in activity, and the demand is exceedingly brisk. The West Staveley Colliery at Whittington has been recommenced, and employment for colliers abounds everywhere in the three counties.

In the Sheffield trades a decided improvement is perceptible on every hand. Respecting the trades of Birmingham and Wolverhampton, it may be reported that the majority of manufacturers have sufficient orders on hand to keep them fairly employed. The hollow-ware trade, which has been extremely depressed during the year, shows some symptoms of improvement. In the cut nail trade the different manufacturers are tolerably busy. Tin plate and japan workers are in full work, with every prospect of a continuance. In the lock trade there has been a decided improvement in all its branches during the past fortnight, and some of the larger manufacturers have been working overtime. Walsall has suffered least from a general depression in trade, military orders for saddlery having compensated to a considerable extent for the falling off in the general demand.

The reports from the manufacturing districts continue to be decidedly favourable. At no period since the great turn out of 1842, which lasted for eight weeks, have stocks of goods been so bare at Manchester.

The reports from the woollen districts are also very favourable; at Leeds, the opening market of the year was of a very satisfactory character. The report from Bradford is, that the transactions in English wools have been on an extensive scale, with an upward tendency in prices. In the trade of Leicester, there is now a greater quantity of machinery employed than was ever before known. A wonderful change for the better has taken place in the trade of Kidderminster.

PROVISIONAL PROTECTIONS.

Dated December 6, 1858.

2788, J. G. Arnold, of Worcester. Improvements in envelopes for letters and similar purposes.

2790. J. Muir, of Glasgow, Pattern Designer, and F. Muir, of Paisley, Pattern Printer. Improvements in ornamental or colour printing.

2792. J. Dawson, of Holbeck, Leeds, Machine Maker. Improvements in machinery or apparatus for raising the nap on woollen cloths.

2794. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in the manufacture of gloves.—A communication from Messrs. A. and L. Fontaine, of Paris.

2796. E. W. Seale, of Merthyr Tydvil, Agent. Improvements in railway and other breaks.

Dated December 7, 1858.

2798. W. A. Gilbee, of South-st., Finsbury. An improved portable bath.—A communication.

2800. J. Whiteley, of Halifax, Machine Maker, and T. Kitchenman, of the same place, Stuff Presser. Improvements in press plates or apparatus employed in hotpressing woven fabrics.

2802. J. J. Harris, of Woodlesford, near Leeds, Brewer. Improvements in apparatus for refrigerating and regulating the temperature in worts and beer, which may also be employed as condensers in distilling.

2806. W. Burness, of Brixton. Improvements in pumping and forcing liquids.

2808. J. Ferrabee, of Stroud, Engineer, and F. H. England, of Stroud, Manager. Improvements applicable to machinery for carding, scribbling, and condensing wool and other fibrous substances.

Dated December 8, 1858.

2810. G. F. Chantrell, of Liverpool, Furnace Engineer. Improvements in apparatus applicable to the manufacture and revivification of animal or vegetable charcoal.

2812. R. L. P. Manning, of Princes-sq., Mariner. A floating paddle wheel.

2814. S. Phillips, of Moseley, near Birmingham, Gentleman. Improvements in sliding window sashes, shutters, and doors.

2816. W. King, jun., of Guildford, Grocer and Tea Dealer. Improvements in apparatus for roasting coffee and other substances.

2818. H. Meidinger, of Heidelberg, Germany. Improvements in electric batteries.

Dated December 9, 1858.

2820. J. Barrow, Jun., of Manchester, Manufacturing Chemist. Improvements in the treatment of coal gas tar, and of the oils obtained by the distillation of the same, and for the application of substances obtained thereby.

2822. J. Eccles, of Blackburn, Cotton Manufacturer. Improvements in arrangements and machinery for preparing for manufacture and for manufacturing clay and other plastic earths into bricks, tiles, pipes, and other articles formed of such materials.

2824. J. Little, of Glasgow, Ironmonger. Improvements in fire grates and heating apparatus.

2826. J. Stewart, of Tottenham-court-rd. Improvements in the construction of the action of piano-fortes.

2828. J. Wilson, of Wansford, Northamptonshire. Improvements in machinery for tilling and cultivating land.

Dated December 10, 1858.

2830. J. Flockton, jun., of Manchester, Engineer. Improvements in stop or reversing taps.

2836. A. Barclay, of Kilmarnock, Engineer. Improvements in obtaining motive power by means of electricity, magnetism, and electro-magnetism.

2838. W. Beardmore, of Deptford, Engineer. Improvements in steam boilers.

2840. G. W. B. Kiallmark, of Bridgewater, Somerset, and W. T. Timewell, of Paddington. Improvements in the manufacture of cements.

Dated December 11, 1858.

2842. J. B. Guthrie, of Manchester, Warehouseman. Improvements in the manufacture of India-rubber overshoes.

2844. J. Hinks, of Birmingham, Manufacturer. Improvements in ships' and other lamps.

2846. C. J. Richardson, of Kensington-square, Architect. Improvements in apparatus to be applied to chimneys or flues of buildings, for economising heat and reducing the quantity of smoke passing into the atmosphere.

2848. W. E. Wiley, Pencil Maker, of Birmingham. Improvements in ever-pointed pencils.

Dated December 13, 1858.

2850. J. A. Carruthers, Reed Maker, and T. Blackburn, Mechanic, both of Blackburn. Improvements in apparatus for guiding and regulating the warp threads in the operations of warping, tape-sizing, looming, and weaving.

2851. R. Whittam, of Accrington, Engraver. Improvements in machinery or apparatus, for tracing designs from an engraved roller, or from an engraver's sketch upon steel or other metallic surfaces, used as dies by engravers to calico printers.

2852. L. C. V. Yon, of Lisieux, France, Upholsterer. Improved elastic beds.

2853. J. M. Rousset, of Belleville, Paris, Mechanician. A new system and new apparatus, using air as a motive power.

2854. J. E. Boyd, of Lewisham, Gentleman. Improvements in candlesticks, lamps and lanthorns.

2855. R. A. Brooman, of 166 Fleet-street, London, Patent Agent. Improvements in twisting and otherwise operating upon threads, twine, or cords, and in apparatus for performing the same. A communication from Messrs. Edmond Empis and Co., of Wazemmes, France.

2856. R. A. Brooman, of 166 Fleet-street, London, Patent Agent. Improvements in the manufacture of cranked axles and shafts. A communication from Messrs. Rousery, Lacombe, and Co., of Rive de Gier, France.

2857. E. Loomes, of Whittlesea, Cambridge, Farmer. An improvement in the construction of steam engines.

2858. J. Ferrabee, of Stroud, Engineer. Improvements in the construction of steam engines, and in the mode of working the same.

Dated December 14, 1858.

2859. J. Webster, of Birmingham, Engineer. A new or improved method of recovering copper and zinc from liquids, which have been employed to dip or pickle articles made of brass or other alloys containing copper and zinc.

2860. E. Bow, of Port Dundas, Coalmaster. Improvements in pumps.

2861. D. Anderson, of Glasgow, Ironmonger. Improvements in taps or valves.

2862. J. Wade, of Bradford, York, Manufacturer. Improvements in means or apparatus employed in weaving.

2863. G. Baker, of Woburn, Bedford, Farm Steward. An improved construction of manger fastening.

2864. R. A. Brooman, of 166 Fleet-street, London, Editor of the MECHANICS' MAGAZINE and Patent Agent. An improvement in transmitting electric telegraph signals. A communication from T. A. M. Sortais, of Lisieux, France.

2865. J. T. Smets, of Placamen, France, Distiller. A method of making vinegar from a refuse product obtained in the manufacture of starch.

2866. F. Jossa, of Bishop Auckland, Chemist. Improvements in furnaces for generating steam and other purposes.

Dated December 15, 1858,

2867. J. Pendlebury, of Crumpsall, Bleacher. Certain improvements in machinery or apparatus for bleaching or cleansing textile fabrics or materials.

2868. D. Rowan, of Greenock, Engineer. Improvements in steam engines.

2869. H. Bridges, of Bridgewater, Carriage Builder. Improvements in the means of working breaks on carriages on railways.

2870. F. C. N. J. Migeon, of Morvillars, France, Manufacturer. Improvements in manufacturing screws, rivets, nails, spikes, and all similar articles made of metallic wire, and in the machines connected therewith.

2871. A. V. Newton, of Chancery-lane. Improved machinery for manufacturing bullets. A communication.

2872. A. V. Newton, of Chancery-lane. An improved arrangement of condensing apparatus. A communication.

2873. J. Bullough, of Blackburn, Manager. Improvements in looms.

2874. C. F. Vasserot, of Essex-street, Strand. An improved pendulum governor for regulating the supply of steam to the cylinders of marine engines. A communication from M. Billotet, of Marseilles.

2875. W. Clark, of Chancery-lane. Improved agricultural implements.—A communication from L. J. Chateau, of Paris.

2876. J. Wardill, of Commercial-road East, Engineer. An improved stopper or controller, to stop and control the running out of chains and ropes.

2877. G. Bell, of Wandsworth, Gentleman. An improvement in matches and fuses.

2878. T. Moss, of Gainsford-st., Islington. Improvements in printing bank notes, bills of exchange, and other documents requiring like security against being copied.

2879. W. Morgan, of Witton-park Iron Works, near Darlington. Improvements in the manufacture of iron.

Dated December 16, 1858.

2881. W. H. Carmont, and W. Corbett, of Manchester, Iron Manufacturers. An improved mode of constructing furnaces for the production of wrought iron and steel, and manufacturing such metals into ingots and other forms.

2882. A. and J. Stokes, of Birmingham, Manufacturers. New or improved machinery for the manufacture of screws.

2883. R. Mushet, of Coleford, Gloucester, Metallurgist. A new or improved manufacture of cast steel.

2885. J. W. Edge, of Manchester, Gun Maker. A certain improvement in balls, bullets, or other projectiles to be employed in fire arms or ordnance.

2886. J. W. Friend, of Freemantle, Southampton, Watch Maker. Improved apparatus for ascertaining and registering the depth and flow of liquids and the distances run by ships at sea.

2887. A. Mackenzie, of Glasgow, Mechanist. Improvements in sewing machines.

2888. J. J. Marquis, of Paris, Civil Engineer. Improvements in galvanic batteries.

2889. W. White, and J. Parlby, of Great Marylebone-st., Architectural Decorators. Improvements in the preparation or treatment of "carton pierre," and such like com-

Digitized by Google

position, and in the application thereof to the coating or covering of walls and other surfaces.

2890. R. A. Brooman, of 166, Fleet-st., London, Editor of the "Mechanics' Magazine" and Patent Agent. An improvement in plating and gilding forks, spoons and other metal articles.—A communication from Messrs. De Sauvigny, of Paris.

2891. W. Clark, of Chancery-lane. Improvements in submarine electric telegraph cables or conductors.—A communication from F. M. Baudouin, of Paris.

Dated December 17, 1858.

2892. J. J. Aston, of the Middle Temple, Barrister-at-Law. Improvements in machinery or propellers applicable for the propulsion of ships boats and other vessels on and through the water, and in the propelling of all such vessels on and through the water by means of such propellers.

2893. W. J. Johnson, of Manchester, Manager. Improvements in machinery or apparatus for preparing for joining the rails of railways.

2894. J. and J. Inshaw, of Birmingham, Engineers. An improvement or improvements in locomotive engines.

2895. A. Hinde, of Wolverhampton, Manager. Improvements in treating or preparing the cinder or slag from puddling furnaces for the purpose of facilitating the manufacture of iron therefrom.

2896. J. Kerr, of Bedford-terrace, Southwark, Engineer. Improvements in the construction of revolving fire-arms.

2897. J. Clegg, of Keighley, Engineer. Improvements in lubricating the valves and pistons of steam engines.

Dated December 18, 1858.

2899. J. Aitken, of Edenfield, near Bury, Manufacturer, and J. Brooks, of the same place, Overlooker. Improvements in looms.

2901. A. Mitchell, of Glasgow, Machinist. Improved apparatus for registering the speed of engines and other machinery.

2903. A. P. How, of Mark-lane, Engineer. Improvements in cocks or stop valves.

2905. J. Soutter, of Edinburgh, Turner. Improvements in apparatus for drying or airing linen or other articles of wearing apparel.

Dated December 20, 1858.

2907. T. S. Woodcock, of Salford. An improved index or book and paper marker.—A communication from J. Johnson.

2909. R. Maclehouse, of Ayr, Bookseller. Improvements in stereoscopes.

2911. A. V. Newton, of Chancery-lane. An improvement in lanterns.—A communication.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated December 27, 1858.

2953. M. A. Mennons, of Paris. An improved composition for the protection of certain metallic surfaces.—A communication.

2975. J. Shaw, of Manchester, Mechanic. A new mechanical combination, called an indefinite feed movement.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1896. P. Spence. Alum.
1897. J. L. Piggett. Syringe.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this magazine from official copies supplied by the Government, and are therefore the property of the proprietors of the Magazine. Other papers are hereby warned not to produce them without acknowledgment.

STEAM ENGINES, &c., 969, 973, 976, 989, 995.

BOILERS AND THEIR FURNACES, 979, 988.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 978, 997, 1004.

SHIPS AND BOATS, including their fittings, *None.*

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 975.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 980, 1001.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 967, 970, 981, 984, 998, 1000, 1012.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 992.

LIGHTING, HEATING, AND VENTILATING, 985, 99

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 966. 990, 991, 994, 1008, 1010.

METALS, including apparatus for their manufacture, 971, 983, 1006.

CHEMISTRY AND PHOTOGRAPHY, 977, 981, 1013.

ELECTRICAL APPARATUS, 986, 1002.

WARFARE. *None.*

LETTER PRESS PRINTING &c., *None.*

MISCELLANEOUS, 968, 972, 974, 977, 982, 987, 993, 995. 996, 997, 999, 1003, 1005, 1007, 1009, 1011.

966. J. C. FAUCON. *Improvements in bedsteads, bed bottoms, seats, and articles for lying and reclining on.* Dated April 30, 1858.

Elasticity is here obtained by forming the part on which the mattress, cushion, &c., is to be placed, of a trellis, lattice, or framework, resting on strips or bands of steel curved into a peculiar stirrup-like shape, and so connected at their lower ends to the frame of the bedstead or seat, that they may be removed or folded down when not in use. At top they are attached to the trellis by forming them with a slot into which a key or pin takes. *Patent abandoned.*

967. J. CHAPMAN, Jun. *Producing a substance entitle felted woody-fibre, convertible into useful articles, and applicable to the internal fittings and decorations of dwelling houses.* Dated April 30, 1858.

Here the woody-fibre which the roots, leaves, and stems of all vegetables (including weeds) contain, is separated from the mucilaginous parts by trituration, washing, rinsing, boiling, dyeing various colours, pressing and drying. The woody-fibre is thus produced in a hard, compact felted state. *Patent abandoned.*

968. G. H. ELLIS. *Improvements in cleaning boots and shoes by machinery, and an apparatus for the same, and which is also applicable to cleaning other articles in domestic use.* Dated April 30, 1858.

This invention consists in mounting brushes or other surfaces on springs, levers, slides, or other parts, and imparting thereto reciprocating motion for cleaning boots, shoes, and plate, or plated articles by machinery. *Patent completed.*

969. W. CLARK. *Improvements in obtaining motive power, and in the apparatus connected therewith.* (A communication.) Dated April 30, 1858.

This invention is not described apart from the patentee's drawings. The following is a literal copy of the patentee's first claim:—"First, using as motive power the gases resulting from the combustion, and from the air which produced the same, these gases being by said combustion increased with heated air, or with vaporised steam—this being done by the means hereinbefore described, and further specified in the following claims." This is followed by other strange claims, such as "producing the said motive power by the combustion of known fuels in closed fire-places without grates; also the faculty of regulating the vaporisation, the temperature, and the combustion in its various stages, according to the nature of the fuel employed, and of changing the proportions of the motive mixture,"—vaporising the water employed by its projection in a subdivided state "in the gaseous current resulting from the combustion, or in the fuel in ignition,"—introducing the air into the fire-place from "three parts or regions," viz., underneath the fuel, above it, and "in the current after the combustion"—"introducing the water injected in the blowing cylinder during the aspiration or compression of the air, or it may be during both states of action of the blowing engine," to prevent the heating of this air, to diminish the force of the current of air going to the fire places, &c., and specially to lubricate the friction surfaces in contact with the burnt air. *Patent completed.*

970. P. A. GODEFROY, P.A. *Improvements in the mode of separating vegetables from animal fibres or fabrics.* Dated April 30, 1858.

This invention consists, 1, in a process for decomposing and separating cotton or other vegetable matter. The inventor submits the fabrics to a heated solution of acid to decompose in part the vegetable matter. 2. When the fabrics are taken out and well rinsed, they are consigned to a steam jacket boiler, (recommended to be egg-shaped,) having a perpendicular shaft in its centre, with arms attached, and driving gear to give it motion. The fabrics (wrung as dry as possible after the above process) are placed in the boiler, and kept in perpetual motion whilst under treatment by the armed shaft aforesaid. The steam is then allowed to escape by a tap in the boiler, and the fabrics are left in the open boiler to dry. When dried, they are taken out and subjected to the action of a winnowing machine, which completely removes all vegetable dust from the animal matter. This finishes the operation. The next part is a process to decompose and separate wool in connexion with vegetable matter. 1. When a highly bleached article is desired, he submits the vegetable and animal substances to a solution of potash or soda, and stock-washes them well. When thoroughly rinsed they are passed through a weak solution of sulphuric acid and water, and again well rinsed. Then he charges the boiler with chloride of lime and potash, of sufficient strength for decomposition of the animal matter, which takes place by immersion of the fabrics in this compound. When removed from the boiler the fabrics are to be well rinsed, then dried for use. When not required to be very white they may be submitted at once to the boiler containing caustic lime, caustic potash, or caustic soda. 2. A boiler without a jacket will serve, but should have a shaft, &c., as in the jacketed boiler. *Patent abandoned.*

971. C. A. J. DEMANET. *The extraction of coals and minerals from mines.* Dated April 30, 1858.

Two strong iron screws extend from the bottom of the shaft, (where they turn in steps) up to the surface of the ground, where their upper extremities are set in bearings in a head frame, and are provided with pinions taking into a large toothed wheel mounted between them on the shaft of a horizontal wheel, which is driven by a crank rod actuated by a steam engine. The two screws thus have rotary motion communicated to them in the same direction. Upon these screws are mounted two platforms provided at each of their extremities with a strong female screw, through which the long vertical male screw passes. The platforms form the top and bottom of a cage, which may be divided into several compartments horizontally, upon which are to be placed the trucks or boxes containing the minerals. On rotary motion being imparted to the screws in one direction, the cage will be raised with its charge, and *vice versâ*. *Patent abandoned.*

972. J. H. JOHNSON. *Improvements in suspension bridges.* (A communication.) Dated April 30, 1858.

Here the suspending chains are rendered rigid by the application thereto of diagonal braces. Two or more chains are suspended on each side of the bridge, at different elevations, so as to form concentric curves, and the intervening spaces are occupied by the diagonal braces referred to, which are connected at each end by pins or bolts, to the upper and lower chain, and are so arranged as to subdivide the space between the chains into a succession of triangles having their apices alternately above and below, whilst the hypothenuse of each angle is formed by the corresponding link of the upper or lower chain, as the case may be. The links of the lower chain should be, of course,

Digitized by Google

of a greater length then those of the upper chain, to allow for the greater radius of its curve. *Patent completed.*

973. A. SMITH. *Improvements in valves.* Dated April 30, 1858.

The improved valve under one arrangement is made of brass telescope tubing. The valvular apparatus (for a horizontal pipe) consists of a vertical piece of tubing with a branch diverging from each side, through which the steam or liquid passes. The passage is shut off by a cylindrical valve within the central vertical part. This valve consists of a piece of spring tubing cut through longitudinally. The vertical tube is closed at its ends by metal plates, but in the upper plate there is a small aperture for the tubular valve rod. This rod passes through a stuffing box at the upper part of the valve casing, and its inner end is connected to a piece of metal which is soldered to the internal surface of the valve. A knob or handle is fitted to the outer end of the valve rod; upon pressing this knob the cylindrical valve slides down, and closes the steam or liquid passage. In this arrangement the entire area of the pipe is open to the passage of steam or liquid, the valve offering no obstruction to the flow of it. *Patent completed.*

974. J. PHYMONT.—*Improvements in apparatus for catching fish in tidal rivers and other watercourses.* Dated May 1, 1858.

The inventor digs a trench (which may be lined) in the bed of a tidal river. He places over the trough a cover extending beyond the sides of the trough, to partially shut out the light. He raises the cover by cross bearings to allow the water to flow under, and the fish to secrete themselves within the trough. When necessary he places bait in the trough. When required, he places along the sides of the trough, against the apertures, a lattice (say, of wire) so hung as to raise and fall and close the aperture against the egress of the fish. After every tide he raises the cover, and with a landing net takes out the fish. *Patent abandoned.*

975. R. WARDELL.—*Improvements in reaping machines.* Dated May 1, 1858.

This relates to a former patent, dated 1st Oct. 1857, and consists, 1, in a mode of transmitting motion to the conical endless belt or travelling platform (on which the corn or other grain is conducted after it is cut). 2, in a mode of connecting the knives or cutting blades to the machine for reducing the friction thereof, whilst they are being moved laterally. This is effected by supporting and guiding the bar to which the knives are affixed between anti-friction rollers. 3. In a mode of transmitting motion to the delivery rollers employed for keeping up the heads of the corn or other grain. 4. In a self-acting tilting platform, in lieu of rotating sheaf-delivery prongs. The invention is not described apart from the inventor's drawings. *Patent completed.*

976. R. ILLINGWORTH.—*Improvements in safety-valves.* Dated May 1, 1858.

This invention is not clearly described apart from the inventor's drawings. It may be stated, however, that it consists of a valve so constructed that the outlet afforded to the steam increases as the steam pressure is increased. Also of a water-indicating valve, which may be used either with or without the improved safety-valve, and which is so arranged as to give signals should the water get either too high or too low in the boiler, and so as to let all steam escape should its pressure get dangerously high. *Patent completed.*

977. W. SPENCE. *Improvements in the production and application of a material called French purple, and in the process employed in obtaining it.* (A communication.) Dated May 1, 1858.

This consists in the preparation of raw colour-producing acids from a mixture of "evernic, lecanoric, orsellic, erythric acids," &c. 2. In "the change that is produced on these acids by the combined action of ammonia, air, and heat, and their transformation into colouring matter." 3. In treatment by means of which the colouring matter is brought into a solid state. *Patent completed.*

978. L. TALABOT. *Improvements in rolling railway and other bars.* Dated May 1, 1858.

In rolling bars when what are called "three high rolls" are employed, the middle roll is formed, according to this invention, with alternate groves and projections—the projections on the middle roll enter into groves in the lowest roll, and the projections on the highest roll enter into groves in the middle roll. The metal is passed alternately through the spaces between the middle and upper, and the middle and lower rolls. Thus the spaces through which the metal is passed are always enclosed, except when passing a railway bar for the last time through the rolls, when in order to round off the top of the rail, the space between the rails is inclosed by groves in each roll. The distance between the rolls are adjusted by wedges acted on by screws, and placed between the bearings. The bar coming from the lowest groves is raised by a lever suspended from the axis of a wheel which runs on a rail above the rolls. The rail is connected with levers so that it may be raised and lowered. The bar may thus be moved sideways, as well as raised and lowered. In rolling round bars, the bars are rolled in the way now used, only in place of finishing the bars by rolling with guides, which makes it necessary to turn the bar quarter round between each passage, the bar is finished (after first drawing it down without guides, and then rolling it with guides) by again rolling without guides, the bar being turned to a greater or less degree between each passage under the rolls, according to the judgment of the roller. *Patent completed.*

979. W. HOPKINSON, and J. DEWHURST. *Improvements in apparatus for consuming smoke.* Dated, May 1, 1858.

Here the furnace is divided longitudinally in the middle, but the partition does not come to the front, a space being left for the smoke, &c., to pass from one compartment over the well-ignited fuel in the other compartment. At the back of the furnace, or in the bridge, there are two dampers, each capable of closing one compartment, and each actuated by a bell crank and rods. Previous to feeding either compartment with coal, its damper is raised to close the back of the furnace, that all the products may pass to the front, and then over the fire in the other compartment. The novelty here consists in the peculiar combination of apparatus above described. *Patent completed.*

980. F. M. GREGORY. *Improvements in chaff-cutting machines.* Dated May 1, 1858.

The Inventor proposes:—1st. to employ a cylindrical frame provided with a disc at each end, through the centre of which he passes horizontally a shaft, which carries at its end a fly-wheel, the whole being mounted on a framing. Upon the outer periphery of the discs, and attached to the framing, he places two knives diagonally, so that the first end of one of the knives begins to cut at the moment the last end of the second knife has completed half a revolution of the cylindrical frame. 2nd. He employs, in combination with the cylindrical frame, two sets of rollers actuated by bevelled and multiplying wheels to regulate the length of the substances to be cut. He also employs a clutch affixed to the bevelled wheel shaft to throw the same in or out of gear while the knives are in motion. The mouth of the box or tray is curved in order to take the circular motion of the knives. *Patent abandoned.*

981. J. A. HARTMAN. *Improvements in preparing and combining colours for printing cotton cloth.* Dated May 3, 1858.

This relates to producing purple or violet colours on cotton cloth from the colouring matter of madder by the steaming or vaporising process, and it consists in using an organic volatile acid, by preference acetic acid, with a salt of iron as a solvent for, and as a means of fixing the colouring matter of madder used to produce the said purple or violet colours. *Patent completed.*

982. C. SCHLEICHER. *An improved machine intended to make the points of needles, pins, and all other similar articles.* Dated May 3, 1858.

This consists in an apparatus to take the place of the hand in making the points of needles, pins, and similar articles. The apparatus is not described apart from the inventor's drawings. *Patent completed.*

983. S. ETCHELLS, A. CONSTELDINE, and S. CATTELL. *A reversing water tube iron, to work with single blast or double blast, as occasion may require, and an arrangement of water tube irons and parts connected therewith.* Dated May 3, 1858.

This consists of a reversing tube iron to work with single or double blast, and an arrangement of water tube irons and parts connected therewith to be used for a smiths' forge, hearths, or furnaces. A reversing water tube iron fixed horizontally passes through a cistern, and another tube iron fixed perpendicularly passes through another cistern; one cistern is placed at the back of the hearth, the other under the hearth, the front of the top cistern forming a fire plate. A pipe conveys the cold water from the upper cistern to the lower, and another pipe conveys the hot water from the lower cistern to the upper. The upper is supplied with water, and has an overflow pipe near the top. A tube passes through the cistern, which is held water-tight by a stuffing-box embracing a handle. By this handle the slot in the tube iron is placed to blow a vertical or horizontal blast as required. There is a blast pipe in an angular position, and an upright pipe in a vertical position, with a valve to let off the dirt or slag from the blast pipe. There is also a valve to the upright tube iron so as to shut off the blast and keep out the dirt when not in use. *Patent abandoned.*

984. E. S. THOWER. *Improvements in apparatus for treating flax, hemp, and other fibrous matters requiring like treatment.* Dated May 3, 1858.

When acting upon flax, &c., by grooved rollers, caused to move such matters alternately forward and backward (the forward motion being the greater), motion is given to the rollers by two straps, one crossed, the other not. These straps are caused to act alternatively on the driving drum of the rollers by a sliding bar or moveable instrument, which causes one strap to be moved on to the driving drum or pulley when the other is moved therefrom, and such bar or instrument is actuated by projections in the fly-wheel, so formed as to continue the driving strap for the forward motion a longer time in action than the driving strap for the retrograde motion. *Patent completed.*

985. J. TAYLOR. *Improvements in stoves and fire-places.* Dated May 3, 1858.

This consists in so arranging them that they may either be worked as ordinary stoves or fire-places, the smoke and products of combustion rising from the ignited fuel passing directly to the chimney; or that the direction of the draft may be so changed that the smoke, &c., are in part caused to pass down through the ignited fuel and between the bars, or through openings at the bottom of the grate, whilst a portion still rises from the top of the fuel. The part which passes downwards enters a chamber which becomes heated partly thereby, and partly by the heated fuel lying against the back of the grate, which forms one of the walls of the chamber. The smoke, &c., which rise from the fuel are also caused to pass into the heated chamber before escaping to the chimney. *Patent completed.*

986. J. G. APPOLD. *Improved apparatus for laying submarine telegraphic cables.* Dated May 4, 1858.

This consists in adapting to the shafts of the paying-out pulleys a drum, on the surface of which an uniform friction is maintained by binding bands or straps, connected with a weighted vibrating or moveable lever. This lever may be weighted to any desired extent, according to the friction required. The weights determine the friction on the rotating drums, and consequently the strain on the cables. *Patent completed.*

987. W. CLARK. *Improvements in separating and in otherwise treating matters in a state of fusion, and in apparatus for the same.* (A communication.) Dated May 3, 1858.

The apparatus above mentioned is intended to effect as much as possible the insulation of each molecule of the body in a state of liquefaction. It consists of two principal parts, I. A strong horizontal metal disc; 2. A perpendicular axis of iron. The two parts are firmly fixed to each other, so that rapid rotary motion may be communicated to the shaft without the disc flying off. If a flow of metal in fusion, or any other liquefied body, be directed on to the surface of this disc, the centrifugal force will spread the metal out towards, and project it from the circumference, and this metal will escape in large quantities if the movement is slow, but in drops if the movement is rapid, and in almost imperceptible particles if the speed be very high. *Patent completed.*

988. J. SMETHURST. *Certain improvements in boilers for generating steam.* Dated May 4, 1858.

This consists in constructing steam boilers of a series of spherical or other vessels in a line or above each other, and connected to a steam dome. The products of combustion are conveyed around these vessels. Another part of the invention is applicable to boilers in which flues are employed, and consists in applying within the flues spherical or other vessels connected to the inside of the boiler by pipes. *Patent abandoned.*

989. J. SWAIN and M. CERTAIN. *Improvements in metallic pistons.* Dated May 4, 1858.

This consists in the use of an internal elastic ring acting as an annular wedge, for the purpose of expanding the split packing rings of the piston, whether the connexions forming part of such elastic ring be made circular, oval, or in any other shape. *Patent completed.*

990. W. H. MORRISON. *Improvements in means or apparatus employed in the manufacture of bonnet and cap fronts, vouches, and such like articles of millinery.* Dated May 4, 1858.

These improvements relate to means of folding goffered or fluted lace or net, and to the application to the back or folded part thereof of bands or tapes. The band or tape gummed, is first placed over a groove in the table, and between a pair of sliding bars in position, for the edge of a blade or knife acting as a presser to come down thereon as operated by a treddle, and give a crease or fold thereto. Above these bars there is a pair of sliding plates which have a tendency to approach (by spring or other pressure) to within a short distance of each other, but are caused to separate as required by a treddle; and so soon as the tape is correctly laid over the groove, those parts which the treddle kept back are allowed to approach, and prevent the tape rising with the knife, and then analogous operations succeed. *Patent completed.*

991. H. L. MEALL. *Improvements in spring fastenings suitable to be used for dresses, brooches, and other purposes.* Dated May 4, 1858.

This consists in adding to an ordinary dress hook a spring tongue, to prevent the eye or loop through which the hook is passed when in use from accidentally coming off the hook. *Patent abandoned.*

992. W. E. NEWTON. *Improved apparatus for mixing and moulding materials for the manufacture of fuel, parts of which apparatus are applicable to moulding bricks and other analogous articles.* (A communication.) Dated May 4, 1858.

This relates to a former patent dated 20th March, 1858. The apparatus consists principally of, 1st, a mixing apparatus and, 2nd, a moulding and pressing apparatus. In the mixing apparatus the pulverised ingredients of the fuel are intimately combined by a rotating stirrer kept constantly in motion, while they are fed into the upper part from hoppers kept constantly supplied by a screw or endless series of buckets. Steam or hot air, or gas, is admitted to the lower part of the mixing chamber, and by the ingredients being kept in constant motion by the stirrer, the hot vapour will be brought into intimate contact with the carbonaceous matters, and will soften and cause them to agglomerate. By the continued rotation of the stirrer they are in a soft state forced out of an aperture at the bottom of the mixing chamber into a series of moulds, which are brought in succession under the aperture by a horizontal wheel or frame to which an intermittent rotary motion is communicated by gearing. In these moulds are fitted moveable pistons which are worked by a vibrating lever below, which has bowls or rollers to act against the under side of the pistons, and force them up to form, compress, and force out the blocks. This lever is actuated by a piston in a steam cylinder. *Patent completed.*

993. D. THOM and G. A. PHILLIPS. *Improvements in apparatus for bleaching and raising oil and fat.* Dated May 5, 1858.

This consists in bleaching oil and fat in high pressure vessels, and in conveying the vapours arising therefrom through a pipe into a closed vessel partly filled with water or other liquid, and from this vessel by another pipe into an open fire-place or flue. The patentees claim, 1, the use of high-pressure vessels in bleaching oil and fat. 2. The application of a closed vessel containing water or other fluid, through which the vapours rising from oil or fat during the process of bleaching pass before entering the fire-place, flue, or chimney, as described; and, lastly, the application of water or other liquid under pressure for raising fat and oil, as described. *Patent completed.*

994. R. SHARP. *Improvements in pianofortes.* Dated May 5, 1858.

This relates 1, to a peculiar application of tension braces to the ordinary braces or framework that sustain the tension of the strings, which render such braces less liable to warp or give way. The number of wood braces may therefore be reduced, or they may contain less wood than usual. 2. To a cheque action for upright pianos, and also to a particular application of the dampers. The details are not described apart from the inventor's drawings. *Patent abandoned.*

995. W. ROSS. *Improvements in taps or valves.* Dated May 5, 1858.

According to one form of these improvements, suitable for water-cranes or swan-neck taps, the crane or swan-neck is formed at its inner end with a hollow cylindrical valve piece, which works in a box or enlargement formed on the supply pipe. When the tap is open the fluid enters the crane or swan-neck through perforations round the cylindrical valve piece, the inner end of this piece being closed,

Digitized by Google

In closing the tap the cylindrical valve piece is moved longitudinally, and the perforations are covered by a ring of caoutchouc, or other flexible material, shaped spherically or conically, so as to tightly embrace the cylindrical valve-piece and at the same time serving as a stuffing for the aperture in which the crane or swan-neck works. The motion for the opening or closing the tap is obtained by a groove and pin, so arranged that on turning up the crane or swan-neck, an inclined part of the side of the groove causes the cylindrical valve-piece to move longitudinally. The improvements are susceptible of various modifications, and are applicable to various kinds of taps or valves. *Patent completed.*

906. C. D. ARCHIBALD. *A new and improved mode of treating air and gases, and applying the same for purposes of motive force.* (A communication.) Dated May 5, 1858.

The object here is to lessen the diameter of the pump of caloric engines by so treating the air or other gas that its volume will be greatly increased when in contact with heated surfaces above the same quantity when worked in its normal condition. The invention consists in saturating air or gas with water to its full capacity of retaining the fluid in a separate condition, previous to its contact with the heated surfaces. *Patent abandoned.*

907. J. H. JOHNSON. *Improvements in signal and indicating apparatus for railways.* (A communication.) Dated May 5, 1858.

This consists, 1, in a mode of notifying to the engineer or driver the approach of the train to various stations, crossings, switches, drawbridges, &c., and also of warning the attendants stationed at such points that the train is at hand. 2, To a mode of notifying to the passengers of a train the name of the different stations and localities to which they may be approaching. The first part consists in opening and closing the whistles of locomotives by projections placed between or outside the rails, and acting upon a pulley carried by the engine, and attached to a lever which transmits motion for sounding the whistle. A similar arrangement of projections is used for actuating a pulley and lever arm carried by each carriage for putting in motion when requisite an endless band of plates having the names of the several stations, &c., marked thereon, such band being situated within a case inside the carriage, and having an opening in front. *Patent abandoned.*

908. T. PRESTON. *Improvements in the manufacture of cut pile fabrics in warp machines.* Dated May 5, 1858.

The lower guide bar has, according to this invention, as many guides as there are needles, and the pile threads or yarns are carried by such bar, and are lapped alternately to the left and to the right over one needle, and the forming and cutting of the pile is arranged to work as described in the specification of a patent granted to C. Nichols, 12th Feb., 1849, but the cutting is caused to take place after the completion of each second course, and before the third course. The upper guide bar for carrying the yarns or threads for producing the back of the fabric is arranged to "shog," or move, so as to pass each of the threads or yarns under two, three, or more needles, and to lap on one needle, the lapping of the yarns or threads being caused to take place in the same direction as the lappings of the pile yarn or threads. The work is called "lap and press." When making fringes of printed or party-coloured, or other yarns or threads, the lower guide bar is caused to lap its yarns or threads as above explained. The forming and cutting of the pile is also as above described. Two upper guide bars are used; one is caused to pass under one needle and to lap on one needle, the lapping being in the same direction as the pile threads or yarns. The second upper guide bar is caused to traverse two needles in the opposite direction, that is, under and over one needle, the lapping being in the same direction as the thread or yarns of the lower bars. By the use of hard twisted looping threads, as described in the specification of a patent granted to C. Nickels, 9th Dec., 1848, the pile fringe made as above described will be caused to curl and become a chenille fringe. *Patent completed.*

909. W. S. HOLLANDS. *Improvements in extracting and purifying oils and fatty matters.* Dated May 5, 1858.

The matters containing the oils or fatty matters are placed on filters in a vessel surrounded with a jacket, to admit of the use of steam heat when desired. The filters consist of discs of wire cloth, or of perforated metal and felts, or filtering fabrics fixed at their edges on a projection formed around the interior of the vessel. The vessel is covered by a moveable cover, and provision is made for introducing jets of steam when desired. Below the filtering surfaces the vessel is closed, provision being made to allow of the space below the filters being exhausted to produce a partial vacuum, by which means the oils or fatty matters will be pressed by the atmosphere through the filtering surfaces. The oil and fatty matters will thus be quickly extracted, and also purified. *Patent completed.*

1000. J. LAWSON, and T. ROBINSON. *Improvements in machinery for hackling and dressing flax, and other fibrous substances.* Dated May 5, 1858.

This has for its object the so constructing hackles and fixing them to vertical double sheet hackling machines, that the points of the pins of the hackles shall penetrate the strick of flax at right angles or nearly so, and that they shall operate upon the flax nearer to the nip of the holder than has heretofore been the case in like machines when the hackles have been fixed to and travelled with the sheet. The novelty consists in making the stocks or surfaces (to one edge of which the pins or points are fixed), of much greater breadth than heretofore, and in fixing them to the endless sheets or bands at a greater distance from the pins or points, so that as the stocks with their pins or points come into action, they assume more quickly a vertical position and the points a horizontal position. The extra distance of the points of the pins from the points of fixing them to the sheet enables the points to penetrate nearer to the holder than heretofore. *Patent completed.*

1001. T. HOLSTEAD. *Improvements in machinery for the manufacture of certain articles of confectionery, which are also applicable to the manufacture of biscuits and the like, and to other articles from plastic substances.* Dated May 5, 1858.

This consists in several arrangements of apparatus for cutting, stamping, and perforating the paste or plastic substance of which such articles are formed. The details are very numerous and cannot well be described apart from the inventor's drawings. *Patent abandoned.*

1002. D. E. HUGHES. *Improvements in the means of and apparatus for transmitting signals and electric currents.* Dated May 5, 1858.

This relates, 1, to a former patent, dated April 27th, 1858, and consists in applying to such apparatus a treadle arrangement for winding up the clock work, whereby all risk of inconvenience from the clock work running down during the transmission of a message will be avoided. 2, To the working of electric telegraphs with feeble or attenuated currents, which result it is especially important to attain when submarine cables are used to convey the currents to distinct electric stations. To this end, in addition to the magnetic arrangement with which the receiving telegraph instrument will necessarily be provided, he proposes to work such instrument through the agency of a galvanometer, which, by the deflection of its needle or armature, will bring a local battery to act upon the receiving or recording instrument. 3, To certain means for enabling both the positive and negative currents (which are required to be transmitted through the cable in succession) to work recording or signalling instruments. These means cannot be described apart from the inventor's drawings. *Patent completed.*

1003. J. RICHARDS. *Improvements in rotary pumps.* Dated May 6, 1858.

This consists of a hollow cylinder to which is affixed a solid shaft, working through a hollow shaft carrying a cam, or two or more wheels affixed to a frame or the sides. On the surface of the cylinder are plates or flaps of equal width, but varying in breadth, according to the number, covering the entire periphery. These plates are all hinged on one side to the face of the cylinder and about their centre. On their sides slots are cut into the cylinder equal to the width of each flap, through which passes a quadrant, one side of which is secured to the under side of each flap or valve. On rotating the cylinder the enclosed wheels or cam remain stationary, and one portion of each quadrant in succession passes over the top surface of one and lower surface of the other wheel or cam, thus causing the flaps to rise and fall in succession in two portions of the case enclosing the whole. The case or cistern containing the water to be forced, has two inlet and two exit pipes. *Patent abandoned.*

1004. M. DAVIS. *Improvements in carriage wheels, and in means of retarding their motion.* Dated May 6, 1858.

The patentee claims putting the felloes together by edge plates of metal inserted in the ends of the felloes; the method of applying the spokes to the felloes by inserting metal plates as described; the formation of the caoutchouc band with a rounding bottom and lip, or with a rounding bottom or other figures as described; the iron tyre, the skid pan, and the making of wheels by the several methods as a whole, as described. The invention is not described apart from the inventor's drawings. *Patent completed.*

1005. J. S. WILLWAY. *An improved arrangement of apparatuses for ringing bells.* Dated May 6, 1858.

This invention was described and illustrated at p. 466 of the MECHANICS' MAGAZINE for Nov. 13, 1858, No. 1810. *Patent completed.*

1006. J. WHITLEY. *Improvements in the manufacture of iron, which improvements are also applicable when obtaining other metals from their ores.* Dated May 6, 1858.

In carrying out these improvements the air required to pass through the smelting or other furnaces employed in the manufacture of iron or other metals, in place of being forced through by a blast as heretofore, is drawn through by suitable exhausting apparatus. *Patent completed.*

1007. W. HEAP. *Improvements in pipe joints or couplings.* Dated May 6, 1858.

According to this invention when applied to soft metal a nut or loose collar having an external screw thread formed upon it is first passed on to each of the pipes to be joined together. The two contiguous ends of the pipes are then expanded, and an internal screw-threaded ring or ferrule is passed on to one of them. The two ends of the pipes are now brought in contact by screwing the ring or ferrule on to the opposite collar, so as to form a flush or pump joint, and they are then forcibly tightened up or drawn together by further screwing (by means of a spanner) the two loose collars into the ring or ferrule above referred to. No packing is required other than a little white paint. In the case of hard metal pipes the externally screwed collars are screwed on to the ends of the pipes to be joined, in place of being loose thereon. *Patent completed.*

1008. E. J. SCOTT. *Improvements in the manufacture of boots and shoes.* Dated May 6, 1858.

This invention consists in effecting the attachment of the sole by means of gutta-percha pegs, which are by preference shaped like screws to give them sufficient hold. *Patent completed.*

1009. H. ASHWORTH. *Certain improvements in machinery or apparatus for cutting hides or skins.* Dated May 6, 1858.

This invention was described and illustrated at page 578 of the MECHANICS' MAGAZINE, for Dec. 18, 1858, No. 1815. *Patent completed.*

1010. T. W. THACKER. *Improvements in the construction of the finger-keys of pianoforte, organ, and harmonium keys.* Dated May 6, 1858.

This consists in forming the finger keys of the natural notes with their ends tapered in a circular form. The black keys, or sharps and flats, are also made to taper towards the player, so as to give more room for the ends of the fingers to work on the natural keys between them. *Patent completed.*

1011. J. BRIDGMAN. *Improvements in cooling fluids and in the application of cold.* Dated May 6, 1858.

For producing a low temperature the inventor employs a mixture of ice with common or other salt, or with acids, or with salts and acids. He cools wort, or brine, or other liquids, by passing the cold liquids resulting from the freezing mixtures through tubes or passages immersed in, or in contact with the fluid to be cooled. The fluid to be cooled and the cooling liquid may be made to flow in opposite directions. He also conducts the cold liquid through pipes in the wort or in the brine. He also stores and preserves articles which require to be kept cool in chambers supplied with air artificially cooled by causing it to pass through the freezing mixture. *Patent abandoned.*

1012. J. CASEY, and J. HUGHES. *Improvements in looms for weaving velvet ribbons.* Dated May 6, 1858.

The object here is to weave two or more velvet ribbons simultaneously and in the same loom, with ordinary selvages. The inventor uses several shuttles, and limits their traverse movements to the traverse through their respective warps. These shuttles they mount in a race which is capable of sliding up and down in guides formed for it on the face of the batten or slay. This movement they require in order to prevent the weft threads from lapping round the pile wire and forming loops in the selvage. To facilitate the cutting out of the wires they provide a cutting board, which rises up to the fabric to sustain the down pressure of the cutting knife. The rise and fall of the shuttle race and of the cutting board may be effected by treadles, or by the Jacquard apparatus. *Patent abandoned.*

1013. W. E. NEWTON. *Improvements in the manufacture of saltpetre.* (A communication.) Dated May 6, 1858.

This invention is based upon the greater affinity possessed by nitric acid for potash than for soda, and the deliquescence of hydrate of soda, which allows of this hydrate being separated from nitrate of potash by simple washing. In carrying it out, potash is first rendered caustic by its own weight of newly slacked lime, and at least ten times its weight of water, keeping it boiling quickly in a closed vessel until a small quantity well precipitated or filtered is no longer acted upon by lime water. The potash lye thus obtained is allowed to settle, kept from the air, and decanted into a closed boiler containing a solution of nitric of soda well clarified by settle. The contents of this second vessel, after the chemical change has taken place, must be evaporated so as to obtain the greater portion of the saltpetre, which is crystallised out of the solution by cooling in a closed crystallising vessel, to which the boiling liquid is supplied by a cock or valve adapted to the second boiler. The mother liquor, which still contains saltpetre, is to be evaporated to a high degree of concentration, and again crystallised, and the solid matter thus obtained must be well drained (free from contact with the atmosphere) and may be a second time crystallised. The liquid portion remaining will be found to consist of a strong solution of caustic soda, containing scarcely any traces of saltpetre. This may, if required, be evaporated and run off to render it more portable. Instead of washing out the alkali it may be neutralised by the addition of a few drops of very dilute nitric or hydrochloric acid, leaving traces of nitrate of soda or chloride of sodium, the greater portion of which will run off in solution before the saltpetre is carried to the drying apparatus. As an accessory product, caustic soda will be found as a residuum after the process is complete. *Patent completed.*

REMARKS.—Railway Bars are firm and in fair demand. For other kinds of manufactured there is moderate enquiry, but prices are firm at quotations. Copper is firm and the demand good, particularly for manufactured. Tin is in request, and the tendency of price seems upward. Spelter is firm at quotation. In metals generally the business of the week has been limited.

THE
MECHANICS' MAGAZINE.
LONDON, FRIDAY, JANUARY 14, 1859.

THE STEAM NAVY OF FRANCE.*

On the 1st of January, 1850, the steam navy of France consisted of 20 frigates, and 86 corvettes and despatch vessels. Of the frigates two were of 650, two of 540, and 16 of 450-horse power each; of the smaller vessels one only was of more than 320-horse power, and most of them were of less than 200. There was not a single line-of-battle steamship then afloat in any harbour of France, but during the year the *Napoleon*, of 900-horse power, was launched, and the *Montebello*, a sailing ship, was converted into a steamer, with engines of 140-horse power only. Two smaller vessels—either corvettes or despatch vessels—were likewise launched in 1850. During the year 1851 no ships of the line and no frigates were added to the French navy; four small vessels formed the only increase of that period. In December, 1851, therefore, the number of vessels composing that navy was 114 in all. In 1852 three ships of the line were added—the *Austerlitz*, of 500-horse power, and the *Charlemagne* and *Jean Bart*, each of 450-horse power. Beside these, one frigate, of 260-horse power, and two smaller vessels, each of 400-horse power, were launched. In 1853 four more ships of the line floated in French ports, each of 650-horse power—the *Fleurus*, the *Prince Jerome*, the *Duquesne*, and the *Tourville*; and to these were added seven corvettes and despatch vessels, three of them of 400-horse power each. The next year, 1854, brought an increase of five line-of-battle ships; one of them, the *Bretagne*, a new ship of no less than 1,200 nominal horse power, and the other four each of 650-horse power, comprising the *Ulm*, the *Navarin*, the *Wagram*, and the *Souverain*. The number of smaller vessels remained stationary during that year. In 1855, the increase in the line-of-battle ships was six: viz., the *Eylau*, the *Redoutable*, the *Arcole*, and the *Algésiras*, all new ships, with engines of 900-horse power each, and the *Tilsitt* and *Breslau*, converted ships of 500-horse power each. This year, the most active year of the late Russian war, also brought into existence five floating batteries, 28 gunboats, and 14 screw transports. (We may, in passing, correct an error in the article from the *Conversations Lexicon* respecting the floating batteries. The writer says:—"The English batteries were complete failures, and could not even be propelled; the French, on the contrary, were excellent, and answered their purpose." The truth is, the English and French floating batteries were, to the number of four or five, built from precisely the same lines, and were, in all their main features, alike.) In 1856 seven additional line-of-battle ships were floated; of these the *Imperial* and the *Alexandre* were new, and of 900 and 800-horse power respectively; while the *Louis Quatorze*, the *Tage*, the *Duguay Trouin*, the *Donawerth*, and the *Duguesclin* were converted, and fitted with engines varying in horse power from 600 to 450. During the same year, 12 frigates, five of them of 800-horse power, were added, and the number of corvettes and despatch vessels was reduced by 10. The number of floating batteries and gunboats remained the same as in 1855, and has, indeed, continued the same until now. The screw transports were not added to this year. The *Ville de Paris* and the *Turenne*, each of 600-horse power, and the *St. Louis*, of 450, were the only line-of-battle ships added in 1857. The frigates were increased by four, the corvettes by one, and the transports by six, in that year. In 1858 the *Ville de Nantes*, of 900-horse power, and the *Fontenoy*, of 650, both new ships of the line, with four corvettes and three transports, were launched.

If the foregoing numbers be brought together, they give these results, viz.: that during the last seven years—that is, since the flash of the *coup d'état* prepared the world for the Empire's thunder—the number of French steamships of war has been more than doubled (being 114 in January, 1852, and 230 in January, 1859), and the number of steam line-of-battle ships raised from two to 32. To complete the statement of the case it is necessary to add, that at the present moment eight ships of the line and 25 frigates and smaller vessels are building in the French dockyards. The line-of-battle ships are the *Intrepide*, the *Ville de Bordeaux*, the *Ville de Lyon*, the *Gloire*, the *Invincible*, and the *Normandie*, 900-horse power each; and the *Massena* and *Castiglione*, 800 each. The *Gloire*, the *Invincible*, and the *Normandie* are building on the lines of the Napoleon razéed, and are to be sheathed with thick iron plates. The order for the conversion of two other ships of the line, the *Friedland* and the *Bayard*, has been issued, but the works have not yet been commenced.

From the foregoing facts, it appears that since the supreme power of the French nation has been in the hands of Louis Napoleon the French navy has received an average increase of from four to five steamships of the line annually; and the number of similar ships now on the stocks gives an unmistakeable proof of his intention to exceed that average this year. In an article in the *Times* of Saturday last, the Editor has shown with perfect clearness that, notwithstanding these great strides, we have the strongest steam navy in the world; and we endeavoured in the Society of Arts' paper to prove that with an efficient Channel fleet we should stand in no peril of invasion. But the steady and enormous increase of the French steam navy in large ships, appears to point to something very different from a sudden and unsupported descent upon our coast. Two-deck and three-deck steamships are by no means the most fitting vessels for effecting such an operation. They are intended, as their name implies, for the line of battle, and their production in large numbers by the French Emperor is equivalent to a declaration that if we have to meet his forces at all, it will not be on our coast or in our harbours alone. He is manifestly preparing to meet us, if need be, or if occasion serve, on the open sea, and to contend there for a mastery of infinitely greater value to him than any mere momentary advantage.

These are not alarmist notions, but plain matters of fact; and they raise the question,—Is England, with her home interests, her Mediterranean ports and islands, and her wide-spread colonies, to see herself surpassed, or even equalled, in her lines of battle, by a neighbouring Power which has but little save its own seaboard to defend?

E. J. R.

* The facts contained in the above article are so important that we deemed it our duty to send them for publication to the *Times* in a letter which appeared on Wednesday last.

SUBMARINE WARFARE.

Scarcely have Admiral Sartorious and Mr. Nasmyth allowed their "rams" to be driven to the fold, before an American gentleman has come hither with a still more remarkable fighting animal—an amphibious creature of so terrible a nature that it is to "put war steamers out of the question, and render of no avail the tremendous forts of Cronstadt or Gherbourg." This is not an ideal, but a veritable existent being—that is, if there be any truth in American oaths, for we have been favoured with the perusal of a roll of affidavits declaratory of its exploits. Indeed, we have seen drawings of it, and have, to some extent, examined its various powers and functions—with one exception: it has a secret power of loading cannon under water, the nature of which its proprietor will not divulge. There are some ingenious points about this—what shall we name it? say, dexterous hippopotamus; but, in the main, we do not discover any very remarkable novelties in its constitution. The account of it, which we are permitted to publish, however, is sufficiently startling. It is a submarine boat resembling a porpoise, but capable of containing 15 men if necessary. The inventor has, with others, sunk in Lake Michigan, and remained under water for four hours, without any communication from the surface, and has propelled the boat in and near the bottom of the lake for several miles, at three miles an hour. He has, while under water, by machinery working through the boat's side, sawed off timbers 14 inches square. He can sink his boat from the surface almost instantly, either to a few inches, or to 100 or more feet, and again rise quickly or slowly to the surface; go forward, back, or sideways, or come up bows first or otherwise, as may be required. He can carry powder torpedoes under water out to sea, in any weather, to an enemy's ship, fix or anchor the torpedoes under her bottom, set in motion clock-work to fire the torpedoes, and retire out of danger. He can enter an enemy's harbour under water and make surveys, only showing above the surface a sight tube half an inch in diameter, retire and make his report. He can go out to sea, meet a hostile fleet, go under their bottoms, fix torpedoes, or bore holes, and come away unseen. He can carry a gun so rigged that he can load in 100 feet of water, rise near to the surface, sight the horizon for an enemy's ship, proceed within a stone's throw of her, rise quickly, so as only to show the muzzle of the gun through the outside port-hole valve, aim at the ship, fire, then instantly sink to reload, and rise at another point to fire again. If required, he can remain under water with several men for several days, without landing, or showing his boat above water. For pearl fishing, he can work all day on a pearl bed, raking up and taking in pearls, and moving about and finding them where a diver would not. If required, on visiting wrecks, he can saw, bore, or make fast chains or ropes to any point of the wreck, go out of the boat through the side-hatches, enter the vessel, and return inside again without inconvenience. In our judgment, the submarine dress or case which the inventor has devised for these latter purposes, is a most complete and useful contrivance. We shall publish an illustrated description of it hereafter.

When the invention was first brought under the notice of the Secretary of the United States' Navy, he wrote to the inventor to say that the American ships were required in the water and never wanted to go under them. A proffer to the Emperor of the French received no answer. But when the invention was brought a few days since under the notice of the English Board of Admiralty it received full and prompt attention, and Sir Baldwin Walker has already had interviews with the gentleman to whose care the disposal of the patent is intrusted. But we doubt whether the system—so often commenced, but so seldom leading to any successful issue—of endeavouring to sell a secret, will in this case meet with any success. The means of doing all that this American gentle-

Digitized by Google

man proposes are already within our power. The reason they are not used is, that they are attended with great cost, uncertainty, and danger; and it is difficult to believe that any secret can at a stroke remove these. The proposals themselves are by no means new. FULTON, in his day, proposed similar schemes. He had his "mute," which floated when he pleased, and sank below the surface when he pleased; and he had his submarine boats, which could go entirely down, and propel themselves horizontally and vertically by screws. But he was beaten in the end. On the other hand, submarine warfare will doubtless become a simple thing enough in the course of time, and we would offer no obstructions to its advent. Only, if we undertake to build a boat at our own expense, we should first assure ourselves that the invention is promising; and if our visitor undertakes to build one, we must stipulate for a really useful result before we agree to pay for it.

THE EXHIBITION OF 1861.

IT would be folly to suppose that all the great benefits which the arts and manufactures derived from the Great Exhibition of 1851 were contingent upon the novelty of the undertaking. The mere bringing together of the products of industry exerts a wholesome stimulus upon industry itself. If the collection be small, the stimulus is slight; if the collection be universal, the stimulus is equally so. The periodical exhibitions of agricultural, botanical, and other societies, never fail to produce good; and it is scarcely possible to believe that similar exhibitions of the works of art and industry, in the aggregate, would be less certainly productive of advantage. For these reasons we learn with satisfaction that the Council of the Society of Arts, bearing in mind the part which the Society took in originating the Great Exhibition of 1851, have considered it to be their duty carefully to examine the various suggestions for holding an exhibition in 1861, which have been submitted to them, and have resolved:—1, That the institution of decennial exhibitions in London, for the purpose of showing the progress made in industry and art during each period of ten years, would tend greatly to the "encouragement of arts, manufactures, and commerce." 2, That the first of these exhibitions ought not to be a repetition of the Exhibition of 1851, which must be considered an exceptional event, but should be an exhibition of works selected for excellence, illustrating especially the progress of industry and art, and arranged according to classes, and not countries; and that it should comprehend music and also painting, which was excluded in 1851. 3, That foreigners should be invited to exhibit on the same conditions as British exhibitors. 4, That the Council will proceed to consider how the foregoing resolutions can be best carried into effect.

If any one should be so astute as to suppose that ten years is a period in which no sensible advances are made in the arts and manufactures, he is egregiously mistaken. "Looking back for that period in England," says the *Globe*—and we see not how to put the case more effectively—"we find that several new arts and industries have arisen, and old ones have been extended. Scarcely more than ten years have passed since the submarine telegraphs were unknown; the screw propeller applied to our steam-vessels; the glass duty removed; the great improvements and advancement in the trade and products of the Staffordshire potteries effected; the manufacture of bricks left free to take such form as may be required; the excise duty on soap got rid of; photography and chromatic printing introduced and perfected as arts; gutta percha and many vegetable oils from our Colonies, such as the Bassia Latifolia and the Cahoun Palm, introduced as new raw materials in commerce; whilst the declared value of our exported manufactures has risen from 65,756,000*l.* in 1851, to 122,155,000*l.* in 1857. Add to the above the fact, that within ten years the resources of our Colonies have been largely developed, and the commercial world has acquired three additional emporia—two on the shores of the Pacific, and one on the Great American Lakes, viz., San Francisco, Melbourne, and Chicago, none of which are even named in the edition of Mr. M'Culloch's 'Dictionary of Geography,' published in 1849; also that China and Japan have now been opened to trade with England; and we cannot but come to the conclusion that ten years is a period fully sufficient to justify the Society of Arts in proposing to hold an Exhibition in 1861."

THE LONDON MECHANICS' INSTITUTE.

AFTER its thirty-six years of existence, the London Mechanics' Institution is not only heavily in debt, but the burden of its debt is about to be laid upon the illustrious BROUGHAM, who was associated with Mr ROBERTSON and Dr. BIRKBECK, in its formation, and who became one of its trustees. To prevent this result—which would, indeed, be a monstrous blur upon the intellectual splendour of the age—a statement has been put forward by the friends of the Institution to the following effect:—This Institution, the first of its kind, has been the parent of more than 600 similar establishments now in existence, and its founder has therefore a peculiar claim on the liberality of all friends of education. The premises required for the purposes of the Institute were demised to Lord BROUGHAM and others for a term of 146 years, at an annual rent of £229. For 30 years the voluntary contributions of the public and annual payments by the members enabled the Institute to meet all its expenses; but for the last three years and upwards, the receipts have been insufficient. In the event of Lord BROUGHAM'S co-lessee, who is of advanced age and in bad health, dying before him, the *whole* future responsibility would fall upon Lord BROUGHAM alone, and he, under the terms of the lease, can only be entirely relieved by purchasing the lease at a sum of £3,500. But it has been ascertained that if £2,000 could be raised at *once* arrangements might be made with the lessor not only to free Lord BROUGHAM from all future liability, but to enable the London Mechanics' Institute to continue its useful labours. It has occurred to Lord MURRAY and other friends of Lord BROUGHAM, considering the great public services he has performed, (more especially in the cause of education), and the heavy expenses he has already incurred, that he is fully entitled to be protected from further pecuniary loss. Contributions may be paid in to Messrs. RANSOM, BOUVERIE, and Co., 1 Pall Mall East, "To the account of the London Mechanics' Institute, *on behalf of Lord Brougham*." Surely we need add no word to an appeal like this! Surely every reader of this Magazine will cheerfully contribute his cheque or his note, his gold guinea or his silver mite, to help to save our common reputation!

EXHIBITION OF INVENTIONS.—The Society of Arts' eleventh annual Exhibition of inventions will open on the 25th day of April, 1859. The days fixed for receiving articles intended for Exhibition are, Thursday, the 7th, Friday, the 8th, and Saturday, the 9th of April. No charge is made for space, and the Exhibition is free.

LAYING-OFF;
OR,
THE GEOMETRY OF SHIP-BUILDING.

No. I.

MOST persons are aware that the art of ship building has three great divisions—construction, laying-off, and actual building. The first consists in designing and making a scale-drawing of a floating body, which shall answer all the required conditions as to carrying power, stiffness, speed, and whatever else may be necessary. This is, to a large extent, a mathematical operation. The second division, "laying-off," consists in forming upon a prepared floor, another drawing of this floating body, having her intended dimensions in full, to which drawing moulds of thin wood are cut, determining the forms and sizes of the several parts, that by them the workmen may perform the third and last process—*i.e.*, cut out the solid timber, so as to ensure that when the several parts are brought together their aggregate shall have the contour and magnitude intended by the constructor. The first of these divisions will be thoroughly considered in the series of articles concurrent with this. The second will be the subject of this series. The present text-book on the subject is that written by Mr. Fincham, late master-shipwright of Portsmouth Dockyard, and is a complete manual guide to all the details. Our object is quite remote from this—it is to show the dependence of all its problems upon the common principles of projection-drawing, and to give such an outline of these as shall render us intelligible in obtaining by their aid the required solutions.*

Presuming that the reader has a thorough knowledge of the constitution of a ship, he can find no difficulty, if he aid his conceptions with a few pieces of card-board, in comprehending all that we shall submit to him, and in reducing to practice the knowledge so obtained.

It will be our endeavour, by the avoidance of technicalities, and by careful definition, to render ourselves intelligible, not only to the ship-builder, but to every geometrician, to whose attention we commend the subject, as one of great interest, both from its importance in its relation to ship-building, and from the skilful adaptation of geometrical principles shown in many of its solutions.

Our first object, then, must be to describe the nature of a ship-drawing.

ON PROJECTIONS.

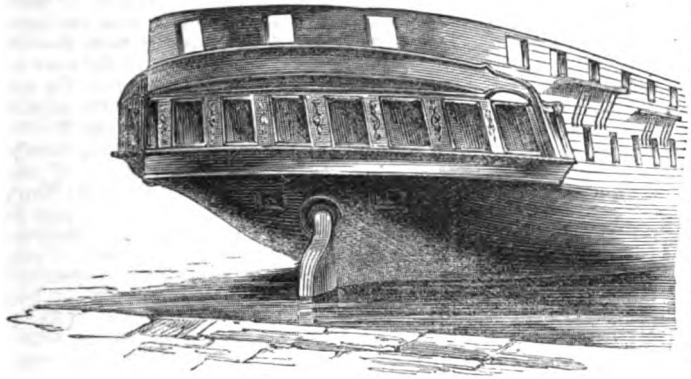
In landscape and other *perspective* drawings all the objects represented are placed in that relation to each other which they appear to bear when viewed from some one point; and where exact dimensions are not required, nothing further is necessary; but if we wish to apply a scale to the drawing, to discover the sizes and distances of the objects represented, we shall find that the perspective drawing will not serve our purpose. We must have a drawing which will give us the objects as they are with regard to position and magnitude, not as they appear to the eye of a spectator. We must get rid of the notion of perspective, and introduce that of *projection*, or orthographic projection, as it is frequently called.

Fig. 1 is a perspective drawing of the stern of a sailing frigate, representing truly enough the appearance of the ship viewed from a point on the quarter, but evidently having no value as a means of determining the sizes and relative positions of the parts. What we need to complete our knowledge of any solid, or group of solids, in these respects, is to have the means of observing them, not from one point alone, but from successive points immediately in front of each part, and from others immediately over those parts, having at the same time the power of seeing through the solids. A projection-drawing gives us these means, and this knowledge.

* More complete knowledge of this subject may be obtained from Dr. Woolley's admirable "Descriptive Geometry," Parker, West Strand—or from Binns' "Orthographic Projection," Spon, Bucklersbury.

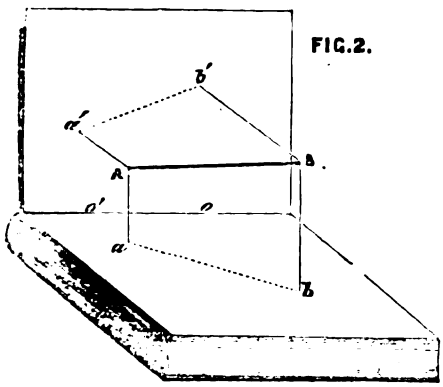
Digitized by Google

Fig. 1.



Projection means literally throwing forward, and the word is used here in some such sense. Let us see how to represent a line by its projections.

FIG. 2.



Take a book, fig. 2, and open its cover, as shown in the sketch, so that the *plane* of the cover may be at right angles, or square to the plane of the first leaf. These two flat surfaces, or planes, we shall call the *planes of projection*, because upon them we are going to *project* the line *A B*, held in front of one, and above the other as shown. Now suppose perpendiculars to be let fall from the point *A* upon the cover, and also upon the first leaf—in other words, let the line *A a'* be drawn from *A* square to the cover, and meeting it in the point *a'*; and *A a*, square to the first leaf, and meeting it in *a*. In a similar manner let perpendiculars *B b'*, and *b b* be drawn to the cover and leaf respectively from the other end of the line *A B*. Then *a* and *a'* are said to be the *projections* of the point *A*; *b* and *b'* of the point *B*; and it is evident that if these points were marked on the planes, we could always find the points in space which *A* and *B* had occupied by drawing perpendiculars to the planes from the projections, and finding where they intersect. We know in fact that—calling the line *o o'* in which the two planes intersect, *the axis*—the height of *a'* above the axis is equal to the height of *A* above the plane of the leaf, and that the distance of *a* from the *axis* is equal to the distance of *A* from the plane of the cover. We have similar knowledge with regard to the point *B*; and it is manifest that if we draw a straight line from *a'* to *b'*, and another from *a* to *b*, they will show us the position and length of the line *A B*, of which they are the projections. Both (*a*, *b*) and (*a'*, *b'*) are in this case shorter than the line *A B*, because this line is not parallel to either of the planes of projection. Had it been parallel to either, the length of the projection on that plane would have been the same as the length of the line; but it will be seen presently that the exact length can in any case be easily found from the projections. By these means, then, we have recorded upon two planes, at right angles to each other, the position of a line with relation to them.

If we suppose further that the two planes which we have chosen to receive our projections are not only perpendicular to each other, but are also the one *horizontal*, and the other *vertical*, we by this means, record also the inclinations of the lines projected to the vertical. As it is important to do this, it may be understood for the future that one of our planes of projection is horizontal, and the other vertical, and we shall designate them the *horizontal plane* and the *vertical plane* respectively.

There will not be much greater difficulty in representing a curved line by its projections than we have found in representing a straight line.

FIG. 3.

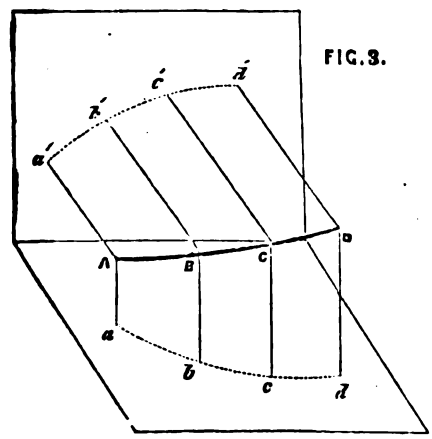


FIG. 4.

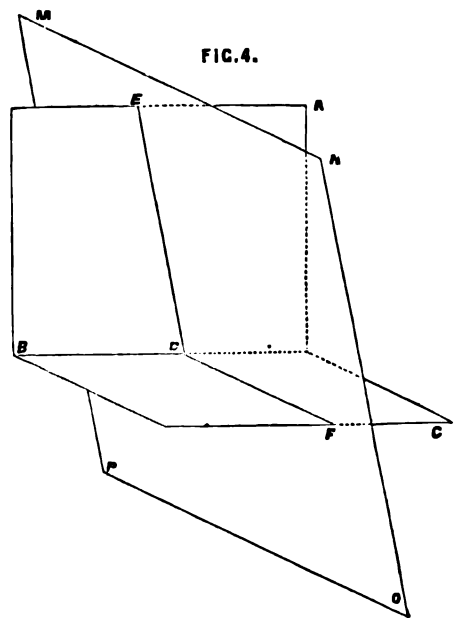

If the line is regular in form it will only be necessary to project a few of its points, *A*, *B*, *C*, *D*, on the planes, fig. 3; *a'*, *b'*, *c'*, *d'*, and *a*, *b*, *c*, *d* may then be joined by regular curves, and every point in them may be considered to be the projection of the corresponding point in the line. If, conversely, it is required to discover the curve, *A D*, from the projected curves (*a*, *d*), (*a'*, *d'*,) we have only to draw perpendiculars to the planes of projection from these and other points intermediate, and the points in which these perpendiculars intersect will be in the required curve.

These projections will not be similar in form to the line projected, unless the line *lie in a plane parallel* to one of the planes of projection. In that case its projection on the plane to which it is parallel will be precisely similar to itself, while that on the other plane will be a straight line.

Any point or line, and therefore any plane or solid figure bounded by lines or surfaces, may thus be represented by its projections.

If we wish to define the position and direction of a *plane* having no precise boundaries, it is sufficient to show the lines in which, when it is extended, it will cut the planes of projection. Let *M*, *N*, *O*, *P*, Fig. 4, be the plane to be represented. This representation might be made by obtaining the projections of any three points in it, not in the same straight line, but instead of doing this, the lines *E D*, and *D F*, are marked, and are called the traces of the plane. The position and direction of the plane are thus completely determined.

THE NAVIES OF ENGLAND AND FRANCE.

(From the *Times* of Saturday, Jan. 8, 1859.)

We promised our readers a little further notice of the comparisons instituted by certain German critics between the navies of England and France. This undertaking we proceed to fulfil. In so doing we shall direct our own remarks to a single important point, not simply for the sake of unity or perspicuity, but because much of the rest may really be dismissed without regard. We are not in the least disposed to fight over again the battles of the last naval war, nor shall we join Sir Charles Napier, whose letter will be found in another column, in analysing the elements of British victory. Still less shall we discuss at present the disparaging statements respecting our officers and men, to which the natural sense and information of the public will apply the best corrective. The comparative strength, however, of the English and French navies in actual material is a truly interesting subject of inquiry—all the more so, indeed, from being fairly debateable, and it happens that we have very lately been favoured with some instructive observations on the matter by very competent hands. Sir Howard Douglas, in his recent treatise on *Naval Warfare with Steam*, and Mr. Reed, late of the Portsmouth Dockyard, in a paper upon Naval Architecture, read before the Society of Arts, have each entered with considerable minuteness into the question before us, and in addition to these authorities, we learn from an article transferred to our own columns this morning what view is taken of the case in the United States. With these aids we think we can make the facts tolerably clear.

The German critic allowed 546 men-of-war of all rates to England, and 450 to France, gun-boats alone being excluded from the calculation. Taking ships of the line only, France was credited with 63 and England with 78, the proportion of steam to sail in either force being reckoned equal. After a decided superiority, however, had been thus assigned to England, it was presently demolished by the assertion that the advantage was merely nominal, since the French ships were mostly new and of prime capacity, while many of the English were old and of no real account. As a final conclusion, the Navies of the two nations, in respect of material, were pronounced to be pretty nearly on an equality.

Very different is the contrast exhibited by Mr. Reed, who broadly says, "Where we have 60 steam line-of-battle ships they (the French) have 30; where we have 330 steamships, they have 220; and where we have 600 ships in all, they have 400." In like manner the American journalist gives us a majority in screw ships of the line of 52 to 33; and, though he represents us in a minority as regards first-class steam frigates, this is because he omits paddlewheel vessels, and enumerates none but screws. Mr. Reed gives us exactly the number of these vessels assigned by the New York paper to the French—viz., 28, instead of 19,—remarking that they are "most of them powerfully, and some of them very formidably, armed, the engines of 16 of the 28 being at least of 600 nominal horse power." Sir Howard Douglas, in his recapitulation of the vessels of the British Steam Navy, also supplies a correction of the American estimate. He reports that we have 32 ships of 90 guns and upwards, 32 from 50 to 90, 27 from 20 to 50, and 127 with 20 guns and under, independently of our gunboat flotilla. Ordinary readers will probably be somewhat puzzled to understand how there can be such variations in a simple affair of reckoning, and will think that our ships ought to admit of counting and classifying without much chance of error. But there are two main sources of discrepancy in this matter. One is, that ships on the stocks, or under alteration, may or may not be counted, according to the views of the enumerator; and the other is, that a particular class of vessels—such, for instance, as our 60-gun block-ships—may sometimes be computed as line-of-battle ships, and sometimes be assigned to another division of the Navy. As regards the chief point taken—viz., the respective forces of the two Navies in good, sound, effective line-of-battle ships, propelled by screws,—we believe we can put the case plainly before the public.

Digitized by Google

The French Navy contains 33 screw sail of the line afloat. Of these 21 have been launched since 1852, and the average age of the whole 33 is 7 1-3 years. On the stocks in the different dockyards there are six more vessels of this class, giving a total of 39. The British Navy comprises 37 screw sail of the line afloat, if we include six fitting for the screw. Of these 20 have been launched since 1852, and the average age of the whole 37 is 9¼ years. On the stocks we have 12 building and four ordered to be altered, giving a total of 53. That, according to the best of our information, is the true state of the case.

It is not to be denied that these figures admit of a deduction furnishing something very like a warrant for Lord Hardwicke's estimate of the two Navies, which occasioned so much sensation two or three months ago. Striking out vessels fitting or building, we find ourselves with 31 line-of-battle ships of the first quality, whereas France has 33, so that Lord Hardwicke was thus far justified in speaking of a positive inferiority on our part. But this, in reality, is giving us rather hard measure. It takes no note of ships coming on, though here we have decidedly the advantage, and the balance, in fact, might have been turned the other way before the calculation was well completed. It leaves out of the question our clear preponderance of strength in other classes of vessels, and in the general aggregate, taking no heed of blockships, heavy frigates, corvettes, or, above all, of gunboats. These considerations might have given a different turn to the conclusion, though we must needs admit, after all, that the comparison of force is too close to be agreeable to the British people. The truth of the whole matter seems to be this:—The definite recognition of steam as the essential power of a War Navy rendered old Navies, as it were, obsolete at a single blow, compelled all maritime Powers to begin shipbuilding afresh, and thus deprived England of the start which years of enterprise and outlay had given her. In this conjuncture of affairs, France, partly by patience, partly by judgment, and partly by well-directed vigour, did for a time gain a stride or two upon England. Wisely sparing herself all useless efforts, she took the benefit of our experiments, and then, by concentrating her expenditure upon one class of vessels and turning these out upon the very best model, she succeeded in making a better bargain than we did out of the new order of things. But since that time we have been steadily coming up, and it must be the fault of our rulers if we do not soon regain our position hand over hand.

Before we conclude, however, we wish, not to discuss, for there space would now fail us, but simply to open one or two questions, by the solution of which the whole case may be most materially modified. Are screw line-of-battle ships such all-important elements of a naval force that a comparison of numbers in this class of vessels alone becomes equivalent to a comparison of two marines? It is quite certain that frigates, corvettes, and especially gunboats, may not play parts of very great consequence in any future war! We may go a little further in our inquiries. Has it been really placed beyond all doubt that steam will stand for everything, and sailing for nothing, in maritime campaigns? Mr. Reed does, indeed, suggest that some of our 200 sailing vessels should be sold for merchantmen, as never likely to be useful; and Sir Charles Napier, it will be seen, also rejects these vessels from his estimate of our naval strength. Such views of the subject are doubtless correct, as far as the construction of any new sailing vessels is concerned; but Sir Howard Douglas has sagaciously pointed out that steam, in any long cruise or tedious operations, can only be looked upon as an auxiliary power, to be employed at the most critical moments. Men-of-war have but moderate capacities for stowage of fuel. Our best vessels of this class carry but six or eight days' consumption, and the Napoleon—the French type ship—could only go two days longer. In anything like a sea campaign steamers would have to depend, like land forces, upon some base of operations, and receive regular supplies of coals. Even under the most favourable circumstances they would have to economise their fuel whenever it was possible, and trust to their sails. This would not, it is true, bring mere sailing ships up to their level, but it shows that seamanship is not so obsolete a qualification as some have imagined, and that British sailors may still find a sphere for excellence peculiarly their own. Altogether, we think that steam has done less to injure the relative power of Britain than our foreign critics are pleased to assume. At this moment we have certainly the strongest steam navy in the world taken in the aggregate, and probably in any class of vessels taken singly. This force we shall continue to increase and maintain in the points where increase is desirable, while it still remains a matter of uncertainty whether in what we possess over and above steam power we may not find many of our old advantages yet remaining.

SCIENTIFIC PROGRESS IN AUSTRALIA.

As many necessarily vague ideas prevail with regard to the details of the progress of that portion of the Anglo-Saxon race which has "projected" itself on to the Australian continent, it may be interesting to afford a little information on such subjects as come within the scope of this journal. We are induced to do this because it is difficult to take up an Australian paper without meeting with complaints of the indifference and misapprehension which prevails in England on topics of absorbing interest to the colonists. For example. The north part of the province of South Australia has recently been reported to be teeming with yet undeveloped mineral wealth. The colonial journalist in "South" Australia refers to the discoveries "in the north;" some of his English contemporaries reproduce the observations without much care; and the home reader, if he troubles himself about the matter at all, and has any smattering of antipodean geography, is led to the conclusion that copper had been found somewhere in the neighbourhood of the Gulf of Carpentaria, instead of in the vicinity of Lake Torrens.

That the Australias are approximating more and more to the habits and system of the old country is seen in the rapid progress which the electric telegraph has made of late years in the three leading British settlements—Victoria, New South Wales, South Australia—and in Tasmania. A paper issued by "one" of the local parliaments—there appear to be too many legislative cooks on the continent—shows that the development of what the Indian mutineers call, we believe, the "lightning mail," has been very great during the last two years. A great intercolonial telegraph has been in hand for some time between the capitals of Adelaide, Melbourne, and Sydney. The line has been in operation since the summer between Adelaide and Melbourne, and the last advices state that it has now been finished between Melbourne and Sydney. There are now, therefore, 1,650 miles of telegraphic wire on the Australian continent and its island-satellite, Tasmania. Of this total of 1,650 miles, not less than 1,200 miles of wire have been put up within the last two years, showing an accelerated rate of progress due to the prosecution of th intercoloniale line. This last was, of course, a serious undertaking, and could not have been carried out without the co-operation of the various colonial governments. The wires are for the most part carried along standing trees, and fears were in the first instance entertained that the various disasters of the bush, and the wanton malice of the Aborigines, would prove fatal to the undertaking. At present the *contretemps* experienced have not been of a very serious character; and some provision has been made against the effects of bush fires by clearing the undergrowth away from the trees which have been pressed into the service as supports for the wires. It remains to be proved whether this will be a sufficient security against the wide-spread conflagrations, which are greatly favoured by the dryness of the climate; but with the advance of civilisation and cultivation these will probably become less frequent. Under any circumstances, however, for some time to come it will be necessary to devote much attention to the removal of the undergrowth, which will soon spring up again. Victoria, forced by its auriferous wealth into an importance unparalleled for the rapidity of its growth in colonial annals, has the greatest length of telegraphic communication, 735 miles; New South Wales comes next with 393 miles; South Australia has 338 miles; and Tasmania 160 miles. With regard to the future, a line is in progress from Castlemaine to Ballaarat, and another from Queenscliffe to Cape Otway, to meet the submarine cable, which is about to be submerged from Tasmania, in Bass' Strait. In South Australia a line is being pushed on to Kapunda, to the north of Adelaide. In New South Wales additional lines to Bathurst and the Hunter River have been sanctioned, and are expected to be carried out in 1859. In Tasmania a line from George Town to Cape Grim, between which point and Cape Otway the submarine cable is to be submerged, is also not yet constructed. The cost of the lines at present in operation has ranged at from £70 to £75 per mile. The rate of charges for messages is necessarily high, but between Adelaide and Melbourne, the pressure of telegrams has been found to be inconveniently great, so much so, indeed, that some despatches have not been delivered for 24 hours after their reception. The business between Melbourne and Sydney will, of course, be more extensive in consequence of the larger interests involved in New South Wales; and as there will be a constant succession of governmental and fourth estate despatches, the wires will, no doubt, be fully employed.

A recent American writer expresses an opinion that Australia must always suffer greatly from the inferiority of her rivers. This is, no doubt, true from an American point of view, and comes naturally enough from a traveller fresh from the Mississipi or the Ohio; but it is all the more important that the colonists should make the most of what inland streams they have. The most important and extensive of these are the Murrumbidgee and the Murray, and persevering attempts are being made to extend steam and other navigation on these rivers. Perhaps the Murray is almost the only reliable river in or near the settled districts; the other streams discovered being mere channels filled by occasional rains, which, in some cases, rush down comparatively naked hills, according to Sturt, without being absorbed more or less by vegetation as in Europe, and cause an accumulation of waters extraordinarily sudden, and soon carried off by evaporation. The waters of the Murray maintain throughout its course of many hundred miles a tolerable equilibrium; and the Murrumbidgee, which is connected with it, is also a fine stream, although variable. Captain Cadell, who has devoted considerable attention to this important Australian question, has succeeded in steaming along the Murray from the Goolwa, in South Australia and also in subsequently ascending the Murrumbidgee as far as Gundagai. As the channel is not well known at present, the progress of the steamer was slower than the speed which others will, no doubt, subsequently attain. The entire distance traversed was more than 2,000 miles, and the journey occupied 34 days. It should be stated however, that the steamer had in tow three barges. As a specimen of the barbarous character of Australian nomenclature, the log of the steamer is rather amusing:—Left Alexandrina on the 12th August with barges *Wakool*, *Eureka*, and *Milta-Milta* in tow; arrived at Moorundee 13th, Darling junction 21st, Murrumbidgee junction 27th (cast off the *Eureka*), Balranald 28th, Niela and Pika 30th (cast off the *Milta-Milta*). Lachlan station 1st September, Lang station 4th (cast off the *Wakool*), Yanko 10th, Wagga-Wagga 13th, and Gundagai 16th. Steam navigation is not a novelty this year on the Murray, as Mr. Randall, an enterprising agriculturist in South Australia, placed a small steamer on the river a season or two since; but the trip to which reference has been made, was the first of the kind witnessed on the waters of the Murrumbidgee, and it is almost impossible to overestimate the commercial importance of the expedition to the colonists. It is suggested that a similar attempt should be made on the Darling, but this stream is so uncertain that the success of such an enterprise would be doubtful; at any rate, the prospects of any permanent navigation on the river seem dubious. As an illustration of the uncertainty of Australian rivers—if such an expression is allowable—it may be worth while to compare the statements, no doubt *bonâ fide* in each case, but made under widely different circumstances, by Sir T. L. Mitchell, for some time Surveyor-General of New South Wales, and Mr. A. C. Gregory, the chief of the expedition despatched as a forlorn hope in search of the gallant Leichardt. Sir Thomas Mitchell, who visited the district through which flows the river which he named the Victoria in 1845, wrote as follows on his discoveries:—"The soil consists of rich clay, and the hollows give birth to watercourses, in most of which water was abundant. . . . The plains were verdant; indeed the luxuriant pasturage surpassed in quality as it did in extent anything of the kind I had ever seen. . . . New birds and new plants marked this out as an essentially different region from any I had previously explored. That the river is the most important of Australia, increasing as it does by successive tributaries, and not a mere product of distant ranges, admits of no dispute; and the downs and plains of Central Australia, through which it flows, seem sufficient to supply the whole world with animal food." Thus Sir Thomas Mitchell; but Mr. Gregory, who has just returned

Digitized by Google

from his expedition, visited the same district, and writes: "The bed of the Victoria was scarcely ten yards wide (at one point), and perfectly dry, so that it was only after a prolonged search along its course that a small puddled water was found in a hollow. . . During the first two days' journey down the river only a few small pools of water were seen, and these not of a permanent character, while the rich vegetation on the open downs, which had excited the admiration of Sir T. Mitchell, on his discovery of the country in a favourable season, had wholly passed away, leaving little but a bare surface of clay, the deep fissures in its surface giving evidence of long-continued drought." Only at one or two points did Mr. Gregory see anything approaching to a fine river, although in his diary on the 21st of April, 1858, he writes that some good reaches of water were passed. It would seem that the nearer the centre of the continent is reached, the greater the tendency to droughts, although they are considered periodical; but it is clear that if steam navigation is to be carried on in the Australian rivers to any great extent, it will be necessary to employ steamers of very light draught.

THE SMITHFIELD CLUB SHOW.

(*Continued from page* 25.)

B. Samuelson, of Banbury, exhibited his well-known turnip cutter, which obtained the first and only prize at Chester; as also a new American reaper, improved by himself. This reaper is self-raking, and, by simple mechanism, leaves the cut grain in sheaves ready for binding, clear of the track of the machine. It is said to work well with one man and two horses, and, at an ordinary walking pace, to cut 5 feet wide and clear 1¼ to 1½ acres per hour. Its low price is a recommendation.

Holmes and Sons, of Norwich, exhibited their very recently-constructed portable seed-sheller, which received special award at the Cardiff meeting, and which has an entirely new arrangement of dressing apparatus. The shelling-barrel is placed under the dressing apparatus, and the power applied close to the ground, which causes it to work very steadily; the seed passes from the shelling-barrel into elevators, so as to be delivered into the dressing apparatus, which, being placed above, allows all the hard hulk being delivered into the hopper of the shelling-barrel, to be passed through again, so that no portion has to be lifted a second time to the feeding-hopper. This machine is adapted for 7, 8, or 9-horse engines. Messrs. Holmes also exhibited their very well-known manure-distributors, which have received eight or ten prizes. The delivery barrels of these machines are made entirely of wrought iron. The scrapers being hung from the top, and being made to clean four deliverers, each one separately has the whole weight of the scraper, thus saving a considerable weight of iron. The machines are also fitted with Messrs. Holmes' "semi-lateral" wheel-stirrers, which are moved without extra gearing or crank action.

Cottam and Co., of Winsley-street, Oxford-street, exhibited, amongst their usual assortment of stable fittings, &c., some cast-iron dairy buckets, enamelled on the inside, and apparently well adapted for the use intended.

George Robinson and Sons, of Barton-on-Humber, exhibited their improved and patented clod-crusher roller, the distinguishing feature of which is its non-liability to wear sideways. This is prevented by making the bushes or naves twice the width or length of the outer disc or periphery. By chambering the bushes, twice the bearing surface is given to the spindles, besides receptacles for grease being provided for keeping the spindles lubricated. The discs or rings are so constructed as to split the clods instead of burying them in the ground.

Priest and Woolnough, of Kingston-on-Thames, exhibited a new "pony"-drill for market gardeners and seed-growers, which is sold for ten guineas, and seems well-suited for those farming a small quantity of land; all kinds of grain or seeds being capable of being drilled by it as by an ordinary drill. We may also mention Rowley's Patent Blast Drill, exhibited by this firm, and intended for protecting the turnip crop from the fly, &c. This operation is with great difficulty, and very imperfectly, performed by hand, as the fly usually shelters and feeds on the under-side of the plant, where it is almost impossible to apply lime or other composition. The blast-drill overcomes the difficulty; as, by it, lime, soot, &c., are thrown by a powerful blast by means of fans or flyers upon all parts of the plant, covering both the under and upper sides of the leaves. The insects are drawn by the in-current into the fan, and are destroyed by being mixed with the lime or other substance. It is more than probable that some substance may be discovered by which, with the help of the blast-drill, the diseases of the potatoe may be effectually arrested; but there are very many purposes besides those named for which this implement can be used with great advantage, such as for light top-dressings to crops. Soot or guano distributed over turnips, especially when succeeded by a shower of rain, has been found to be very beneficial.

A. Lyon, of Windmill-street, Finsbury, exhibited, or rather intended to exhibit, his "noiseless" sausage cutting and making machine; but, owing to some unaccountable mode of classification adopted by the committee of the show, sausage and washing machines were ordered to be put out of the way, as not being strictly of an agricultural character, although barometers and butter prints were not excluded, nor was a certain washing machine, because it happened to be called a "flax-washer." Indeed, the sausage machines are intended and made really suitable for preparing food, both for poultry and pigs; and, therefore, in every sense of the word, agricultural. Churns were also exhibited in abundance, as well as egg-whisks, as indeed everything might consistently be which relates to the preparation of food for man or beast. By one of Lyon's large machines, that is, one 16 inches square, 57 lbs. of meal was cut in 25 minutes at a public trial in Newgate market. The small machines sold for 30s. cut and fill 10 lbs. of meat in a quarter of an hour.

Hill and Smith, of Brierly-hill Works, near Dudley, exhibited their improved pig-feeding trough, with shifting divisions for feeding any number of pigs, and giving them accommodation suitable to their ages, sizes, or dispositions. They also exhibited their "continuous" fencing, 25 miles of which have been recently fixed up on the London and North-Western Railway. This fencing is constructed of flat bars nicked out to fit the uprights, and then keyed in place, making the whole very secure; the depth of the flat bars preventing them from being easily bent, offering as they do their edges in the direction in which they are most likely to meet with rough usage.

James Tree and Co. (Charlotte-street, Blackfriars-road), exhibited a great collection of Ewart's cattle gauges—half-a-dozen varieties—by means of which, combined with a little judgment, the carcase weight of oxen may be computed with great accuracy from their dimensions, and that of sheep and swine from their weight alive. We notice this instrument not on account of its novelty, but rather from its great utility, and because we have reason to believe a "slide rule," which the cattle guage resembles, is looked upon as a mysterious instrument of torture by a very large class of graziers and agriculturists. The most approved method of estimating the weight of cattle appears to be to guess at it, and any aids to the formation of a correct judgment are looked upon with supreme contempt. This may be accounted for partly by the fact that without some judgment being exercised, the cattle gauge would not be very accurate in its deductions. A man must know whether an ox be "half," "moderately," "prime," or "extra" fat, as also whether it be well or ill-bred before he can estimate its weight correctly, even with the aid of the gauge; for it appears that beasts of the same dimensions may vary from 64 to 97 stones, according to their breed, fatness, and sex. On this account there are nine different index points on the scale of the guage to every pair of measurements, but when the guage point is decided upon, which every grazier can readily satisfy himself about, the weight of the beast may be very accurately arrived at by the use of the gauge. In the case of ten beasts measured and weighed at the show, and whose weights varied from 57 to 132 stones, the average difference between the estimated and actual weights was only about three per cent., some of them agreeing to within a single pound. This degree of accuracy, it is needless to say, is very rarely, if ever, arrived at by the guessing process. The modes of using the cattle guages are popularly explained in a book of instructions sold with them. We may also notice a very useful instrument for agriculturists, the "garden microscope," said to be "adopted" by the Society of Arts, and which is sold complete for 20s.

Hely and Co. (the Cosmopolitan Glass Company), of 206 Oxford-street, exhibited amongst a very great variety of architectural, horticultural, agricultural, scientific, and domestic glass wares, a new milk test, by which its quality can frequently, if not always, be accurately determined. For the provinces these tests may answer well, but we doubt if London milkmen will be much affected by them, being accustomed with their milk to make up in quantity, that is, in consistency, what it wants in quality. We would, however, recommend the milk test to every good housewife, as were it used *bonâ fide* "skim" could never be taken for the genuine article; in other words, "new milk from the cow" be confounded with that from the "cow's tail."

T. Wheeler and Co., of Oxford, exhibited their "Oxonian knuckle" washing machine, which, as its name signifies, attempts the cleansing of linen by an action closely resembling that of the knuckles. The machine consists of a revolving drum, having upon it half-round ridges running parallel to the axis, and a series of floating discs, which revolve at right angles to the drum. The clothes are carried round the drum and between that and the floating discs or "knuckle rubbers." Wet sheets of paper, and consequently muslin or other fine textures can be passed through the machine without damage. The form of the machines may be varied, the rubbers being sometimes fixed in horizontal frames, the upper one of which is made to move to and fro by means of a winch handle. It is not a little curious to see very delicate articles passed through these machines, which, when at work, appear admirably calculated to tear to fragments the strongest material. The fact of the discs floating, however, and thus readily giving way to the slightest pressure, satisfactorily accounts for the real delicacy of the work. The principle of the machines seems most ingenious, and we think they will be found formidable rivals to the celebrated ball-washing machines.

F. Edginton, of Northampton, exhibited tents 12 feet square, which are sold for £8, and constructed so as to dispense with the ordinary central pole. This is a great improvement, and renders a small tent on this plan as convenient as a much larger one on the old one.

In noticing Wallis and Haslam's stand we omitted to mention that they were manufacturers of Robey's patented beater for thrashing machines, which consists simply of a bar of iron, having semi-globular indentations made in it on one side, which, of course, produce corresponding projections on the other. These projections, as they wear, may be readily set up to the requisite height.

NEW FIRE ENGINE.—On Thursday, January 6, a trial of a new fire engine, constructed on the principle of Mr. Robert's pumps, (illustrated on another page) took place at the anchor and cable works of Messrs. Brown, Lenox and Co., Millwall. The result was highly satisfactory. We shall illustrate the engine shortly.

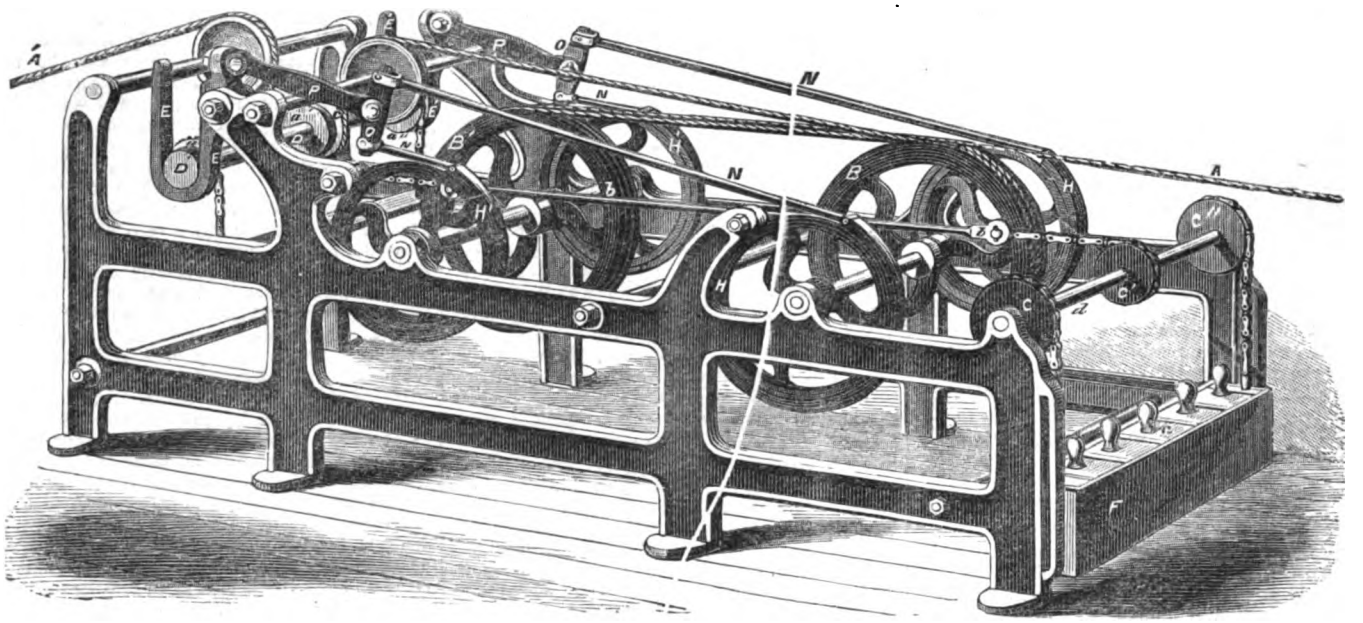
MOXON, CLAYTON, AND FEARNLEY'S APPARATUS FOR PAYING OUT TELEGRAPH CABLES.



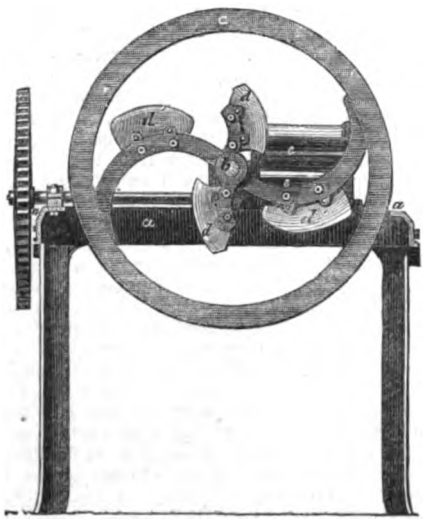
MOXON, CLAYTON, AND FEARNLEY'S APPARATUS FOR PAYING-OUT TELEGRAPH CABLES.

MESSRS. Moxon, Clayton, and Fearnley, engineers, of Blue Pits, Lancaster, have devised a most ingenious and effective apparatus for the purpose of preventing undue strain upon telegraph cables during the paying-out of the same. They so arrange the paying-out machine that as soon as an excessive strain is exerted — that is, a strain exceeding any given amount decided upon as the maximum strain consistent with safety — the breaks are slacked up and the cable allowed to run out without receiving any additional strain. That their apparatus will effect this object there can be no doubt in the mind of any one who understands its action. This we will now endeavour to make plain:—

The above engraving is a perspective view of a model of the improved machine. *A A'* are the two opposite ends of the cable passing round the paying-out drums, *B B'*, several times, and thence to the pulley, *C*, which runs loose on the shaft, *D*. This shaft carries three other pulleys, *a a' a''*, which are keyed upon it; and its enlarged ends, *D'*, rise and fall between the two upright arms of the bent levers, *E E'*. Connected to, and leading partially around the pulleys, *a a''*, are chains, the other ends of which lead down to a fixed part of the framework; and a third chain, having one end connected similarly to the pulley, *a'*, has its other end attached to one end of the rod, *b*. The other end of this rod has attached to it a chain, *c*, the other end of which passes around and is connected to the pulley, *c'*, on the shaft, *d*. This shaft also carries the pulleys, *c* and *c''*, which have connected to them chains, passing down to a box, *F*, carrying as many weights, *G G*, as may be desired, or found necessary. *H H*, *H' H'*, are the break-drums, keyed on the same shafts respectively as the paying-out drums, *B B'*. *L* and *L'* are the breaks, one end of which is attached to the brackets *M* and *M'*. The other ends of the break straps are attached to the connecting-rods, *N N*, the said rods being connected at their opposite ends to the cross links, *O O*, the centre rods, *P P*, passing through the upper ends of the arms of the levers, *E* and *E'*, which turn on a pin or stud attached to the frame-end Q. After the weights, *G G*, have been placed at the end of the chains to give to the cable a certain amount of strain, should any irregularity in the strain of the cable take place, the regulator acts instantly; the pulley, *C*, on the shaft, *D*, rises and carries with it the pulley, *a'*, on which the pull of the weights, *G G*, comes. Before this takes place, the weights, *G G*, draw against the levers, *E E'*, and at the upper ends of these levers is attached the connecting rods, *N N*, which are connected to the breaks, so that a given friction is put on the breaks; but when, as we have said, the friction becomes too great, the ends, *D'*, of the shaft, *D*, travel nearer the fulcra of the levers, *E E'*, and thus diminish the strain on the breaks. Instead of the weights, *G G*, before described, which would be very liable to prove objectionable in a rough sea, the inventors sometimes apply springs, in other cases they retain the weights, but cause them to work in suitable guides.

GARDNER'S CHAFF-CUTTING MACHINES.

THE accompanying engraving illustrates the improved chaff-cutting machines of Mr. Joseph Gardner, of Banbury. The figure is a front elevation. The chief object of this invention is to



economise the power required to drive the machines by the use of a peculiar adjustment of the knives, so that, instead of each cut being completed by one and the same knife, or by two knives acting in succession from opposite sides of the material under operation, two or more convex knives constituting a set act in succession, and in the same direction to make one cut through the material fed to the mouth-piece. *a*, *a*, is the main framing of the machine, carrying at its upper part the bearings for the shaft, *b*, of the fly-wheel, *c*, to the arms of which the knives, *d*, *d'*, are bolted. Two sets of these knives are shown as applied to the fly-wheel arms, but more or less may be used, if thought desirable, according to the diameter of fly-wheel employed. The knives, *d*, have a radius that permits of their passing through and cutting about one-half the breadth of the feed presented by the mouth-piece, *e*, to their action, and the knives, *d'*, have a radius that enables them, as they revolve, to complete the cut through the material fed up to the mouth-piece. The knives may be mounted on the same or on opposite sides of the fly-wheel or disc employed to carry them; the feed motion, whether intermittent or continuous, being adjusted to suit the action of the knives. Whether the knives of different radius be fixed on the same or opposite sides of the fly-wheel or disc, Mr. Gardner proposes to set them in different planes; and in order to render them more efficient in their action, he provides a stepped mouth-piece, or a mouth-piece with one part projecting beyond the plane through which the knives of small radius move. By this means the material, while under the action of the knives of larger radius, is held more firmly up to the cut than it would otherwise be. The invention is patented (No. 1,083, 1858).

CONCUSSION FUZES.—In the *Times* of yesterday, under the head of Naval and Military intelligence, Colonel Wilford, R.A., in his lecture at Woolwich, is made to say:—The concussion fuze of the late Quarter-Master Freeburn, is the best. In the official letter to me, signed Hardinge, lately recorded in your Magazine, he is called Captain Freeburn. The intelligent mechanics who read your Magazine, and who, from the teachings of their mental labour, learn to compose and reason by *induction*, will be anxious to know the difference between my concussion fuze of 1841, which was in 1843 reported by the Select Committee at Woolwich, to be "simple, safe, and efficacious, being well adapted for horizontal fire with high velocities," and that which Quarter-Master Freeburn adopted in 1845, while I was lying on a sick bed in Dublin. Will Colonel Wilford at any time be pleased to favour the public with a drawing of the Freeburn fuse? J. NORTON, Park-villas, 4th January.

AN IMPROVED METHOD OF DRYING BUILDINGS, &c.

WE bespeak the careful attention of our readers to the following practical remarks "on some economic applications of the chloride of calcium," by Mr. Desmond G. Fitzgerald, one of the most observant and enlightened of our rising chemists:—

It might well be a matter of surprise that the chloride of calcium, so valuable an auxiliary in the laboratory for depriving gases of their hygrometric moisture has not found many important applications of general practical utility. Cheap, easily prepared, free from all deleterious emanations, and lasting indefinitely for the purpose required, its powerful attraction of moisture gives to it a dissiccating property which in many instances may advantageously and economically replace the combustion of fuel. In drying the walls of newly-built houses, for instance, a few pounds of this substance, contained in iron pans, may obviate the expenditure of many hundred-weight of coals, the combustion of which acts very inefficiently for the purpose in view. In the usual condition of our atmosphere, the draught of a very large fire can remove from the walls of a newly-plastered room but a comparatively small amount of moisture, the radiated heat being almost ineffectual. But pans of the deliquescent salt, placed in various parts of the room, rapidly abstract the moisture of the air, which, in its dry condition, as rapidly removes the water of the porous plaster. We recently had occasion to point out this fact to an eminent builder, who probably has been the first practically to apply the chloride of calcium to an economic purpose. The iron pans are removed from time to time, as the salt becomes saturated with water, and this is driven off by the application of heat, which is continued until the salt fuses. It may then be broken up with a chisel, and again made use of.

Many similar applications of this substance suggest themselves. In wet weather it may serve the laundress as a substitute for expensive fuel by drying linen, &c, suspended in a close room. It is important that the salt should always be contained in a vessel to which heat may readily be applied. An ordinary fire place answers very well the purpose of drying and fusing the dissiccating agent.

The chloride of calcium may be prepared by adding muriatic acid to chalk or limestone in the open air until the effervescence ceases, and then evaporating and fusing the salt by the aid of heat. 100 parts of it may be made to absorb 124 parts of water from the atmosphere. It has been employed for freeing oil of turpentine and alcohol from water.

We will proceed to point out an important application of the chloride of calcium in the manufacture of tobacco. The principal cause of the inferiority of home-made cigars to those of foreign manufacture is the difficulty of removing the water employed in "making up" the leaf after its exportation. Many varieties of tobacco will not "stand" the application of moisture, losing their fragrance, and becoming friable by fermentation, whether the moisture be allowed to remain or is partially driven off by heat. In this instance, the rapid abstraction of water, attended with a *reduction* rather than *increase* of temperature, is peculiarly valuable. We have, on several occasions, found cigars of English manufacture kept for several weeks in an atmosphere perfectly dried by means of chloride of calcium, to be perfectly equal to the high-priced cigars of foreign make. The plan we adopted was to keep the newly-made cigars in a chest fitted with a tray constructed of metal, and having a perforated cover; the tray being filled with fragments of fused chloride of calcium.

The judicious employment of this agent may often prove extremely beneficial in a sanitary point of view. A moderately dry atmosphere is the best preservative in cold weather against sudden chills, the effects of which, especially in the case of a weakly constitution, are so dangerous. The result of passing from a sleeping apartment charged with heated vapour—condensing upon the window-panes, and preventing a free perspiratory evaporation—into an atmosphere which quickly chills the skin and closes the relaxed pores, too often manifests itself in inflammatory symptoms, especially upon the lungs. The air of such an apartment may be freed from unwholesome moisture to any determinate extent by the exposure of a proportionate surface of the chloride of calcium. We recommend this agent to the attention of the medical profession; feeling confident that its employment would, in very many cases, obviate the painful concomitants of a trying and changeable winter.

DESMOND J. FITZGERALD.

SHIPPING STATISTICS.

(*Continued from page* 24.)

ON the important question as to the extent to which the ordinary smooth-water trial of a steamer affords a criterion of the general average performance that may be expected of the vessel at sea, this committee has not been able to obtain such an extent of returns of the comparative smooth-water trials and sea performances of the same ships as enable them fully to respond to this part of the inquiry, and they refrain from expressing any speculative opinion, because they have adopted the principle which they desire to recommend to the notice of the British Association, that shipping improvement is to be discovered by statistical record and analysis of the constructive elements of ships that have practically shown themselves to possess good sea-properties, rather than by assuming the mere theories of opinionative speculation, from whatever source such opinions may emanate; in short, that experience of actual performances at sea, statistically recorded and utilised by being made the basis of comparison, is the most reliable base on which to construct an inductive system of progressive improvement in naval architecture and marine-engine construction. This committee, however, have much satisfaction in being enabled to commence this inquiry by recording the sea-performance of the before-mentioned vessel *Bremen*, on a passage from Bremen Haven to New York and back, during the months of June and July last, during the whole of which passages indicator cards were frequently taken, and the indicated working power of the engines ascertained. On the out passage the mean displacement was 2,878 tons, the mean indicated horse-power was 1,078, and the mean speed 10·28 knots per hour, giving a co-efficient by the formula referred to = 301; but on the return passage the mean displacement was 2,990, the mean indicated horse-power 1,010, and the mean speed at the rate of 11·92 knots per hour, giving a co-efficient = 318. Hence, the mean co-efficient of the out and home passage = 276, being about 13 per cent. below the co-efficient (319) obtained on the smooth-water test-trial of the ship. The state of the weather and the sea was also recorded daily; it appears to have been adverse on the out passage, but favourable on the home passage. The committee are, therefore, of opinion, that by following up this course of statistical record of the smooth-water trial and subsequent sea-performances of ships respectively, a tabular statement might be compiled, showing the probable ratios of the co-efficients of smooth-water and sea-performance, corresponding to the various rates of speed for which steamers may be respectively powered, whence the smooth-water test-trials of ships may be made available as approximately indicative of the sea-service capabilities of ships as respects their dynamic properties.

Such are the statistical data of the constructive elements and dynamic capabilities of the *Bremen*, and if all steam-vessels engaged in the mercantile transport service of Britain were equally effective as respects the mutual relations of displacement, speed, and power, that is, capable of producing a co-efficient of dynamic capability = 319, by the formula referred to, it is probable that the prime cost expenses of steam-ship transport per ton weight of cargo conveyed on long passages would, on the aggregate of the foreign trade of Britain, be reduced not less than 25 per cent. as compared with the prime cost expenses incurred by steam-vessels of the average dynamic capability in present use.

The effect of improved type of build on the economy of steam transport per ton weight of goods conveyed, is such as shows the inquiry to be of vital importance in connection with the management of steam shipping affairs.

The public importance of improved type of build in a national point of view (for it is the public and not the shipowners who ultimately bear the brunt of expensive transport service), may be judged of from the statistical fact published by the Board of Trade, that no less than 899 steam-vessels (of which 511 are sea-going ships) were employed on the commercial transport service of Britain in 1857. The ratio in which the transport service of the country is performed by the aid of steam appears to be constantly on the increase, and as it is to be expected that mercantile competition will always cause the cost of freight on the general aggregate of the trade of the country to be proportionally ruled by the prime cost expenses that may be actually incurred in doing the work, it appears manifest that the public economy dependent on the general realization of shipping improvement, is a consideration that involves public interest to the extent of millions sterling per annum.

To demonstrate the vast importance of this subject an appendix has been compiled from the returns of the Board of Trade, to show the amount of trade between the United Kingdom and foreign countries during the year 1855. This compilation shows that the tons weight of cargo actually carried in the foreign trade of the United Kingdom in the year 1855 amounted to—

Imports.....	6,254,259 tons.
Exports.....	8,370,363 „
Total.....	14,624,622 „

Nearly 15 millions of tons weight of sea-borne cargo conveyed at probably 25 per cent. extra cost beyond what would be incurred if ships of the high order of dynamic merit exemplified by the *Bremen* were only and exclusively employed.

By aid of the appendix, showing the amount of trade between Great Britain and all foreign countries respectively, parties conversant with shipping affairs will be enabled to estimate approximately the gross amount annually involved in the goods transport service of Britain. Thus public interests require that the statistical records of shipping should embrace such data as will be availably conducive to shipping improvement, by affording the means of approximately estimating the dynamic capabilities of ships, whereby every ship-constructor and ship-owner, and the directors of steam shipping companies, may be enabled to test the dynamic merits and condition of their ships respectively; a system which would gradually lead to the adoption of such types only as develop a high order of dynamic duty, and would obviate some of the most serious hazards to which private and public interests are now exposed from vessels being employed on commercial and postal services for which they are not fit.

Only let it be publicly known, as exemplified by the *Bremen*, that steam-ships and their machinery may be so constructed, that on being subjected to a test-trial the cube of the speed in knots multiplied by the square of the cube root of the displacement, and divided by the indicated horse-power, ought, in the present day, irrespective of future improvement, to produce a quotient or co-efficient of dynamic duty equal to the number 319, and that the co-efficient deduced from the rule thus enunciated constitutes (*ceteris paribus*) a criterion of the cost price at which steam-ships perform their work, and we shall then soon find that this test of dynamic merit, or the numerical co-efficient deduced therefrom, will enter into the calculation of the pecuniary value of steamers to such extent, that ships of a low order of dynamic capability will not be built because they will not sell.

(*To be concluded in our next.*)

ROBERTS'S SHIPS' PUMPS.

FIG. 1.

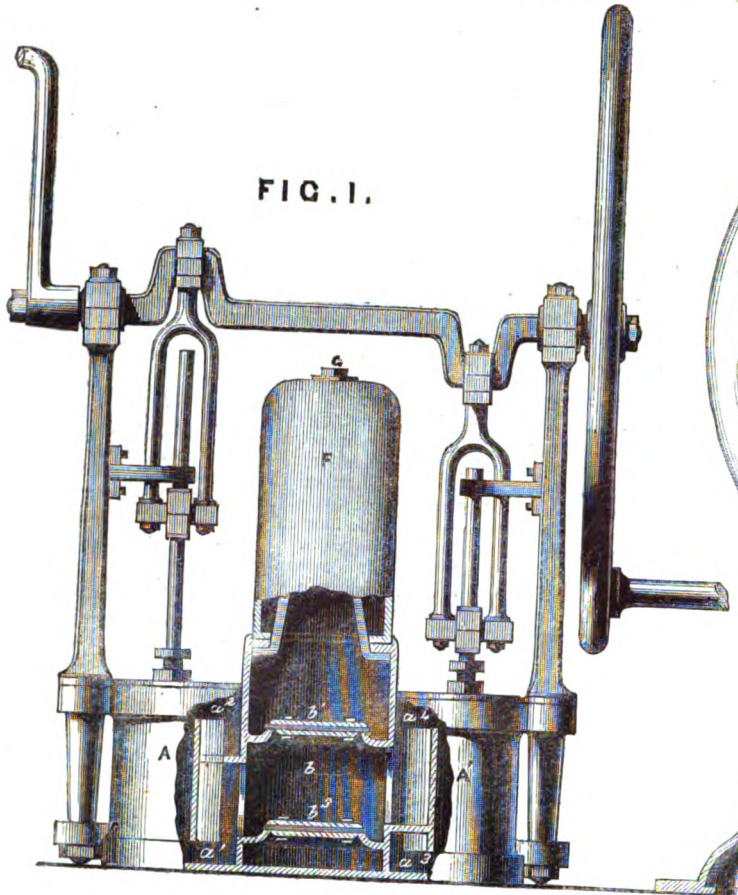

FIG. 2.

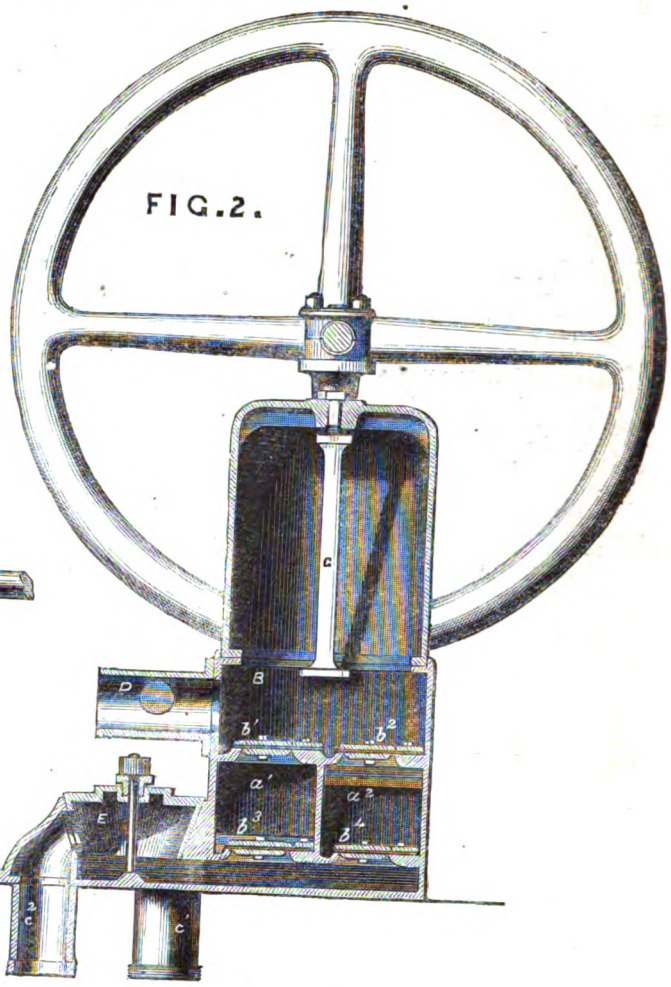
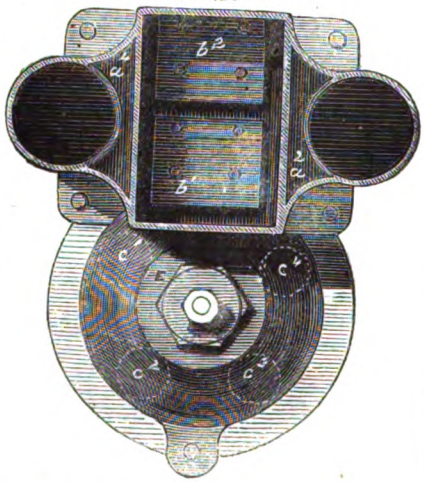


ROBERTS'S AND DOWNTON'S SHIPS' PUMPS.

WHEN we undertook—as we did some weeks since—to publish an article of our own upon the relative merits of the Downton pump, which has been so long in use in the navy and elsewhere, and the new pump which Mr. Roberts has lately brought forward, and which has been favourably reported upon to the Admiralty, we undertook a task which is neither easy nor pleasant. A writer knowing very little of either pump might readily satisfy himself in pronouncing an opinion, and another knowing very much about both might do the same; but a writer having a necessarily imperfect knowledge of the two machines, in so far as their actual operation is concerned—which is our case—must find, and must expect to find it difficult to deal with the subject to his entire satisfaction. This will be considered, we know, a damaging admission by some persons, but it is one which we make without hesitation, and which sensible men will construe properly.

Being perfectly well aware that sound practical men attach infinitely more importance to matters of fact than to the mere opinions of the ablest editors in the world, we have, in the first place, been careful to present them with illustrations of the actual constructions of the pumps themselves. The Downton pump, although in very general use for many years, has never before, we believe, had its internal construction publicly described; and Mr. Roberts's pump, although kept less secret than the other, is more perfectly illustrated in the annexed engravings than it has hitherto been. Upon the merits and defects of the respective modes of construction of the two pumps the reader can, therefore, judge for himself. In the

FIG. 3.



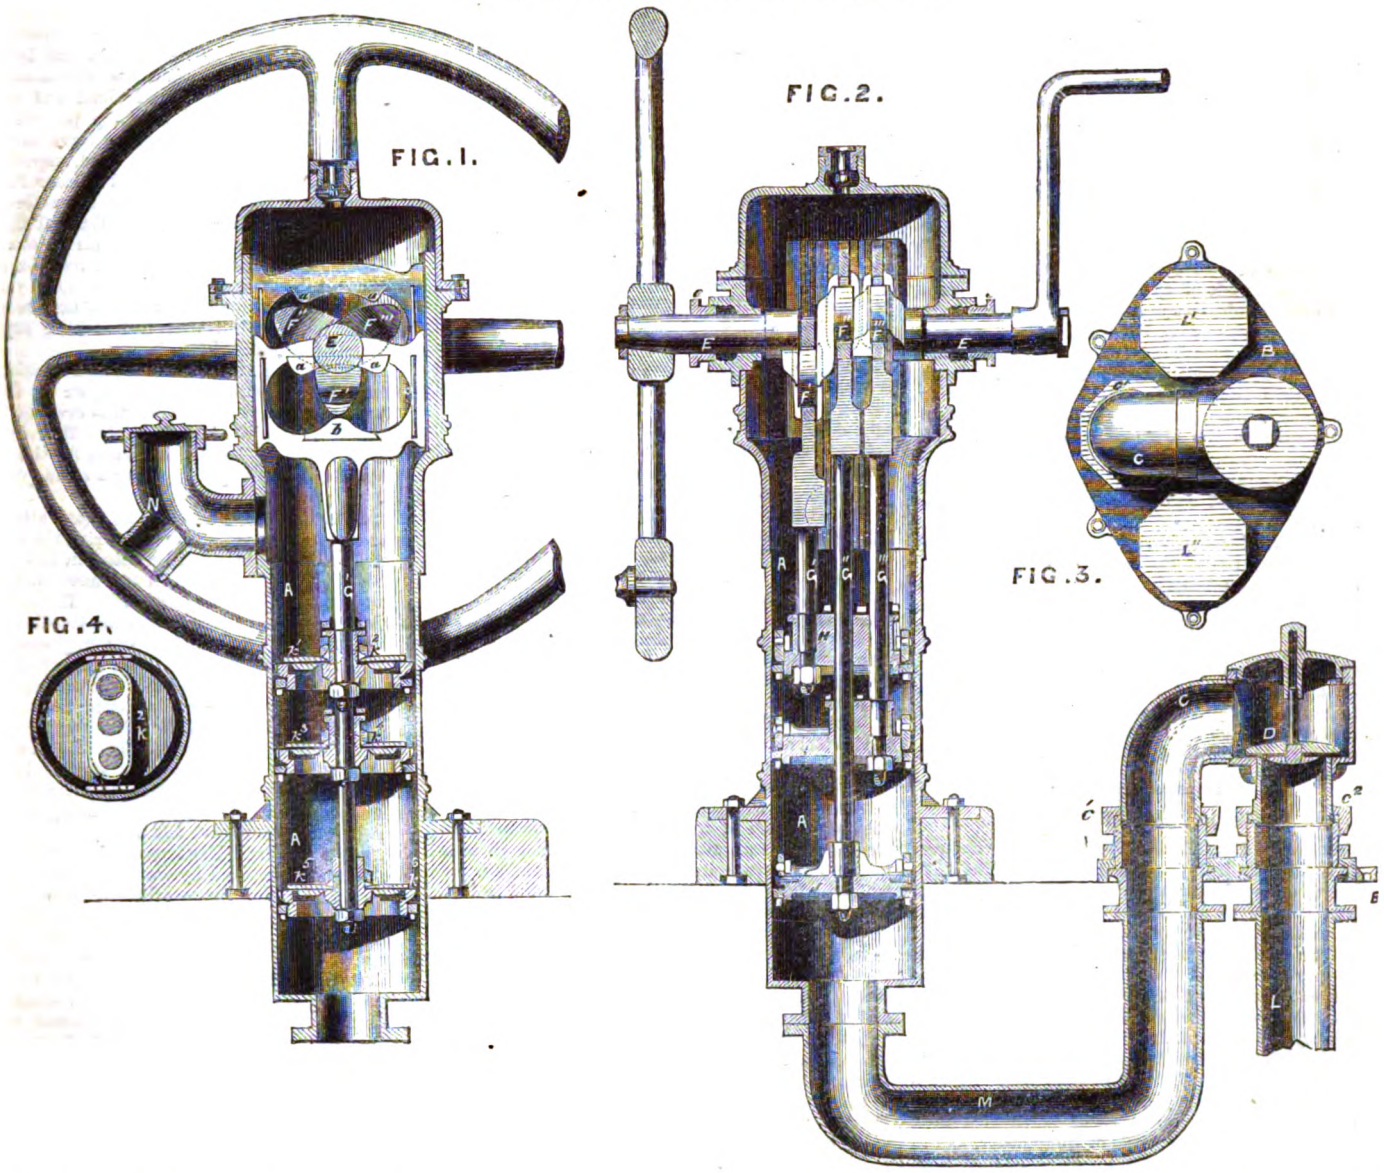
engravings of the Downton pump, fig. 1 is a section through the centre of the pump; fig. 2, a section through the line of the crank-shaft and suction-plate; fig. 3, a plan of the suction-plate, with three suctions; and fig. 4, a plan of the bucket, showing the manner in which the bucket-rods go through. *A A* is the cylinder; *B*, the suction-plate; *C*, the goose-neck; *D*, the foot-valve; and *E*, the crank-shaft. F^1 F^2 F^3 are cams, and G^1 G^2 G^3 are the rods. *H* is the upper bucket, worked by the rod G^1, at its side, having two stuffing-boxes for the rods G^2 and G^3 to work through. *I* is the middle bucket, worked by the rod G^3, also at its side, and having one stuffing-box in the centre for the rod G^2 to work through. *J* is the lower bucket, worked from the centre. k^1 k^2 k^3 k^4 k^5 k^6 are the valves, and *L* is the suction-pipe, leading to the hold. *L' L''* are cap-nuts, covering other suction-pipes, not shown in the section. *M* is a pipe leading from the suction-plate to the pump. *N* is the delivery-nozzle. c^1 c^2 are fly-nuts, that have to be taken off when the goose-neck is shifted; *e e* are stuffing-boxes, to make the crank-shaft air-tight.

In the engraving of Mr. Roberts's pump, fig. 1 is a view of the pump, having the suction-plate and part of the front removed to show the valves and water-passages; fig. 2 is a section through the centre, or nearly so; and fig. 3 is a plan of the pump, having the top removed to show the valves, &c. *A* and *A'*, the cylinders; *B* is the valve-chamber, having a partition, *b*, shown in fig. 2. *C* is the suction-chamber; *D*, the delivery; *E*, the plug in the suction-plate; *F*, the air-chamber; and *G*, a bolt for holding the air-chamber down. a^1 a^2 a^3 a^4 are passages leading to the cylinders; b^1 b^2 b^3 b^4 are the valves; and c^1 c^2 c^3 c^4 are suction-pipes leading to the hold, the sea, &c. These figures are engraved from the pump lately tried at Woolwich.

The manufacturers and supporters of these pumps have conducted a prolonged and bitter controversy on their respective merits, and have devised a most ingenious arithmetical labyrinth, into which we by no means purpose entering. For, in our judgment, the method of conducting comparative trials of pumps now in vogue, and pursued during the late trials at Woolwich, are by no means of a satisfactory character. How is it to be supposed that any reliable result can be ob-

Digitized by Google

DOWNTON'S SHIPS' PUMPS.



tained by merely clapping a half-dozen or dozen men upon the handles of first one pump and then another, and observing the height to which the water is thrown, or the time occupied in transferring a body of water from one vessel to another? Who is to tell whether the work done by the men upon the one pump is equal to that done upon the other? The mere glance of an officer—to say nothing of bribery, in its many forms—may mar the most careful experiments made by such means. Nor is the mere observation of the number of strokes made per minute sufficient to correct the results by. An average number of strokes may be made with a pump, and yet the volume of water passed through the machine in one minute may be very different from that passed through in another. For, in order to get like results in equal times the velocity of revolution must be uniform throughout the periods. If some pumps are run, for example, at very high speeds, they will deliver less water than when the speed is moderate. The only truly satisfactory way to test pumps comparatively is to put some uniform hydraulic or other like force upon them for equal periods. And if manual trials of pumps are in themselves unsatisfactory, newspaper reports of their results are much more so. We doubt not that the official trials lately made and reported upon at Woolwich have a certain decided value; but until their results, as officially reported, are before us, we are in no position to discuss the relative per-centages of gains and losses.

Apart from the arithmetical questions in dispute between Mr. Roberts and the gentlemen who write on the opposite side of the subject, there are others in respect to which, we think, some want of fairness has been shown. In the first place, Mr. Roberts brings against the Downton pump the facts that it is not a portable pump, and that it cannot be itself used as a syphon for running water into the hold to extinguish fires in cargoes. Now, of the Downton pump, as at present fitted in Her Majesty's ships, these statements are quite true, and Mr. Roberts has an undoubted right to adduce them. But, when the alleged deficiencies are urged as important defects, which it is of immense importance to get rid of, and the rival pump is extolled because it is portable and can be used as a syphon, some risk is run of falling into unfairness; because portability and a capability of syphonic action, are qualities with which the Downton pump can be supplied if desired, and the want of them is incidental, and not necessary, to its use. We do not wish to imply that Mr. Roberts is without great credit as the first who has supplied these qualities; on the contrary, he has here a just ground for recompense. But, since the makers of the Downton pump are prepared to supply these qualities without in any way changing the essential features of the pump, it is not right to push this matter very far, especially as the qualities themselves would be of use in exceptional cases only. On the other hand, the theoretical considerations adduced by "J. S. H." in antagonism to the Roberts pump, have been pressed too far. As theoretical considerations, and as guides to practice, they are of the utmost importance; but when they are urged as of themselves conclusive evidence against the utility and value of a machine, they are pushed beyond their sphere. It is doubtless desirable that the form and velocity of the water should be preserved as nearly uniform as possible in its passage through any hydraulic machine, whether pump or not; but curious facts of a contrary tendency are observable. For example, if the valves of a pump be examined (through a glass side, or otherwise) while the pump is in action, it will be found that the internal forces are of such a character that the valves seldom open very considerably, however free to open they may be. The fluid, by preference, passes through a small rather than a large

Digitized by Google

channel—a fact which no theoretical reasoning would, we think, have led us to, and which should teach us to apply theoretical truths, even when deduced in the first place from experiment, with moderation. And beside this, the Downton pump is open to objection on the self-same ground.

For our own parts, we feel that it would be mere pedantry to pronounce definitively upon the merits of the two machines. The verdicts of the many practical men with whom we come in contact, who have used the Downton pump for a series of years, and of others who have now had experience with Mr. Roberts's, are variable There are features in the former which, on the face of them, appear very objectionable; such as the rods of two out of the three buckets or pistons being out of the centre, the use of cams and cross heads, or frames, in the manner shown in the engraving, &c.; but then, if these arrangements are not found, in practice, to be great evils, it would be fallacious to pronounce them such. And, again, there are features in the latter (*i. e.* the Roberts pump) which also appear objectionable—such as the tortuous nature of the fluid passages pointed out by "J. S. H;" but if these again are not found, by experiment, to be evils, it would be equally fallacious to insist upon them.

To conclude:—It is satisfactory to know that the practical use of the new pump in the Royal service, to a sufficient extent to test its merits under all circumstances, is either decided upon, or likely to be decided upon speedily. This is a perfectly legitimate, and indeed a necessary result of the reports made by the officers at Woolwich Dockyard, and ought, we think, to give offence to none. Every good ship's pump is a valuable thing, and if both of those under consideration are good, there will doubtless be found uses for both.

INDIAN ITEMS.

THE *Indian Field* directs attention to the resources of India as an iron-producing country. The *Field* hears, on good authority, that the best Indian iron can be manufactured into rails and sold at Calcutta at £4 per ton; while English rails cannot be sold at the same market for less than £8 per ton.——A "spark baffler," designed to prevent the escape of sparks from the funnel of a locomotive, has been tried on one of the Indian railways, by Captain Sim, deputy-consulting engineer to Government in the railway department, and some other gentlemen. The locomotive to which the baffler was applied drew a train comprising twelve open trucks laden with jute, wood-shavings, and a trifle of gunpowder, and in a twenty-four miles run not a spark escaped from the funnel of sufficient magnitude to ignite these highly inflammable materials. The invention emanates, we believe, from Mr. Gower. ——Sir William O'Shaughnessy, chief superintendent of electric telegraphs in India, reports that the Ceylon line has been much injured by violent gales; and writing on the 21st of November stated that it could not be brought into good working order for a month or six weeks. The English cable for the submarine telegraph between Kotree and Hyderabad has arrived, and Mr Smith, superintendent of electric telegraphs in Scinde and the Punjaub, has proceeded to Roree to lay it down. The communication between Roree and Sukkur is to be carried on by means of posts from Roree to Bukkur and from Bukkur to Sukkur. Active exertions are being made to complete the line between Hyderabad and Mooltan. The greater portion of the wire has been laid down at different places, and eight inspectors with their staff of workmen are engaged in carrying out the undertaking.——The extension of the Great Indian Peninsula Railway to Decksal, 65 miles from Poonah on the Bheema river, is almost ready for traffic.——Tenders are invited for the performance of the mail service between Bombay and Keamaree Bunder, Kurrachee, by efficient steamers, for five years, from Jan. 1, 1860.

PARIS NOTES.

(FROM OUR PARIS CORRESPONDENT).

MEASURE OF SPECIFIC GRAVITIES.—A new method of ascertaining and verifying specific gravities has been laid before the Academy of Sciences of Paris, by M. A. Meyer, who says:—"The present methods employed for ascertaining specific gravities are very exact, but complicated. In fact, the whole consists in facilitating the means of measuring exactly the volume of water displaced by any given body of which the specific gravity is to be ascertained. The problem," he says, "may be solved in the following manner:—After having filled a vessel with water, place therein the long leg of a syphon. When the water is quite at rest, plunge the body of which the specific gravity is to be measured into the vessel. The water displaced will escape by the syphon, and being caught in a receiver, will represent exactly the volume of the body immersed." The arrangement is spoken of as peculiarly applicable to the measuring of minerals and other substances which cannot be got into the hydrostatic balance.

SENSATION OF HEAT CAUSED BY CARBONIC ACID.—A communication has just been made to the Academy of Sciences of Paris on this subject. One of the most singular properties of this gas, says the report, is its decided effect upon the skin. All parts of the body that come in contact with it feel immediately an extraordinary increase of heat, which is not exhibited by the thermometer. A person placed in a room heated to 20° centrigade, and plunging his naked arm into a receiver full of carbonic acid gas, feels as though he had put his arm into something 15 or 20 degrees hotter than the air of the chamber. This property has been turned to account medically in thermal establishments where baths and *douches* of the gas, sometimes pure and sometimes mixed, have been administered to invalids, but we are not told with what effect. M. Boussingault says that in a trench of an old sulphur-mine in New Grenada, he was almost suffocated and thrown into a violent perspiration by this gas, the heat of which he believed, at the time, to be equal to 40°, but his thermometers, after being left an hour in the trench, only marked 19°, three degrees, in fact, less than the temperature of the surface in the shade. The Professor also felt a pricking sensation in the eyes from the effect of the gas, and he was assured by the miners that they almost all suffered from weakness, and that blindness was a common result of constant exposure to this gas.

PRODUCTION OF ALUMINIUM.—M. Corbelli, a French chemist, has discovered a more simple and economical mode than that heretofore practised, for the extraction of aluminium from clay. By his mode the metal is obtained directly from clay or argillaceous earth. The material is first washed free of all impurities and foreign matters, such as stones, leaves, morsels of wood, &c. Two or three ounces of it are then dried, and submitted to the action of acid, to get rid of the iron contained in it. For this purpose, M. Corbelli uses highly-concentrated sulphuric acid; but nitric, hydrochloric, and other acids have the same effect. The earth is dissolved in six times its weight of acid, the earthy matters are allowed to subside, and the clear liquid is then poured off. The residue is dried, heated to 450° to 500° centigrade, and afterwards mixed with 200 grammes (between six and seven ounces English) of yellow prussiate of potass, well-dried and pulverized—the quantity of the latter being increased or diminished in proportion to the amount of silex contained in the clay. To this mixture are added about five ounces of sea-salt, and the whole is placed in a crucible and heated until a white colour is produced after cooling. The aluminium is found at the bottom of the crucible.

WATER TELEGRAPH.—At a meeting of the *Club of the Scientific Press* the other day, a young engineer, named De Lucy, explained a plan which he had conceived of substituting tubes of water for electricity in submarine telegraphs. He proposes to produce his signals by means of percussion; each end of the tube being provided with a cistern of water, covered with very thin sheet copper or India-rubber. Of course a blow struck on the covering of one of these cisterns is very rapidly communicated to the other. Such an apparatus, established between Calais and Dover, would, it was said, transmit its vibrations in eighteen seconds, and between Ireland and America in half-an-hour. M. De Lucy proposes to record the vibrations by means of a lever moving a tracing-point against a paper band, moved by clockwork as in Morse's system. Professor Faure being present at the meeting, drew the attention of the inventor to the fact that General Morin had touched upon the subject in his *Leçons de Méchanique Pratique*, and had there recorded the fact that a tube of water more than 5,000 yards long had been used for signals on the London and Blackwall Railway, but that it had been superseded by the electric telegraph.

GAS-LIGHT IN RAILWAY TRAINS.—Portable gas has been introduced, experimentally, on the Paris to Strasbourg railway. A first-class carriage was lighted with it on the 10th instant. It was used with the ordinary lamps, and burnt for thirteen hours without interruption, giving a steady white light.

PEDO-MOTIVE CARRIAGE.—One more attempt has been made to enable people to drive their carriages without horses. The inventor, in this case, is a M. Salicès, a lieutenant in the navy, and the carriage is called *Barotrope-voiture*. The motive machinery consists of hand levers and treadles. An experiment was made the other day in presence of a number of scientific men, and the report is highly laudatory. It is said that the carriage ran well on stones, macadam, and up hill; that it performed at the rate of 14·530 metres (rather more than 15·700 yards) per hour, and that the exertions of the travellers were extremely light. It remains to be seen whether this new mechanical carriage will succeed where so many similar promising inventions have failed.

GILDING TEXTILE FABRICS.—Gold stuffs are generally manufactured by weaving gold thread, which renders the tissue stiff and heavy. M. Burot has just discovered a method of gilding stuffs by means of electrical agency. The piece to be gilt, whether made of silk or any other material, is dipped into a solution of nitrate of silver and ammonia; after remaining in this solution a couple of hours, the stuff is taken out, and, when dry, exposed to a current of pure hydrogen gas, which reduces the salt, and leaves the silver in a metallic state on the stuff. A silvered surface is thus obtained, which is easily gilt over by the usual galvanoplastic methods. Beautiful specimens of gilt and silvered lace were exhibited in London some five years since. They were of French origin, but the process was not made known.

WATERPROOF STUFFS.—The following process has just been published, for rendering clothes and all kinds of stuffs waterproof:—Take of gelatine and soap 1 lb. each, dissolve them together in 30 quarts of boiling water, and add by degrees 1¼ lbs. of alum; then continue the ebullition for another quarter of an hour. When the milky liquid thus obtained has cooled to the temperature of 122 degrees Fahrenheit, the stuff is dipped in and allowed to soak well. It is then taken out and left to dry, after which it is carefully washed and mangled. The process is explained as follows:—When the gelatine and soap are brought into contact with alum, the sulphuric acid contained in the latter converts the soda contained in the soap into sulphate of soda; the animal acids of the soap are thus set at liberty, and form with the gelatine a kind of jelly which is insoluble in cold water, and therefore renders the stuffs waterproof. This, however, is only the case with soap made with tallow.

NOTICES.

Numbers 1845 and 1846 of the MECHANICS' MAGAZINE original series), containing the paper read at the Society f Arts, Dember 15, 1858, "ON THE MODIFICATIONS WHICH HE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING HE PRESENT CENTURY IN RESPECT OF DIMENSIONS, FORM, LANS OF PROPULSION, AND POWERS OF ATTACK AND EFENCE," by one of the EDITORS of this Magazine, gether with the discussion upon the same, are still on le.

The MECHANICS' MAGAZINE will be sent free by post to l subscribers of £1 1s. 8d., annually, *payable in advance.* l st Office Orders to be made payable to R. A. Brooman, at t e Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column a charged at the rate of 6d. per line for any number of in sertions less than 13; for 13 insertions, 5d. per line; and fo 52 insertions, 4d. per line.

Each line consists of 10 words, the first line counting as tw o. Wood-cuts are charged at the same rate as type for th space occupied.

Special Arrangements for larger or Serial Advertisements. T ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can b received after 9 o'clock on Friday morning for the ensuing number.

TO CORRESPONDENTS.

☞ The practice of publishing a vast quantity of fictitious Notices to Correspondents has become so general in the cap journals, that the public, who are not in the secret, have come to consider it the duty of Editors to answer any and every question that may be put to them by readers. This cannot, however, be done in a journal like our own without entailing an immense amount of labour (often of a very unnecessary character) upon us. We, therefore, beg most respectfully to decline the task. But in order that our correspondents may not be deprived of all advantage in this respect, we shall, as a rule, publish such queries as may be sent in good faith to us, though not such as appear to be sent merely for the sake of giving trouble. To the published queries other correspondents will, we hope, reply, and their replies shall likewise be published. By this arrangement we shall save ourselves much inconvenience, and at the same time secure, we trust, to our readers all the information they may desire. All questions must be stated simply, clearly, and without circumlocution of any kind; and we shall feel grateful to those correspondents who kindly take the trouble to send such information by way of reply as they may possess. Mere questions of business we shall of course answer ourselves; but whenever calculation, reference to published works, &c., are necessary, we shall dispose of the questions sent as stated above.

CORRESPONDENT'S QUERY.

GENTLEMEN,—Will any of your readers be so kind as to inform a constant reader, in your next number, where a new metal can be had, which has been introduced to this country from France? It is a white metal, not so hard as copper, nor so soft as Brittannia metal, and is a nearer approach to silver in appearance than German silver. Also, if there has not been a patent lately taken out for cementing all kinds of metals. I should feel obliged by seeing the number and date of the patent in your journal. T. S.

RAFT SHIPPING.

MR. CHARLES ATHERTON, of Woolwich Dockyard, an officer of great experience, under date 10th January, 1859, addresses us as follows:—

Many suggestions have of late been brought before the public on the construction of gun-boats, mortar-boats, and floating-batteries, with a view to making them invulnerable; and I now beg to add my views on that subject. Why not make the floating body for such especial services up to the line of its load displacement a solid mass of material of such specific gravity lighter than water, that it shall not sink, however much it may be perforated by shot? It appears to me that a solid combination might be made of cork-shavings, light wood, saw-dust, rush stems, cotton waste, flocks, hemp, and other light material, which, by the aid of a solution of gutta-percha, or other chemical process, would form a solidifying mass so tough that it could not be knocked to pieces by shot, and so light that it would be only one half the specific gravity of water, and therefore unsinkable, however perforated by shot, and capable of carrying armament and naval equipment to the extent of nearly one-half the weight of its own displacement in tons. Such vessels of light draught accompanying fleets of war as tenders to line-of-battle ships, whence they might be manned and stored as occasion may require, would, I submit, form a useful auxiliary available for shore service, or attacking land batteries which deep-draught ships of the line cannot approach, and would be sunk if they could. I may observe that this idea was first broached by me two years since, as being applicable to the construction of vessels for carrying treasure and valuables, as diamonds and gold dust. They might be wrecked ashore, but the treasure would be recoverable.

LENOX'S IRON FLOATING DOCK.

MR. G. W. LENOX, of the Chain Cable and Anchor Works, Millwall, Poplar, under date Jan. 10th, 1859, writes:—

Thanking you for the prominent position you have given my "Floating Dock" in No. 2 of your New Series, I observe I have omitted, in my fear of occupying too much of your valuable space, to describe the essential, yet most simple point in its construction for management. As it is now before the public, for the benefit of any person or company willing to take it up, and after your remark that "The publication of Mr. Lenox's letter and illustration may tend to promote the adoption of the dock in many parts where it is much needed," I may be justified in the hope that, to make it better understood, you will again bear with me while I repair the omission in my first letter. The portion of the dock sunk is, as I stated, "double-sided." The bottom is also double. The space between the cases is divided into six air-tight compartments, each having a valve to admit and discharge water, and each a communication with the air or water-pump (as may be applied) which pump is worked by a steam-engine. I may name these compartments as two bow, two midship, and two stern-water chambers. Thus, when a vessel is to be docked, all six valves are opened, and, when the air-taps are turned on, the air escapes and the water enters, sinking the dock to the exact depth required to dock the ship; the air-taps are then turned off, the dock remains at that depth until the ship is floated in and secured. The air-pumps are then applied, when the water is forced out, and the dock rises, ship and all; the air-taps are again turned off, and the dock remains upon the water as long as required. The stern-gates are divided half-way horizontally, so that the upper half may be opened to admit light. By dividing the water-spaces into six or more parts, it will be seen that the trim of the dock can be regulated to a nicety by admitting more or less water on the starboard or larboard side, or into the head or stern-chambers. I trust you will think the whole affair simple and deserving this explanation.—Apologising for so soon troubling you again, I am, &c.,

GEO. W. LENOX.

MACHINERY FOR THE LADIES.—An ingeniously constructed arrangement of machinery has been invented by Mr. Tombs, of Islington, for manufacturing ruche and other trimmings for ladies' apparel, cap fronts, &c. The inventor employs a table on one end of which are two rollers. In a part of the table, in a framework, four fluted rollers are placed; at the other end is a drum working on an axis, and in a slot. The two pieces of ribbon to be made into a trimming, are taken up under guide rollers on the table between two other rollers which are affixed to the standards or framework of the four larger rollers, where jets of steam impinge on them for damping them. The top or narrow length of ribbon, and the lower or wider, are kept separate, and passed under upper and lower rollers. Having been damped, the ribbons are conducted through rollers placed in a framework or standard, and corrugated or fluted like goffering rollers, but in addition thereto, the under rollers are recessed or grooved in the middle, and the upper rollers are made in the corresponding part convex, or rounded, so as to take into the grooves or recesses, to press the ribbon into them, thus causing indentations for the reception of the gummed string. The ribbons then pass out and are conducted under guide rollers to a point where they meet with lengths of gummed string, which are brought up by any mechanical action under two rollers from a pot containing gum. As the ribbon passes from the creasing rollers to the drum, the string is carried forward simultaneously, and attaches itself to the ribbon on coming into contact. The two ribbons, having gummed strings attached, pass on to a drum on the periphery of which the smaller or upper ribbon is made to press on the lower ribbon and so to adhere. The drum is heated by gas for drying the material. The drum is worked by an endless band, which passes round it and takes on to a roller, which derives motion from the central goffering or creasing roller, and thus uniformity of motion is attained. It has also a reciprocating or excentric action given to it to prevent the overlapping of the ruche as it comes on. When taken off the drum the trimming is ready for use.

MISCELLANEOUS INTELLIGENCE.

IRON SHIPS.—Mr. J. Westwood, of the ship-building firm of Westwood and Baillie, Isle of Dogs, recently obtained provisional protection for several improvements in constructing iron ships. To ensure great stiffness with a comparative lightness, he proposed to use hollow beams, which he forms of vertical plates of metal, having solid liners between them, and angle iron bolted to their outside faces at their upper and lower edges. The lower angle irons continue beyond the ends of the beam proper, and are bent round and bolted to the opposite sides of the stiff angle iron constituting the ship's frames. In like manner the ends of the vertical plates are bolted to the ship's frames. For the purpose of ensuring a good firm joint in the plating of iron ships, he proposes when using a double thickness of plates, to arrange them so that they shall present three thicknesses at the point. Thus he takes two plates, and places them so that their edges will form a butt joint. Over this joint he laps a plate which will form with the under plate a double thickness of plating in one direction; and under this butt joint he lays another plate, which will form with the plate which it overlies a double thickness of plating in the opposite direction. Thus for each butt joint he has two overlapping plates (one at each side of the abutting plates,) and by passing bolts through the whole on either side of the butt joint he secures a firm fastening. In order to secure the exposed parts of the hull of ships of war against shot, he proposes to plate the upper part with thick plates (by preference of steel), formed with a rebate at their edges,, into which the adjacent plates will fit and produce a flush joint. This joint he covers with a strip of metal, and then by three lines of rivets fastens the whole firmly together. Mr. Westwood did not complete his patent.

IMPROVED GASELIERS.—Mr. J. Allardice, brass-founder, of Glasgow, and Mr. W. Miller, Manufacturer, Blantyre, have brought forward a method of constructing pendant gaseliers (either fixed, like crystal, or sliding, like bronze gaseliers) with a sliding tube bearing additional burners, and so that the latter may be brought considerably below the level of the main burners, when desired—for reading, say. This sliding tube is never detached, but is pushed up inside the central tube when out of use. In crystal gaseliers the burners of the sliding tube may be concealed in the crystal ornament when out of use, the burner branches folding up. These branches may be so contrived as to turn the gas on and off as they are unfolded or folded, thus dispensing with stop-cocks.

THE PRODUCTION OF SILK.—Dr. Tarlirana of Milan, who has just set out on his journey to Central Asia—undertaken partly for scientific, and partly for industrial purposes—is at this moment at Berlin, in order to solicit the advice and recommendations of Baron Humboldt, Karl Ritter, and Prof. Dove. The expedition is to extend as far as the Chinese frontier, with the object of there investigating the production of silk.

PATRIDGE'S APPARATUS FOR SUPERHEATING STEAM.—The following letter has been received at the Dockyard, Woolwich, from the chief engineer of the steamship Prince Alfred, relative to the working of the Admiralty apparatus fitted on board that vessel for superheating the whole of the steam required for working the machinery:—

Cape of Good Hope, Nov. 9.

"Dear Sir,—I am glad to inform you that your patent apparatus has given me great satisfaction, and I have had no trouble in the tropics with the temperature of the steam. There have not been more than 10 degrees difference since we left Milford, which happened when the tubes were nearly full of soot. We had them swept, and the steam came to the old mark on the gauge—namely, 330 degrees, which is about the mean temperature. The highest temperature we have ever had is 350 degrees, which occurred on the 2nd of November, the thermometer at 70 degrees. We have had the thermometer up to 120 degrees in the tropics, on

Digitized by Google

which occasion the steam was at 325 degrees, the tubes being clean at the time. We have been 700 hours under steam and have had no trouble with the cylinders, trunks, stuffing boxes, &c. The same stuffing that we left London with is in now, and is in good condition. We save from 25 to 30 per cent. in fuel, and as coals are very expensive in the colonies the economy is important, and I am of opinion the apparatus will take well.

"JOS. LOWES.

"To D. Patridge, Esq.

PUMPING SOVEREIGNS.—The 20-horse power engine at the Mint has a double duty to perform; it pumps at once water and sovereigns! This engine is on the high and low pressure principle, and was invented some ten years since by the Messrs. Rennie. As regards the water-pumping arrangements, it may be said that a spur pinion on the fly wheel shaft gives motion to a wheel attached to a three-throw crank shaft, which again works the pumps beneath. The well is 420 feet in depth, and the pumps, of 9 inches diameter, throw water into a large cistern fifty feet from the ground; thence the water flows to every part of the establishment. Pumping sovereigns, however, is a different thing. In order to accomplish this, a very large double acting air pump—designed a few years since by a subordinate officer of the Mint, who was not rewarded for his pains—is placed below the beam, and worked by a rod dependent thereon. This pump exhausts (in both the up and down strokes) a tube 220 feet in length, connected with a vacuum chamber near the coining press room. Necessarily the vacuum chamber—fifty feet in length, and three feet six in diameter—is exhausted, too, and on the upper part of this stands eight pneumatic pumps ingeniously fitted with valves, levers, springs, and other fitments, and attached by means of rods to the hollow upright shafts of the presses themselves. The pumps of the presses are forced down by the intermittent action of the atmosphere upon the pistons, packed with leather, with which they are supplied, and carry with them the screws of the presses themselves. Boys feed the presses with gold or silver blanks, and have complete command over them and the pumps. Motion is given to both at the rate of from 60 to 70 per minute, and the dies deliver into trays provided for the purpose streams of gold coins at the same speed, and which have a most tempting appearance. Thus are sovereigns *pumped* into existence. Some day we may explain this operation more fully.

HARRISON'S ELECTRIC LIGHT APPARATUS.—Mr. C. Weightman Harrison, of Woolwich, who has had much experience in the production of the electric light, has patented the following improvements. They relate to the use of mercury or other fluid or semi-fluid as an electrode in obtaining light by electricity, and consists, 1, in the employment within the lamp of a burner fed with a supply of the electrode, so that it shall remain full or nearly so during waste or consumption by the light. 2, In controlling the supply of fluid electrodes by a tap, &c., worked by electric action. 3, In forming a fluid positive compound electrode by dividing the stream so that a number of separate lights may be produced from it. 4, in maintaining by self-acting means a constant degree of separation between the point where the stream of one electrode breaks, and the reservoir of a second electrode into which the stream falls or forms contact. The patentee accomplishes this by connecting the reservoir of the second electrode to a float which is placed on the first electrode contained in another reservoir, from whence the stream issues, whereby as the float descends, the second reservoir is advanced in exact proportion to the length which the stream is diminished by reduced pressure. He also effects the same object by causing the waste or condensed fluid forming a descending stream electrode, to elevate the lower electrode or reservoir; this may be done by placing it on a float under which such waste fluid is allowed to collect. 5, In forming the reservoirs for holding fluid electrodes of a combination of lamp black or other form of carbon and silica, or of lamp black and china clay, rotten stone, &c. 6, In preventing the condensation of vapours upon the glass or case of electric lamps by a stream of liquid or air being made to flow over or upon the interior surface of the glass or case. Also by partly or wholly filling the glass or case with water, alcohol, bisulphuret of carbon, &c., and in causing it to circulate around the light, or to pass away through apparatus by which it may be filtered, and then returned to the lamp again by a pump, &c., worked by electric action. 7, in preventing the rise of vapours from the waste fluid of electrodes by the introduction of a stratum of water or other liquid into the waste pipe or reservoir.

CURRENT EVENTS IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

(COMPILED BY OUR OWN CORRESPONDENT.)

In re Wm. Riley and Son, ironmasters, Wolverhampton—A Trade Civil War between masters and men amongst the Coventry weavers, the flint-glass makers, the brick-makers, and the shoemakers of Stafford—Introduction of machinery to that town—Remarks on Trades' Struggles—The proposed great bridge over the Trent at Burton—Hollow Hurdles—Shocking death of an engine boy.

Mr. W. Riley, who failed for so large a sum during the late crisis, and whose affairs have been in the Birmingham Bankruptcy Court as "W. Riley & Son, Millfields, Wolverhampton," has at length succeeded in passing his last examination.

A trade civil war appears to be threatened between the masters and their men in two or three prominent branches of the manufactures of the West Midlands. The conflict between the silk weavers and their employers at Coventry terminated a short time ago in success to the former.—War to the knife is now waging between the glass-makers and their men, the former determining by a mutual combination to rid themselves of the dictation of the workmen's trades union, and the latter determining not to yield. As a consequence there is now a lock-out.—The Operative Brickmakers' Union has been felt by the masters to be obnoxious for some time past. They have just taken steps with the view of stopping its further encroachments.—Generally in the North the colliers have come off tolerably well in the struggle with their employers. It was not so, however, in South Staffordshire. Feeling this, their fuglemen are again summoning them to a renewal of the strife. At Wigan the colliers are meeting a thousand strong, demanding a rise of wages of 2d. in the shilling.—The notable shoemakers of Stafford are raising their backs, and assuming amazing contortions upon the faintest whisper of the introduction of machinery into their quiet little assize town. The employers have been intimidated by these tricks for some time past, but a familiarity with the "danger" has bred contempt for it. Accordingly they have smuggled some machinery into the town, and it will shortly be at work. With the exception of the last-mentioned case, we regard these contests as proceeding from a sense of rights and privileges entertained by the men as attaching to their grade, and are not disposed to look upon them with hopeless regret. To us they indicate a kind of self-respect which the progress of temperance and education will make really valuable to themselves and the community. For the present, all know that the working masses are not able to profitably discuss the important relative proportions of the rights of labour and the rights of capital. And we are by no means prepared to say that capitalists are on their side much more distinguished. But the schoolmaster is abroad.

Over the Trent at Burton there is a bridge built originally for pack-horses, and which is now in a very dangerous state. Its owner, the Marquis of Anglesea, who possesses the greater part of Burton, and whose property there is rapidly increasing in value, proposes to apply to Parliament for powers to erect a new bridge, and to borrow for the work £30,000 on mortgage, the original expense to be borne jointly by himself and the counties respectively of Stafford and Derby in which the bridge is situated, the counties to keep the bridge in repair. The magistrates of Derby have instructed their clerks of the peace to oppose the bill in Parliament, as have also the magistrates of Staffordshire, by one of whom it was stated in Quarter Sessions that the proposed bridge would cost £62,400.

The Blyth and Tyne Railway is soon to be extended to Warkmouth-on-the-Cocquet; and in connection with it, it is proposed to construct a branch to Tynemouth. As large a quantity of coal as 4,000 tons a day is being carried over this line.

Coals have begun to be shipped from Jarrow Docks. The opening of that port for such a purpose is regarded as likely to tend to a considerable increase in the coal trade of the north.

One of the many children employed in South Staffordshire in the serious and important duty of working colliery engines was oiling the machinery of his engine whilst it was in motion on Tuesday at Darlaston, and slipping, fell amongst the machinery and was killed instantly. The deceased was fourteen years of age!

NOTES FROM THE EASTERN DISTRICTS.

(FROM OUR OWN CORRESPONDENT.)

Flax Works at Gainsborough—Norfolk County Surveyorship: Estimates and Expenditure—Gas at Boston and Louth—Bedford and Cambridge Railway—Wisbeach and the River Nene—Water supply of Chelmsford—Steam Engine for the Norfolk Lunatic Asylum.

FLAX works are in progress at Gainsborough.—On Friday the Norfolk magistrates continued some time in high debate—the principal subject of their deliberations being an excess on the estimates delivered by Mr. John Brown, county surveyor, with regard to extensive works which have been for a long time in course of execution at the county lunatic asylum. There were complaints expressed on the matter at a previous session, and Mr. Brown was directed to deliver in a statement on the subject. The "visiting justices" of the asylum do not consider that Mr. Brown has altogether explained to their complete satisfaction the excess which has occurred on the estimates; but it appears to be granted on all sides that the works have been well executed, and that Mr. Brown has paid close attention to them. The magistrates on Friday appointed a committee to consider the duties and emoluments of their surveyor, and resolved that Mr. Brown should be re-appointed at Easter for six months only, and that at the expiration of that period the office should be considered open. The appointment will probably be placed in a better position for the future. Mr. Brown's remuneration has been considered inadequate from the first.—At Boston the Gas Company propose to add to their works a large gas-holder, exhauster, &c. Plans and estimates are to be delivered by Mr. R. P. Spice. At Louth the Gas Company have made an additional charge of 5s. per annum for each public lamp.—The Cambridge town council have been discussing a project for a new railway between that town and Bedford. The parliamentary committee recommended, and the council endorsed the opinion, that a new passenger station would be necessary at Cambridge, the present station of the Eastern Counties Company being inconvenient, and far too distant from the town. The committee generally approved of the undertaking, which the council resolved to support.—The Wisbeach town council—after all said against country "corporations," it cannot be denied that their proceedings frequently afford the most reliable insight into what is passing in their respective neighbourhoods—have been further considering the state of the river Nene, and the works of the Nene Valley Drainage and Improvement Commissioners; and, after a protracted discussion, have resolved to invite Mr. T. Page, engineer, of Middle Scotland-yard, to confer with them upon the state of the river. The council have also resolved to take proceedings against the commissioners with a view to secure the removal of the dams placed in the river, which the Wisbeach public consider detrimental to their trade and port—if they are not taken away at the expiration of a certain period specified in a notice recently served. The commissioners, if we may judge from their recent proceedings, are not likely to concede the claims of the council very readily.—At Chelmsford, the town surveyor, Mr. F. Chancellor, has been reporting to the Local Board of Health upon the water supply of the place After mature consideration, he recommends as a source of supply, an artificial lake formed at the time the railway (Eastern Counties) was constructed. It is described as abounding in springs, while the water is of tolerable quality. Mr. Chancellor suggests that the water should be conducted in iron conduit pipes to a filtering tank, to be constructed in the board of health yard. He suggests Ransome's filtering slabs as the filtering medium, remarking that, although more expensive at first, they are easily cleansed, a circumstance which leads to a large annual saving. Mr. Chancellor enters into minute details, and states that he proposes the erection of a water tower eighty feet in height. The Local Board of Health have complimented Mr. Chancellor on the ability of his report, which is to be further considered after the levels of the lake and of the river (Chelmer) have been taken, when the water in the river has been tested, and when other inquiries have been made.—The improvements and alterations at the Norfolk Lunatic Asylum, to which reference has just been made, include a six-horse power steam-engine, supplied by a ten-horse power boiler, which is also to furnish steam for washing, drying, cooking, heating apartments, &c.; Mr. W. Naylor, C.E., has been concerned in the superintendence.

NOTES FROM THE SOUTH WEST.

Exeter and Yeovil Railway—Baths and Wash-houses at Bristol—A Beacon for Dartmouth—Progress of the Public Drinking Fountain Movement—Bills in Parliament—Bristol Shipping—The Price of Gas—Improvement of the Port of Bristol—Smoke Consumption at Southampton—Steam Engine for the Hampshire Lunatic Asylum—Larking on a Railway.

THE works on the Exeter and Yeovil Railway are progressing rapidly, and the line is expected to be opened for traffic in July or August. A large tunnel at Honiton, to which reference is made as the "governing work of the line," was cut through about three weeks since. This tunnel is about a mile in length. Another short tunnel at Lion's Holt will also be soon cut through.—It is stated that the town council of Bristol loses £150 per annum by its baths and wash-houses; and it has been suggested that they should be "farmed out." Mr. Herapath expressed an opinion, on this suggestion being made, that the baths were a great boon to the public, there having been as many as 26,000 bathers in a year. The town clerk stated that there had been a decrease. Engineers were great bathers, and the decrease arose in consequence of a large factory in the neighbourhood of the baths not having been in full operation during the year. The council has not resolved to make any change on the subject.—An influential meeting has been held at Dartmouth with the view of memorializing the Admiralty, or Board of Trade, to erect a beacon at the eastern entrance of the harbour. A unanimous feeling was manifested on the subject. Captain Shtringham, R.N., Admiralty Surveyor, was present, and is reported to have observed that Dartmouth would be the best harbour on the coast both for vessels of the Royal Navy and the mercantile marine, if the proposed beacon were erected.—Mr. R. Lane, a member of the Bristol town council, has offered to give £100 towards the erection of a drinking fountain opposite the Fine Arts Academy, near the Victoria Rooms, Queen's-road, in that town. At Plymouth the local press is also directing attention to the subject.—At Glasgow the Water Commissioners are engaged in erecting two public fountains in each of the sixteen wards of that city.—Among the private bills to be promoted in the forthcoming session, are the following:—Dartmouth and Torbay Railway, Somerset Central Railway, Falmouth Docks and Harbour, Bridport Railway, Tavistock Markets and Improvement, Kingsbridge and South Devon Railway.—The number of vessels entering Bristol from foreign ports in 1858 was 846. Of these 452 were British, and 394 foreign vessels of an aggregate tonnage of 199,119 tons.—The Somerset county magistrates are dissatisfied with the price paid for gas at the county gaol at Taunton, viz., 5s. 6d. per 1000 cubic feet. The gas company offer to make a reduction of 9d. per 1000; this does not satisfy the justices, and the company declining to

Digitized by Google

make any further abatement, they threaten to take the matter into their own hands. At the county sessions a lengthened discussion has taken place on the matter. At the previous sessions, the visiting justices were requested to ascertain whether it would be advisable to have gas works erected on the gaol premises, and whether it would be beneficial to the county. It appeared that the probable cost of the works would be about £600, the whole of which, it is estimated, would be saved in the course of four years. The justices, therefore, reported that they considered that the county money might be properly applied to the purpose, while the supply of gas would be superior. A question was asked whether the erection of a gasometer would not be prejudicial to the health of the governor and the inmates of the gaol; and it was replied that at Pentonville this was not found to be the case. Reports presented to the visiting justices by Mr. Williams (of Bath), Messrs. Barrett, Exall, and Andrews, and Mr. Cockey (of Frome), exhibited a considerable agreement. The effect of them was that gas could be supplied for about 3s. per 1000. It was proposed and seconded that £600 should be granted to the justices, and that they should be authorised to enter into a contract for the necessary works; and it was stated that the surgeon at the gaol had expressed no objection to the erection of a gasometer on the premises. One justice even observed that the medical man had stated that it would be an advantage rather than otherwise—a remark which excited some laughter. The proposition thus far proceeded swimmingly, but here it encountered opposition from Mr. W. Moody, who expressed his objection to such a "fearful experiment" as the erection of a gasometer within the immediate precincts of the gaol. Mr. Moody stated that to the erection of a gasometer between Blackfriars Bridge and the Temple, the residents of the district had objected; and in the case of a gasometer close to a farm of his at Glastonbury, the neighbours stated that once a week there was such a stench as they could scarcely endure. He considered that experiments to conduct gas-works without smell had failed. Another magistrate expressed his doubts on the economical aspect of the question, which was postponed for further consideration to the next sessions.——The Bristol town council has been discussing the accommodation afforded at that port. The docks' committee reported that they had received great complaints of the want of shed accommodation on the public quays and wharves, and that they felt that the provision hitherto made in this respect was altogether inadequate to the requirements of the port. A great difficulty in the way of supplying the defect arises from the fact of the wharves being held by the Society of Merchant Venturers under a lease which will not expire until December, 1863. The result of this is, that the society cannot be expected to make a large outlay on property held on so short a tenure, while the town council would not be justified in spending the public money on property not in their possession. The docks' committee recently appointed a deputation to wait on the standing committee of the Society of Merchant Venturers, but that worshipful body required a resolution of the council before they would treat for the surrender of the lease. The requisite resolution has been passed by the council, which was informed by one of its members, Mr. R. P. King, that an important document had been received by the docks' committee with reference to dock and river improvements. The cost of carrying out the necessary improvements somewhat exceeded the anticipated estimates; but vessels of much larger size would be enabled to enter the port if the improvements were carried out.——At Southampton a smoke prevention apparatus (Mr. O'Regan's) has been applied to the furnaces in connection with the steam dyeing works of Messrs. Carter and Son, East Street, it is said, with considerable success.——A steam engine of six-horse power has been erected in the Hampshire county lunatic asylum by Messrs. Easton and Amos, for the purpose of pumping the water-supply into tanks.——A sad result of "larking" on a railway occurred on Friday on the Bristol and Exeter line. Five lads who were about to join one of Her Majesty's ships at Plymouth, left Bristol by the down express. One of them persisted in sitting on the edge of one of the windows, with his head and body outside. Near Taunton his head struck one of the bridges, and he was killed instantly.

METAL AND COAL TRADES, &c.

(FROM OUR OWN CORRESPONDENT.)

Quarterly Meeting of the Iron Trade, Cheering Prospects---The Coal Trade of South Staffordshire---Colliers' Movement---The Iron Trade of South Durham and North Yorkshire---Stockton and Darlington Railway---New Furnaces---Staple Trade of South Wales---The Iron of Ebbw Vale---The Report of the Government Inspectors---Birmingham Business---Railway Carriage and Building Trade---The Metal Market---Tin and Copper---Advance in Prices---Iron Exports from Liverpool, and Average Prices for the last Two Years.

The usual Quarterly Meetings of the Iron Trade were held in Wolverhampton on Wednesday, in Birmingham on Thursday, and will be continued to-day in Birmingham, and to-morrow (Saturday) in Dudley. The reports of the various members of the Association showed that the prospects of the Trade are of a cheering character. Prices are looking up. Pig iron has an upward tendency, and some members of the Trade consider that no difficulty will be found in obtaining 10s. per ton extra for merchant iron of first-rate quality; in proof of this we may mention that Mr. Smith, Lord Ward's principal agent, has issued circulars declaring an advance of 10s. per ton upon finished iron. It should be borne in mind that this notice of an advance only raises the prices of iron to their recent standard. The market price of bars originally stood at £8, but 10s. per ton was taken off some time ago upon export orders, and no doubt many parties effected sales at £7 10s. for home deliveries; but now, as symptoms of prosperity have become so manifest, and pig iron firmer, £8 for bars of good quality is alleged to be a fair and legitimate price. One large house in South Staffordshire has received a foreign order for the supply of £800,000 worth of large pipes or tubes. The trade as a whole did not resolve to follow the course which Lord Ward's agent has taken, but prudently resolved to adopt the recommendation of the preliminary meeting, and keep prices at last quarter's level. The coal trade of South Staffordshire is reported as tolerably brisk. The colliers there have began a movement by which they contemplate an appeal to their employers for an advance of 6d. a-day upon their present wages. If their demand should not be conceded, they have announced that they will strike for a return to the 1s. a-day that was taken from them at one sweep before the late strike.

The iron trade in South Durham and North Yorkshire shows, it is stated, indications of improvement. Of 65 furnaces 58 are in blast, and only seven out. The receipts of the Stockton and Darlington Railway are getting back to their former high level. Several new furnaces are also in course of construction.

Considerable satisfaction is felt by persons interested in the staple trades of South Wales, from the reflection that so few houses, comparatively, have been severely affected by the commercial disasters of the past year. The reports from that part of the kingdom speak of an improvement in the trade having been commenced which will become more decided as Spring advances. The large iron works at Ebbw Vale, Blaina, Blaenavon and Nant-y-Glo, are working full time. The Welshmen trust that to them will be awarded the laurels in the competition with the men of the North, on the comparative merits of the coal of those two districts for the evaporating of steam. They therefore wait confidently for the appearance of the report of Mr. Taplin, of Woolwich, and Mr. Lynn, of Portsmouth, the Government Inspectors who conducted the investigation.

In Birmingham, business generally is improving. The workshops are moderately well employed. In the railway carriage and waggon building trade, which now employs a large number of hands in the town and district, business during the past year was good, and present prospects are very satisfactory.

No material change has occurred in the general aspect of trade in Wolverhampton during the past week. A few orders have been received from the travellers who have just commenced their journeys, but not in such numbers as to afford any index to the position which trade is likely to assume during the current quarter.

The metal market is very unsettled. Tin, which has for the few past weeks shown symptoms of an upward tendency, was on Saturday last advanced 3s. per cwt., making common blocks 123s. 6d. per cwt.; refined ditto, 133s. 6d. per cwt.

An advance of a halfpenny per pound took place in the price of this metal on Tuesday, making tough cake and tile £112 10s., and best selected £115 10s. per ton.

By the last annual trade circular of Mr. F. Robinson, of Liverpool, we find that there was exported from Liverpool, in the year 1857, 287,408 tons of iron, which was distributed as follows:---Bars, 132,563; rods, 13,904; hoops, 22,095; sheets, 29,335; plates, 11,738; pigs, 16,267; rails, 61,506. In the year 1858:---Bars, 130,030; rods, 15,974; hoops, 23,398; sheets, 24,592; plates, 8,807; pigs, 28,872; rails, 33,945. Total, 265,618. In 1857 the average price of merchant bars was £7 18s. 9d.; in 1858, £6 12s. 5d. The average price of Staffordshire rails was in the former year £8 4s. 9d.; last year, £7 7s. 9d.

Respecting the Scotch iron trade in the past two years, we gather from the circular of Mr. F. Robinson, of Liverpool, referred to elsewhere, that in the year 1857, the stocks in Scotland amounted to 100,000; in 1858, 340,000 tons; that the furnaces in blast in the former year was 123; those in 1858, 131; that the make of malleable iron in Scotland was 100,000 tons in 1857, and 90,000 last year; also that the average price of bars in Glasgow for the year 1857 was £8 10s.; in 1858, £7 10s. Mr. Robinson also gives the following as the average price of Scotch pigs, No. 1, G. M. B., in 1857, as £4; in 1858, £3 1s. 4d.

2931. J. J. Welch, of Cheapside. Improvements in the manufacture of neckties, scarfs, or cravats.

Dated December 23, 1858.

2933. J. Ronald, of Liverpool, Merchant. Improvements in, and machinery for, the manufacture of hard-topped and soft laid twine, mill banding strands, for ropes and other purposes, and cordage generally from hemp, flax, cotton, and other like fibrous material.

2935. J. Broom, of Glasgow, Iron Manufacturer. Improvements in the manufacture of steel.

2937. A. Barclay, of Kilmarnock, Engineer. Improvements in obtaining and distributing or applying electricity and magnetism, and in obtaining motive power therefrom.

Dated December 24, 1858.

2939. J. T. P. Newbon and T. Smith, of Fenchurch-st., Naval Architects, and J. Brown, of Follit-st., Engineer. Improvements in machinery or apparatus for raising and lowering, or otherwise moving heavy weights.

2941. J. W. Child, of Halifax, Engineer. Improvements in the manufacture of fabrics adapted to be used for curtains, coverings of furniture, table covers, and such like uses.

2943. L. D. Owen, of Tottenham-court-road, Engineer. Improvements in manufacturing horse shoe nails. A communication.

2945. D. Edleston, of Halifax, Dyer. Improvements in preparing and finishing textile fabrics, and in the means or apparatus employed therein.

2947. E. Humphrys, of Deptford. Improvements in brazing metal tubes in tube plates and other metal surfaces to each other.

2949. J. Little, of Glasgow, Ironmonger. Improvements in lamps.

2951. R. L. Giandenati, of St. Paul's Churchyard, Merchant. Improvements in ornamenting leather cloth.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated January 3, 1859.

26. M. A. F. Meanons, of Paris. Certain improvements in steam generators.—A communication.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1955. G. Weedon and D. W. Rice. Knife cleaning machine.
1963. J. Oxley. Baths.
1975. J. Stoneman. Fibrous materials.
1984. W. Hobbs. Ordnance and projectiles.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this magazine from official copies supplied by the Government, and are therefore the property of the proprietors of the Magazine. Other papers are hereby warned not to produce them without acknowledgment.

STEAM ENGINES, &c., 1017, 1018, 1063.

BOILERS AND THEIR FURNACES, 1026, 1033.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1014, 1020, 1030, 1036, 1072.

SHIPS AND BOATS, including their fittings, 1031, 1036, 1044, 1066, 1077.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1040.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1048, 1064, 1073.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1015, 1016, 1021, 1034, 1045, 1046, 1047, 1051, 1052, 1058, 1059, 1060, 1070, 1075.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 1024, 1067.

LIGHTING, HEATING, AND VENTILATING, 1026, 1028, 1029.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1023, 1025, 1036, 1039, 1053, 1054, 1065, 1074.

METALS, including apparatus for their manufacture, 1019, 1043, 1049, 1061.

CHEMISTRY AND PHOTOGRAPHY, 1015, 1051.

ELECTRICAL APPARATUS. *None.*

WARFARE. *None.*

LETTER PRESS PRINTING &c., 1050, 1056, 1060.

MISCELLANEOUS, 1015, 1017, 1019, 1022, 1024, 1027, 1028, 1032, 1035, 1036, 1037, 1038, 1041, 1044, 1055, 1057, 1062, 1068, 1069, 1070, 1071, 1073, 1076.

1014. W. CLARK. *Improvements in bits for horses bridles.* (A communication.) Dated May 6, 1858.

The arrangement consists of an ordinary bit, to which the patentee adds a nose band carrying two small steel pallets which press on the nostrils of the horse to close or stop them. The nose band is furnished throughout the inner surface with small knives or teeth, which aid in making the horse obey. The movement of this nose band is produced by a supplementary rein. *Patent completed.*

1015. J. WRIGHT. *Improvements in treating madder for printing and dyeing, and also in the substances and processes used in printing and dyeing with the same.* (A communication.) Dated May 6, 1858.

The patentee mixes madder in the raw state with water, or bran water,—1 by weight of madder to 5 of water. After a little time he puts the mass into a coarse calico bag and presses it in an ordinary press, receiving the expressed liquor into a vessel, which, after standing, forms a jelly, and afterwards separates into a solid and liquid. He then washes thoroughly the resulting colouring with clear water, and strains it off. This, upon being reduced to a proper consistency with gum or mucilage, as usual, is ready to dye or print with. Or the jelly may be treated with dilute sulphuric acid, or any vegetable substance containing an acid, or even with common salt. Afterwards it must be thoroughly washed so as to remove all trace of the acid, then strained and pressed so as to get rid of the water. Upon being reduced to the proper consistency, as before, it is ready to dye or print with. Or the water may be all evaporated and a dry powder formed. He takes the refuse madder left from the last operation and treats it in a similar manner,—that is, obtaining a jelly extract. Finally, he mixes the refuse madder remaining after the the two operations with warm water, allows it to stand, then boils it; a precipitate is thus formed, which, after running off the clear supernatent water, he treats with caustic potash, then washes well and strains. He precipitates the colouring matter from the mass of water by sulphuric acid, after boiling. The residuum or precipitate thus obtained may be added to the products of colouring matter obtained as above described. The invention includes other details. *Patent completed.*

1016. H. JACKSON. *Improvements in machinery for dressing and cleaning flax, hemp, and other fibrous substances requiring like treatment.* Dated May 6, 1858.

Here a cylindrical drum is used, having elastic projecting blades or beaters on its circumference, parallel with its axis. This drum revolves within a fixed case closed at the ends and back. In front of the case is an opening, through which the fibrous material (which is held by a holder) is introduced, and as the blades rotate they strike the fibres; the air also brought round by the blades has a tendency to drive the fibre away. Below the opening there is another some distance down, having at the lower part an adjustable guard, to deflect off the air. In front of it is a grid or frame of bars through which the air can get away, but which prevents the fibrous substances escaping. *Patent completed.*

1017. W. WALLIS, W. LANGFORD, and J. SLACK. *Improvements in pressure guages.* Dated May 6, 1858.

In connexion with a boiler or other vessel (sustaining pressure) is a metal cup with a flange at its upper edge. On this flange is a disc of thin sheet brass, or vulcanised India-rubber, &c., and over this is a second disc of tempered steel, in which a number of straight slits are made proceeding radially from the centre, and each equal in length to half the internal diameter of the cup on which the discs are laid. The discs are kept in their places on the flange of the cup by a metal ring, which rests on their edges, and is fastened by screw bolts. As the pressure in the cup increases so will the sections of the slit steel plate be deflected more and more from their natural position. To complete the instrument it is necessary to connect with one of the sections of the steel plate apparatus for indicating the amount of its motion,—say a rod giving motion to a toothed quadrant, which drives a pinion, on the axis of which a pointer moving over a dial. *Patent completed.*

1018. J. and J. G. BUNNETT. *Improvements in steam-engines.* Dated May 7, 1858.

This relates to a former patent, dated June 14, 1838, and consists in the employment of a solid annular piston rod working round a circular guide, instead of on a circular axis, as heretofore; also in placing the steam ways in the centre part of the engine, and working them by a single slide, which renders the two slide valves with their connecting gear, formerly employed, unnecessary, and enables the whole of the internal working parts to be got at by taking off one side covering plate, without disturbing any other parts of the engine. *Patent completed.*

1019. C. J. CARR. *Improvements in forge and other hammers.* Dated May 7, 1858.

This invention is not described apart from the inventor's drawings. *Patent completed.*

1020. J. CASTLE. *Certain improvements in breaks used for retarding the motion of carriages on ordinary roads.* Dated May 7, 1858.

This consists, 1, Of a rod jointed so as to permit it to revolve in its whole length when turned at one end, notwithstanding that certain parts be curved longitudinally when applied to the working of a brake for retarding the motion of wheels of carriages on ordinary roads. 2, Of a traversing nut, jointed to the lever of a brake, and arranged to work the same by the revolving of a screw on which it is placed. 3, Of two screws or threads and traversing nuts on the same rod, arranged to work the levers of a brake in opposite directions at the same time. 4, Of an arrangement for working a brake by handles from one or both sides of a vehicle. *Patent completed.*

1021. R. OPENSHAW. *Improvements in machinery for plating down or folding and measuring fabrics.* Dated May 7, 1858.

This invention is not described apart from the inventor's drawings. *Patent completed.*

1022. W. DUFF and J. GILCHRIST. *Improvements in apparatus for measuring water and other fluids, also capable of being used as a motive power.* Dated May 7, 1858.

The inventors use an ordinary direct acting engine so far as the framing, cranks, crank shaft, and excentrics are concerned, for working two slide valves in the ordinary way; but instead of the cylinder and piston they place a square chamber with inlet and outlet passages securely fastened midway in this chamber; they fix a sheet of elastic substance (say india rubber), to which they connect a rod through a stuffing box to the cranks above mentioned. The valves being adjusted, and the water turned on from the supply, it will flow into one of the chambers connected with the open valve; its pressure will then expand the elastic substance until it fills the chamber, the contents of which being known, each stroke of the piston acting upon the cranks will give motion to the shaft to which a worm and wheel are connected that acts on a common index or indicator. This index will show the quantity of fluid which has passed through the apparatus. *Patent abandoned.*

1023. J. M. DUVARD. *An improved bed-room vase.* Dated May 7, 1858.

The patentee describes a vase or utensil having an upper and lower chamber fitting closely into each other. The upper chamber is funnel-shaped, and pierced with a hole leading to the lower chamber, so as to convey to it the liquids or contents deposited in the upper chamber. He places in the upper chamber a ball having a cord passing through a hole to the exterior, to prevent any effluvia escaping through the said hole. He puts knots on the cord, which effectually stops the orifice. The ball acts as a valve, falling by gravity into the hole of the upper chamber, and preventing any effluvia arising. *Patent completed.*

1024. J. J. FIELD. *Improvements in evaporating or in extracting moisture from liquids, and from substances in a liquid state, and in apparatus to be employed therein.* Dated May 7, 1858.

This invention consists in the employment, for the evaporation, of dry gases or vapours of such nature as to prevent the oxidation of the matters acted upon (where it is desirable to prevent oxidation therein). The patentee drives or forces such dried vapours or gases through the liquids or substances, divided in numerous small streams, sheets, or jets; or he passes them over the liquid or substance to be acted upon. He then causes the moist vapours or gases to pass through or over chloride of calcium or other agent having a great affinity for water, whereby they are deprived of their moisture, and rendered fit to be used as before; or they may be passed into a mechanical drying chamber. This invention also consists in sub-dividing the liquids to be deprived of moisture into numerous small streams, sheets, or jets, so as to expose a larger surface to the action of the agent employed to deprive them of their moisture. The apparatus consists of a pipe leading from the drying chamber into a reservoir having one of its sides perforated with small holes or slits, through which the dried gases or vapours pass into a chamber wherein the liquid to be operated upon is presented to their action. The gases or vapours then pass through another series of perforations into the chemical or mechanical drying chamber, whence they are conducted to be used over again. After the fluids fall in the liquid chamber, he raises them by pump or otherwise, to be again divided into streams, and so continues. The process is particularly applicable to the obtaining of pharmaceutical extracts, and to the evaporation of sugar, gelatine, &c. *Patent completed.*

1025. A. NEILSON. *Improvements in the manufacture of boots, shoes, and other coverings for the feet.* Dated May 7, 1858.

This invention is described at p. 31 of last Number. *Patent abandoned.*

1026. W. E. NEWTON. *Improvements in the construction of fire-grates for furnaces, stoves, and other fire-places.* (A communication.) Dated May 7, 1858.

This invention consists in the employment, as a fire-grate for furnaces, stoves, &c., of a series of flexible bars, composed of chains, metal rope, or linked rods, arranged side by side, and attached by their ends at the back and front or side of the fire-box or furnace, with sufficient slackness to permit them to swing or be shaken. *Patent completed.*

1027. G. B. COGGAN. *A new portable apparatus to be called a "Stereoscopia," for exhibiting stereoscopic pictures.* Dated May 7, 1858.

This invention consists of a square platform, mounted on wheels, having fixed to it a box about 2½ft. square and 7ft. high, with a glass top. At the front and back of the box the inventor inserts sets of lenses, and in the interior places a cylinder of wood from side to side, having an axis at each end, upon one of which he places a winch handle for changing the subjects. In the lower portion of this apparatus he conveys photographic apparatus. *Patent abandoned.*

1028. C. BOTHEN, jun. and N. F. TAYLOR. *Improvements in means and apparatus employed in measuring and in regulating the flow of gas and other fluids.* Dated May 7, 1858.

This invention consists in causing the gas to be measured by dry meters having sliding valves to pass first into the valve chamber, so as to press on the outer surface thereof, to keep the valves to their seats. The outer rubbing surfaces of the valves, or those parts in contact with the outer edges of the seat, are made wide that at each extreme motion one of the rubbing surfaces of the valve may be overhanging its seat; the valve seats are thus kept clear. The improvements relating to the moveable partitions or diaphragms consist, when forming them of several plates of metal united by leather or other flexible material, in employing a large central plate and narrow plates round the edge, the centre plate being united to those around the edge of it, as also these edge plates to the case by prepared leather; and to ensure the correct relation to or operation of these plates, they are connected at suitable places by connecting links. *Patent abandoned.*

1029. R. BEST. *An improvement or improvements in illumination.* Dated May 7, 1858.

This invention consists in combining two or more burners projecting flat or sheet-like flames in a nearly horizontal plane in the interior of a shade or dome, the burners being situated excentrically to the axis of the shade or dome, and being so situated with respect to the shade or dome that the flames converge towards its middle or axis. *Patent completed.*

1030. T. and D. BROWN. *New or improved machinery for filing or smoothing the ends of fish-plates, rails, wrought-iron railway chairs, and other articles made by sawing bars transversely.* Dated May 7, 1858.

This invention relates to machinery consisting essentially of a rotating roll or cutter, or rotating rolls or cutters, having grooves of a form suitable to act upon the bar or plate to be filed or smoothed, the grooves being cut similar to the way in which files are cut, provided with cutters inserted therein. *Patent completed.*

1031. D. STOTHARD, J. JONES, D. JONAS, and B. W. JONAS. *An improved ship's block.* Dated May 7, 1858.

This invention consists of an outer sheave or block furnished with a channel, in which pulleys are so arranged as to admit of the rope impinging upon the peripheries so as to increase or diminish the space between the same, through the medium of a concentric slot bearing in which

Digitized by Google

one of the lesser wheels revolve, the larger or fixed wheel moving from a common centre as heretofore. *Patent abandoned.*

1032. W. CLARK. *Improvements in apparatus for sharpening saws.* (A communication.) Dated May 7, 1858.

This invention relates to a machine for sharpening all kinds of saws by means of a small grindstone or surface, which enters between the teeth of the saw. *Patent completed.*

1033. J. T. ROBSON. *Improvements in sheet-flue and tubular boilers.* (A communication.) Dated May 8, 1858.

This invention consists in arranging the flues of boilers one above the other in a serpentine form, extending from front to back of the boiler. Between these flues, and at intervals, are oval tubes placed vertically, and so that the second row of tubes are seen between the spaces of the front row. Tubes are also placed horizontally at the bend of each flue. *Patent completed.*

1034. A. V. NEWTON. *Improvements in machinery for manufacturing paper.* (A communication.) Dated May 8, 1858.

This invention relates to a mode of varying the width of the paper while the machine is in operation, and during the manufacture. It consists in making the lip or basin which conducts the pulp from the vat to the endless wire apron of two parts, and in connecting these parts with the "deckles" which, as well as the "deckle straps," are by a novel mechanism rendered susceptible of lateral adjustment. It also consists in a novel way of adjusting the usual guage employed for the even distribution of the pulp on the endless wire apron. These improvements are not completely described apart from the inventor's drawings. *Patent completed.*

1035. W. E. NEWTON. *Certain improvements in grinding circular saws.* (A communication.) Dated May 8, 1858.

This consists in grinding one side of a saw at a time while its opposite side is supported by a roll which has a rotary motion at the requisite speed to cause the revolution of the saw as desired. It also consists in the employment of a rotating friction clamp applied to the saw during the grinding, so that it derives rotary motion from the saw through the agency of friction, and by the momentum thus acquired is caused to render uniform, or nearly so, the velocity of the saw, notwithstanding any differences of the thickness of the saw plate, and consequent tendency to variation in the action of the feed roll. *Patent completed.*

1036. A. V. NEWTON. *An improved manufacture of hard and waterproof fabric, and the application of the same to the construction of boats, parts of carriages, and of furniture, portmanteaus and travelling cases, and vessels of capacity.* (A communication.) Dated May 8, 1858.

In carrying out this invention, woven wire cloth or pierced sheet metal is coated on both sides with india-rubber vulcanite compound in a plastic state. *Patent completed.*

1037. G. DAY. *An improved self-acting valve for regulating the flow of liquids.* Dated May 8, 1858.

This invention consists in the adaptation of the ordinary spindle valve to the regulation of the flow of liquids, by adding thereto the common floating ball or an inverted basin. *Patent abandoned.*

1038. R. B. GOLDSWORTHY. *Improvements in machinery for grinding emery and other materials.* Dated May 10, 1858.

This invention consists, 1, in the application of a loose weight or weights to the upper part of a pair of grinding mills, for the purpose of being able to regulate the weight thereof according to the sizes of the emery, or other material to be ground. 2, In a mode of shaping the teeth of the mills used in grinding emery and other materials. These improvements are not described in detail apart from the inventor's drawings. *Patent completed.*

1039. C. F. VASSEROT. *Improvements in the manufacture of umbrellas and parasols.* (A communication.) Dated May 10, 1858.

The inventor forms umbrellas and parasols with the handles out of the centre, that they may be carried directly over the head, (1) by placing the handle and the ribs eccentrically, and diminishing progressively the length of the ribs on nearing the side where the handle is placed: (2) by making the handle with an arm or elbow projecting from the centre directly under the stretchers when the umbrella is open, this arm being hinged with the upper and lower parts of the divided stick, and retained in its horizontal position by a rod connecting the upper and lower parts of the stick. *Patent abandoned.*

1040. C. F. VASSEROT. *Improved driving machinery applicable either for thrashing, winnowing, cleaning, and bruising grain, cutting straw, or other agricultural purposes.* (A communication.) Dated May 10, 1858.

This machine consists of a case having in its bottom, upon a pivot, the main axle which passes through the top, and receives shafts or poles to which the horse or other power is applied. Within the case, and fixed to the axle, is a spur wheel which drives a small cog wheel upon an axle at right angles to the former, and also within the box upon this latter axle is fixed another spur wheel, which gears into a conical pinion fixed to the main transmitting shaft. This shaft passes out of the case, and is connected by riggers, toothed wheels, or pulleys to the machinery to be used. *Patent abandoned.*

1041. W. H. ODDEN. *Improvements in pumps.* Dated May 10, 1858.

Here one piston or plunger is used in combination with a double set of valves, which are fitted to a box or frame so placed that it can be readily fixed or removed by hand. This valve box is divided into two compartments, the bottoms of which are fitted with suction valves, and the tops with delivery valves. The cylinder is placed on one side of the valve box, and the communication between the valves and the pump barrel are formed by two pipes extending from openings formed in the side of the valve box between the upper and lower valves, one of which pipes extends from one of the valve chambers to the bottom of the cylinder, and the second from the other valve chamber to the top of the cylinder. On the up stroke of the piston the fluid is drawn up through the lower valve of the chamber connected with the lower end of the pump cylinder, and on the down stroke the lower valve closes, and the upper valve opens and delivers its water, and at the same time the water is drawn through the other lower valve, which is in communication with the upper end of the pump cylinder, by the down stroke of the piston, and is delivered through the upper valve on the up stroke, and so on alternately. *Patent completed.*

1042. W. C. FORSTER. *An improvement in the manufacture of bricks and slabs for preventing damp in the walls of houses and other buildings.* Dated May 10, 1858.

This consists in the production of a vitrified substance in the interior of bricks or slabs. The outer surfaces remain unglazed, and the absorption of damp from the lower surface to the upper is prevented. *Patent completed.*

1043. I. L. BELL. *Improvements in the manufacture of iron.* Dated May 10, 1858.

This invention is described and illustrated at p. 601 of No. 1846 of the MECHANICS' MAGAZINE for Dec. 25, 1858. *Patent completed.*

1044. J. M. E. MASSON. *Improvements in diving apparatus.* Dated May 10, 1858.

Here the divers descend with a frame, to which reservoirs of compressed air are attached for supplying the divers. The frame is composed of two rectangular gratings, at a distance apart, so that the diver may walk between them. The reservoirs of air are attached to the upper grating, and in order that the divers may be supplied with air at the same pressure as the column of water under which they are working, the reservoirs communicate (by means of pipes with cocks) with two cylinders placed perpendicularly between the two gratings, and open at the bottom; the quantity of air admitted varies with the pressure of the water. The air from the cylinders is transmitted by air pumps (one in each cylinder), through a flexible pipe, to the helmet or dress of the diver, and passes away from his dress through another flexible pipe into an apparatus where it is purified by passing through a shower of a solution of soda, and from there back into the cylinders on which the air pumps work, to be again used. The invention includes other details. *Patent completed.*

1045. R. WILLAN and D. MILLS. *Improvements in machinery or apparatus for drawing in, twisting, or looming textile fabrics.* Dated May 10, 1858.

Instead of drawing the yarn thread or warp through the eyes of the healds by hand, the inventors employ an apparatus worked by power or by manual labour. They place the reed in front of the healds as usual, but below the reed they have a dividing apparatus acted upon by change wheels, so that the divisions of movement may correspond to the spaces of the reed, and the drawing of the yarn through the healds is performed by a falling drum, cam, or eccentric, acting upon mechanical fingers, which push the hooks through the eyes of the healds; and after the yarn is placed upon the hooks they are drawn back again, drawing the yarn with them, which yarn is afterwards passed through the reed by a self-acting hook, the fingers and hooks being connected with the dividing apparatus and all the movements being self-acting. *Patent adandoned.*

1046. W. G. TAYLOR. *Improvements in covering the rollers employed in spinning cotton and other fibrous materials.* Dated May 10, 1858.

This relates to the covering of the rollers to be used in spinning machinery with a leather made from rabbit or hare skin, or similar skins of small dimensions and fine surface, in lieu of ordinary sheep and lamb leather. *Patent completed.*

1047. J. B. PIM and C. PAYNE. *Improvements in recovering useful matters from oil or floor cloth, tarpaulin, American leather cloth, and other like substances.* Dated May 10, 1858.

This consists in recovering the oil or paint from these materials. The patentees use old materials, by preference waste cuttings, which they treat with a strong caustic alkaline solution. With this they sometimes mix ammonia and sulphuric or muriatic acid. *Patent completed.*

1048. P. A. APPARUTI. *A machine applicable for picking and choosing out corn.* Dated May 11, 1858.

The inventor employs a slightly inclined table upon which the corn is laid, and which is moved by jerks. At each jerk the grains of corn are thrown up the incline a short distance (until they fall over the top), while the impurities—which are all supposed to be spherical—will roll down the plane into a receiver. *Patent abandoned.*

1049. J. LUIS. *A mechanical washing apparatus for iron ore and other matters.* (A communication.) Dated May 11, 1858.

This consists in causing the matter to be washed to advance regularly in an opposite direction to the water. *Patent completed.*

1050. G. H. CRESSWELL. *Improvements in pads and apparatus for inking stamps.* Dated May 11, 1858.

In the improved pad printers' ink or thick colouring material is used, and a piece of drugget is thickly saturated with it and placed under the cloth surface of the pad, which is moistened occasionally with sweet oil, rubbed or brushed into it, which softens the ink, and causes it to work up or soak into the upper cloth, and keep it in a proper state for inking the stamps which are pressed upon it. *Patent completed.*

1051. J. H. JOHNSON. *Improvements in madder dycing.* (A communication.) Dated May 11, 1858.

According to this invention the fabrics, which have been printed in suitable mordants, and prepared as usual, are submitted to the action of a hot decoction of garancine, madder, water, air, liquid ammonia, or other equivalent alkali, in proportion of about 10 lbs. of garancine madder to 40 galls. of water, and 1 pint of ammonia or other equivalent alkali. After passing through this decoction, and being acted upon by it for from 3 to 5 minutes, the colouring matter of the madder will be found to be completely fixed on those parts printed in mordants. The addition of about 1 pint of alcohol to the above ingredients will confine the colouring matter of the madder to those portions of the fabric printed in mordants and prevent it from being absorbed by the portions which are to remain white. *Patent abandoned.*

1052. E. FAIRBURN. *Improvements in machinery or apparatus employed in carding wool or other fibrous substances.* Dated May 11, 1858.

This relates to the "single doffer condenser," and consists in having the surface of the doffer cylinder formed of rings (of wood, or other material) for rings of cards of corresponding widths to rest upon, with a flange or shield of thin metal on each side of the rings, projecting to and even with the surface of the cards, leaving a small space betwixt the two flanges. Also, in having similar flanges betwixt rings of cards on the stripping roller projecting above or beyond the surface of the cards, and so arranged that when the stripper and doffer are brought together, the flanges on the stripper will enter into the spaces formed betwixt the flanges or shields on the doffer, thus effectually separating the fibrous substances on the surface of the doffer into strips, the breadths of the card rings, which are then conducted by grooved rollers to the rubbers, where they are formed into slubbings or threads. *Patent completed.*

1053. J. SOUTTER. *Improvements in washing machines.* Dated May 11, 1858.

Inside a trough the patentee fixes a drum consisting of two discs for ends, and several laths let into the discs to form the sides. The drum is rotated by a crank handle. Inside the trough, and near the sides of the drum, he fixes upon springs, rods, bands and blocks, to act as rubbers, and provides means for regulating the distance thereof from the sides of the drum. Inside the drum he fixes projections for stopping or retarding the articles inside the drum to be washed. The laths, or some of them, are free to be drawn apart for placing articles inside the drum and removing them therefrom; also for nipping between them the ends of any large articles to be washed, such as sheets, table-cloths, &c., which are wound round the outside of the drum, and have both sides washed by turning the drum first in one and then in the other direction. *Patent completed.*

1054. W. PARF. *Improvements in metallic and other bedsteads, and other articles of furniture.* Dated May 11, 1858.

Here the sockets for receiving the side and end pieces of the horizontal frame of the bedstead (or other article) are cast in one piece with the legs and the pillars. *Patent completed.*

1055. A. PARKES. *Improvements in the manufacture of tubes and cylinders.* Dated May 11, 1858.

In place of employing hollow cast cylinders of copper, German silver, or other alloys of copper, the patentee uses cast discs, or discs cut from comparatively thick sheets of copper, German silver, or other alloy, and then, in order to produce short and comparatively thick tubes or cylinders, he subjects such disc to a raising process by means of forcers actuated by steam, causing the discs to be raised by dies through which the metal is forced, or, "drawn through." Or the discs may be forced by the steam forcers into hollow dies. When using German silver in making tubes or cylinders, he prefers to cast a short hollow cylinder, and then to extend it into the length and dimensions desired; he also in some cases combines German silver with copper, brass, or other tubes in order to coat the same with German silver. *Patent completed.*

1056. A. PARKES. *Improvements in rollers or cylinders used for printing and embossing.* Dated May 11, 1858.

In constructing rollers or cylinders when shells of metal are used on bodies, the patentee employs a body made of zinc, brass, or of an alloy of copper, or of an alloy of iron and nickel, in combination with an engraved shell or outer surface; and he applies German silver, and also an alloy of iron or nickel in place of the metals heretofore used in the manufacture of such rollers and shells; and in making printing or embossing rollers or shells of copper, or alloys of copper, or of German silver, he first raises a disc of either of such metals by stamping, or by drawing the same through dies, and then extends the same by hammering or rolling, or drawing through dies. *Patent completed.*

1057. W. OLIVER. *Improvements in combining ovens for the manufacture of coke with the furnaces of steam boilers.* Dated May 11, 1858.

This consists in so combining ovens that the operation of making coke shall supply heat for the boilers. When the boiler is cylindrical, he places the coke oven underneath and in front of the boiler up to about one-third of the length. This oven is fed from the front. The furnace for the boiler is placed about the middle of the length of the boiler, and is fed from the side, a bridge with a damper between the two fires being so arranged as to shut off the one from the other when the coke is being withdrawn. The smoke from the coke oven is thus caused to pass over the boiler fire. The bed of the coke oven is built solid in brick, the boiler fire having the usual fire bars. *Patent abandoned.*

1058. R. HALLIWELL. *Certain improvements in mules for spinning and doubling cotton and other fibrous materials.* Dated May 11, 1858.

This is applicable to self-acting mules, and consists, 1, in a combination of machinery for effecting the changes performed by the cam shaft in Robert's Patent Self-Actors. The machinery consists of a lever, or combination of levers, and of a weight connected to the carriage and acting on the levers; this weight, with the levers, act on the machinery for putting in and out of gear the apparatus for drawing up and putting up the carriage, and on the machinery for putting the backing off friction cones out of contact. 2, In the application of duplex levers to which motion is given by wheels in combination with the squaring shaft or other part of the mules, for moving the driving strap on and off the fast and loose pulleys at the commencement and completion of the stretch. 3, In the application of a latch or curved plate and bar in connexion with the strap fork lever for allowing the backing off friction cones to be drawn into contact by a spring for backing off when the driving strap has been moved off or nearly off the first pulley. *Patent completed.*

Digitized by Google

1059. G. LOWRY. *Certain improvements in machinery for heckling flax and other fibrous materials.* Dated May 11, 1858.

This consists, 1, in supporting the troughs of heckling machines (along which the strick holders are traversed) by links or levers to which vibrating motion is imparted by a suitable mechanism; this vibrating motion imparts simultaneously the requisite longitudinal and up and down motion to the trough and strick holders. 2, In a combination of parts for traversing the strick holders along the heckling machine. 3, In a mode of combining two heckling machines, or two series of heckles, with mechanism by which the sticks of flax after being heckled at one end, in passing through the first machine or series, are liberated, then reversed, then taken through the second machine or series by which the other ends of the sticks are heckled. *Patent completed.*

1060. J. M. GILBERT. *Improvements in the construction of cylinders and mandrils used in printing calico and other surfaces.* Dated May 11, 1858.

This consists, as regards the cylinders, in the form given to their interior, which, instead of being one cone from end to end, is formed by two cones having their small diameters towards the middle. The mandril is constructed of three principal parts, two of which are hollow cylinders or shells formed conical on their exterior to fit the interior of the cylinder. The third part is a spindle or shaft made to fit the printing or other machines at the ends, and to carry the two coned shells at its middle part. By means of a right and a left hand thread or screw upon this shaft, and corresponding nuts or threads in the two-coned shells, the latter may be drawn together within the cylinder until a sufficiently tight fixture of the cylinder upon the shells is effected. The same means, but reversing the direction of the action, suffice for releasing the cylinder when required to be removed from the mandril. *Patent completed.*

1061. J. DYSON, E. W. SHIRT, AND H. SHIRT. *Improvements in the mode of rolling strips of steel for crinoline and other purposes.* Dated May 11, 1858.

This applies to a mode of rolling steel of small guage for crinoline, &c., in strips of greater length than the present system admits of. By the ordinary mode steel is rolled in sheets of about 10 ft. in length; the patentees propose after it has been reduced singly to No. 17 guage, to reduce it to the requisite guage in the required lengths by folding each length or strip, and passing it in two or more thicknesses between the rolls. This process will reduce the strip to so small a guage as to obviate the necessity of cold rolling. *Patent completed.*

1062. J. HENDERSON. *An improved apparatus for measuring fluids.* Dated May 12, 1858.

This relates to apparatus to be applied to taps, or pipes, for measuring off separate portions of fluids, and may be used by druggists, &c. According to one modification it consists of a glass vessel fitted to the outflow pipe, and communicating by its bottom with the pipe at a point between two stop cocks fitted to the pipe. The glass vessel is graduated to show the quantities of liquid when at various levels. In using the apparatus, the inner stop-cock between the reservoir and the glass-measuring vessel is just opened, the outer being closed, and the liquid is allowed to flow into the measuring vessel until it attains the level corresponding to the quantity wanted to be drawn off, or measured. The inner stop is then closed, and the outer one opened, when the liquid in the measuring vessel flows off into another vessel. In a modification of the apparatus for measuring gas, the measuring vessel is by preference inverted, and the gas is made to displace water when flowing into it, the liquid refilling the measuring vessel on the egress of the gas. *Patent abandoned.*

1063. L. DURAND. *An improved tubular steam generator.* Dated May 12, 1858.

This consists of a steam generator composed of one upper and two lower longitudinal tubes of comparatively large diameters, and communicating with each other by a number of very small tubes arranged side by side transversely, and in a zig-zag form. *Patent completed.*

1064. M. DIOSY. *Improvements in machinery for preparing or manufacturing granulated potatoes for preservation.* (A communication.) Dated May 12, 1858.

This relates to machinery for preparing granulated potatoes for preservation, and is not described apart from the patentee's drawings. *Patent completed.*

1065. J. A. DETROYAT and F. TEUBERT. *Improvements in apparatus for cleansing hair combs and other similar articles.* Dated May 12, 1858.

The inventors mount, on a handle, a spring band of steel, curving upwards, and terminating at each end in a roller or cushion; towards one of these the handle will slightly incline, and between the lugs of that one the shank ends of a series of steel blades or teeth will enter and be secured by a spindle passing from end to end through the cushion, the other end of each of these blades terminating with a hook, which, on the blade being depressed, will enter between the lugs of the opposite cushion and fasten on to the spindle passing through it. In use, the cleaner should be held in the left hand and the comb drawn perpendicularly along the blades in the direction of the holder. To clean the apparatus, press each cushion slightly inwards and, passing the hand beneath the blades, lift and clean them one after the other. *Patent abandoned.*

1066. J. A. CLARKE. *Improvements in compositions for coating vessels' bottoms.* Dated May 12, 1858.

The patentee employs white lead (free from admixture with carbonate of barytes, oxide of zinc, &c.), ground in naphtha to a paint-like consistence, adding thereto rosin varnish, by which he obtains a composition capable of being used either cold or hot for paying or painting over vessels' bottoms, as a preservative coating. *Patent completed.*

1067. W. MARK. *Improvements in roofing and other tiles.* Dated May 12, 1858.

This consist, 1, in forming tiles for roofing, &c., with a feather or projecting rib along one of the edges, the opposite edge being formed with a channel or groove situated at the reverse side of the tile, and made to fit upon the feather or rib of the next adjoining tile. At the under side, between the two edges of each tile, and parallel thereto, is a recess (extending partly across the tile) for lying over a portion of the joint of the adjoining tiles of the next row. It has reference, 2, to tiles used in the formation of gutters, spouting, &c., and consists in forming the body thereof hollow, or in other words, as a double shell with a space between the two thicknesses. *Patent abandoned.*

1068. J. WEST. *A mode of covering and securing water-taps and branches.* Dated May 12, 1858.

In the ordinary way in which water-taps are placed, and also the extremities of stand or branch water pipes, they are subject to be destroyed by accident and other causes, and are also easily removed. To guard against these evils, the patentee proposes to apply the following means:—In front, and over the tap or mouth of the pipe, he fixes a plate of cast iron, and the face of this plate he secures to the wall or post on which the tap is fixed. Sometimes he encases the tap. The outlet of the tap discharges into a spout or mouth in the face-plate. Anywhere on the said face-plate he forms a slot for admitting the key or lever which opens and shuts the water-way. Also in some cases he fixes in the rear of the face-plate a spring so arranged as to press against the lever or key when it has opened the tap, urging it back again whenever the force which opened it is removed and thus prevent the water from being wasted. He proposes also to form another aperture in the face-plate through which access may be had so as to screw or unscrew the plug or valve of the tap, and render it unnecessary to remove the plate. The inlet or junction of the tap is attached to a tube of iron, &c., enclosing the supply pipe which may be let into the wall post or plate, and covered over with cement or other material. *Patent completed.*

1069. A. H. ROGERS. *Improvements in lubricators.* Dated May 12, 1858.

The lubricating vessel is attached to a revolving wheel, the boss of which fits on a plug fixed to the cap of the shaft to be lubricated; the lubricating material enters through a hole in the boss, and is delivered into a recess in the plug, from which it passes through a side passage in the boss to a hole in communication with the passage, running from one end of the plug to the other; this passage admits air, and affords facility for cleaning. The requisite rotary motion is given to the boss or to the plug by any means so as to deliver a supply of material at intervals to the shaft. The improvements in lubricators for connecting rods, slides, &c., having a vibrating motion, consist in the use of a plunger with recesses; this plunger is raised and lowered by a ratchet wheel, and in descending delivers a portion of the lubricating material to a chamber (furnished with a set screw to regulate its capacity) and in descending the lubricating material in the chamber descends on the article to be lubricated. *Patent abandoned.*

1070. J. SHARPLES. *Improvements in extracting moisture from and drying porous and fibrous substances.* Dated May 12, 1858.

This consists in extracting moisture from and drying fabrics or other porous and fibrous substances, by forming a partial vacuum on one side, and admitting air, either heated or otherwise, at the other side; the current of air passing through the materials removes the moisture therefrom. *Patent completed.*

1071. R. KNIGHT. *Improvements in apparatus for refrigerating, also for bottling ærated liquids, and in the preparation of storing salts for the production of artificial mineral waters.* Dated May 12, 1858.

The apparatus for refrigerating is formed of a metal vessel having an external cover, and in the space between the vessel and the cover is a bag of flannel or felt fixed around the lower edge of the inner vessel, and against the surface of the external cover is fixed a lining of felt or flannel. Between the inner surface of the bag and the outer surface of the inner vessel is placed ice. The apparatus for bottling ærated water consists of a moveable stand or block (to receive a bottle) fixed to the upper end of a rod, which is guided in its passage through a table or bench. This rod and stand or block is acted on by the foot. Above the block is fixed a socket, through which the corks are forced into the bottles. The corks are forced through the socket and into the bottles by a ram, or forcer at the end of a bar which moves vertically in guides, and receives its motion by a lever handle. To convert ærated water into artificial mineral waters the constituent salts in the exact proportions required for a given measure of water are mixed together and stored in small glass tubes or vessels, which are closed at their outer ends by corks so as to keep them dry. The patentee produces any of the artificial mineral waters by placing the salts into an open glass or vessel and drawing on to them ærated water, the salts being prepared so as to dissolve clear, and they are mixed and kept closed from the air till about to be used. *Patent completed.*

1072. J. G. JACKSON. *A method of carrying roads over (or through) land covered with water.* Dated May 12, 1858.

The inventor constructs and places upon the surface of the water which covers the land to be crossed a water-tight tube. The railway is laid down in the interior of the tube, which may be enclosed in another similar tube for security. Pieces of glass, &c., may be let into openings to admit light. When completed the tubes are to be sunk in the water on to the solid ground, which must be prepared to form a solid bed to receive them. *Patent abandoned.*

1073. J. BIGGS. *Improved apparatus for compressing vegetable and other substances.* Dated May 12, 1858.

The object here is to facilitate the pressing of tobacco. The inventor uses a hydraulic press fitted with a tram way, to receive the mould and facilitate its being brought to and from the press. To the side standards of the press he attaches a pair of rails or ways and turns up their ends to prevent the mould, which is mounted upon wheels, from running off the ways. Midway between these ways stands up the hydraulic ram, and immediately above the ram a pressing block is suspended from the cross head of the press. This block fits the mould, and is intended, as the charged mould is raised up by the ram, to enter the mould, and compress the material contained therein. *Patent abandoned.*

1074. A. L. LIETOUT. *Improved portable medical and hygienic gymnastic apparatus.* Dated May 12, 1858.

This apparatus consists of a foundation bed on which four uprights are placed. These four uprights serve as a support for all the ordinary parts used for gymnastic purposes, comprising a ladder placed at the side, an arm chair for straightening the body, a pulley or tackle for raising weights, a rope ladder with knots, rounds, blocks, &c., a horizontal bar, a swing bar, a horse, &c. The whole apparatus is arranged so as to be capable of disconnecting, folding up, and placing in a case. To mount it it is merely necessary to join the pieces and place it on a level surface.—*Patent abandoned.*

1075. J. S. and W. H. BAILEY. *Improvements in machinery for preparing and combining wool, cotton, and other fibrous materials.* Dated May 12, 1858.

This relates to a combination of circular or endless guides, grooves, or channels, with rotary comb frames for controlling the motion of the taking combs or instruments on their own axis or points of motion. The guides, grooves, or channels are mounted on an axis excentric to the comb frame but with which they rotate and perform an equal number of revolutions; crank pins project from the lever arms fixed on the axis of the combs or taking instruments, which pins are received in the grooves or channels; stops are placed in the grooves or channels; the crank pins coming in contact with the stops carry the grooves or guides round with them, but these, by reason of their excentricity, control the lever arms fixed to the comb axis, and cause them to assume the different positions required. It also relates to combing wool, &c., by operating on the material by taking instruments individually or in combination with other instruments, whereby the material is taken from the feeding apparatus and transferred to the receiving-comb, so that the end of the material which is last in leaving the feeding apparatus shall become the first end when delivered on to the receiving-comb. It further relates to the application of a pressing surface, to exert a pressure on card surfaces in carding or combing machinery, which has a tendency to bend the wires to their original form after they have been straightened by contact with the receiving-comb or surface, or the material that is thereon. The patentees also apply emery for sharpening the card teeth, which is effected by rubbing contact. *Patent completed.*

1076. J. HAMILTON.—*Improvements in the preparation and use of starch for manufacturing, bleaching, and finishing purposes.* Dated May 12, 1858.

Instead of finishing and drying up the starch, as is commonly done, the process of manufacture is carried on no further than the actual deposition or solidification of the starch, when it is at once taken for use without any further preparation. Starch used in this way is most effective in its action, whilst it is peculiarly economical. *Patent completed.*

1077. W. SIMONS.—*Improvements in the construction of iron ships or vessels.* Dated May 13, 1858.

This relates to arranging the deck beams of ships diagonally or with the reverse inclines, so as to gain superior strength. Each line of beams is disposed so that the individual beams lie at an angle with the keel line of the ship, and in every deck the direction of the angle is reversed. It also relates to the diagonal disposition of the staunchions, each staunchion or hold-fast beam or bar being inclined or set diagonally in one or more lines, the lines being reverse to each other, and the bars being attached at the intersections and at their upper ends where they join the beams. It also comprehends inverting the knees of the ship, that is to say, the knees are disposed above instead of below the deck, and iron plates are laid above or over the lines of knees throughout the ship fore and aft. *Patent abandoned.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JANUARY 21, 1859.

CAPTAIN FISHBOURNE ON NAVAL ARCHITECTURE.

A LETTER printed for private circulation, entitled "Observations on the present state of Naval Architecture, addressed to the Right Honourable Sir JOHN PAKINGTON, Bart., M.P., First Lord of the Admiralty, by Captain E. GARDINER FISHBOURNE, R.N.," has lately been producing some sensation among certain ingenious naval men and others who persuade themselves that they understand naval architecture. We do not propose to act less wisely than Captain FISHBOURNE by publishing the letter, or even by making known to the world the opinion which he entertains of the efficiency of the English Navy and the ability of the Constructive Department of the Admiralty. But as the letter is addressed to a public officer in his official capacity, we think ourselves at perfect liberty to criticise the principles laid down by Captain FISHBOURNE in establishing his charge against the Naval Architects at Whitehall.

The Lords of the Admiralty are, of course, perfectly competent to judge of the value of his facts, some of which appear to us to be very recklessly stated. The *Orlando*, for example, is said to be 360 feet long, and as, according to him, *unsteadiness* varies directly as the length, she cuts a sorry figure in the comparison he makes. But when we remember that her length is 300 and not 360 feet, matters assume a different complexion. Again, in making unfavorable comparisons between the *Diadem* and *Galatea* and some French ships, he reasons on the assumption that the former vessels are armed with 8-inch shell guns; whereas we are quite sure the *Diadem* has 20 and the *Galatea* 24 10-inch shell guns.

Captain FISHBOURNE is of opinion that for war purposes the modern ships of the Royal Navy "are, in respect of that indispensable quality, *steadiness of platform*, very deficient as compared either with those of foreign nations or with our own of the old and unwisely rejected construction."* Regardless of stability, *i. e.*, the power of resisting an inclining force, the writer directs his attention to the amount of the angle through which the ship rolls in a given time in a rough sea as the measure of her steadiness. That steadiness is a most important quality in a ship of war we readily admit, but Captain FISHBOURNE has greatly underrated the difficulties which surround the question. Let us observe what has to be taken into account in considering the rolling motion of a ship:—When a wave rolls across a vessel, climbing up above the water level on one side, and falling considerably below it on the other, the balance between the supporting forces on the two sides of the ship is destroyed, and her line of support—passing vertically through the centre of gravity of the *displacement*—will pass on one side of the centre of gravity of the *ship*. There will then be an immediate effort, dependent on the amount of stability in the ship, to correct this, and the ship will roll towards the depressed part of the wave. The angle through which she will roll in the attempt to restore the statical equilibrium, and in the subsequent oscillations necessary to destroy the *vis viva* which has been generated, and also the time of these oscillations, will depend on the weights—and possibly, too, on the elasticity—of every portion of matter in the ship, together with its position, both in a vertical and in a horizontal sense; on the relative positions of the meta-centre and the centres of gravity and of buoyancy; on the resistance offered by the outer surfaces of the ship to rotary motion in the water, and the amount of friction upon them; and, if the ship is under sail, on the resistance of the air upon it, a resistance which varies in amount with every angle of inclination. Captain FISHBOURNE, however, feels assured that there is "nothing connected with Naval Architecture but might be resolved into general laws." But, although there certainly can be no doubt that all the forces which act upon a ship, and produce or retard motion, are under the influence of immutable laws, very grave doubts may be entertained as to whether we shall ever comprehend those laws, and be able to calculate their effects. NEWTON, and his scientific successors, in their Hydrodynamic studies, have attempted to force from nature these secrets, and have failed. The darkness in which they have ever been involved is still impenetrable. With this statement of the case Captain FISHBOURNE will not agree. He thinks he has solved the most difficult problem of all. Let us examine his analysis of the question. He says:—

"A ship or other floating body when at rest is subject to, and is retained in that state by the balance of forces, resolvable into two, equal and opposite; that of gravity, which is equal to the total amount of water which the ship displaces, in other words, is equal to her weight, together with that of her contained weights; and the sustaining pressure of water on the outer surface of the parts immersed."

What does all this mean? The force of gravity is equal to an amount of water, or in other words, to the weight of the ship and contents, and these are balanced by the sustaining pressure of water! This is an odd way of stating the principle that the weight of a floating body is equal to the weight of fluid displaced by it. But to proceed with the argument,

"The directions in which these pressures act are *perpendicular* to the varied surfaces, or to the indefinite number of *points** that go to make up the curves, forming the envelope of the body immersed; consequently, as these surfaces are changed in form, either by an actual change in the conformation of the ship or floating body, or from an inclination of the body around a horizontal axis, that immerses a different form; so the directions of these pressures are changed, and with them is moved the position of that mean centre at which lines drawn from these numerous points of pressure would meet. A floating body is thus as effectually sustained by the joint action of these pressures as though the water were rigid, but equally with any other body otherwise sustained when a third force is introduced, such as a horizontal push above or below the centre, or the withdrawal of or addition to the support on one side or the other, motion round a longitudinal axis will be communicated. Now, owing to the fact that these pressures are confined to the outward surface or periphery of the body when motion round a longitudinal axis is generated, the position of that axis will depend *much* upon the form, and will vary considerably according to the configuration of the surfaces in contact with the water, so that though there may be, and undoubtedly is, easy play amongst the particles from which these pressures proceed, yet if the ship or other body be considered at any given angle of inclination, the result of that motion, it will be found that it has rolled round an axis, with results analogous to those which take place when a body has been rolled on a rigid surface, and the vertical position of the axis would vary in each similarly, though not equally, with the inequality between the half-breadth and the depth."

We hesitated for some time time before we could determine to trouble our readers and ourselves with the above quotation; but we thought we should not be doing justice to Captain FISHBOURNE if we did not give his argument complete. He goes on to say:—

"If we take a homogeneous cylinder, the specific gravity of which is such that, when immersed, it will sink to its axis, we shall find—owing to the fact that the radii or the lines of pressure meet in the axis, and are coincident with the centre of gravity—that though it be rolled on a rigid surface or turned round a horizontal axis to any angle in water, the latter centre will not rise or fall. But if we take an eccentric body of an oval form, whose depth is only half its width, and the specific gravity half that of water, when floating, half will be immersed—and this be turned round a horizontal axis, whether floating or supported on a rigid surface, it will revolve round an axis situated somewhere between the centre of gravity and the surfaces of pressure."

With reference to the first of these examples, Captain FISHBOURNE seems to think that the specific gravity of the cylinder has something to do with the result mentioned, whereas—the section being circular—the centre of gravity will remain at the same height whatever be the height of the water-line! In the second example he makes a grave error, vitiating the whole of his reasoning. An ellipse of half the specific gravity of water, will have its centre of gravity in the water-line however much it may be inclined, for all straight lines through the centre of gravity cut off the same area: it will therefore be under exactly the same conditions as the cylinder. But applying these supposed discoveries to the ship. He says:—

"If we suppose this form [*i.e.*, the oval form] given to the ship's bottom, and the longer axis to coincide with her water-line, and she be rolled on a rigid surface, her centre of gravity would rise with each angle of inclination till the longer axis was perpendicular; the maximum height of which rise would be the difference between the half-lengths of the longer and shorter axis: in other words, a height equal to the difference between the half-breadth and the immersed depth, and the same effect, differing only in degree or amount, would occur if a ship of that form were inclined in the same way.

"This establishes that *the form of ship most suitable for easy and limited rolling motions is that of semicircles for her cross-sections*, as in that form the vertical motion of the centre of gravity consequent upon rolling motions, which must occur whenever there is a sea, will be a minimum, while *the amount of rise and fall of this centre will increase as the immersed depth is less than the half-breadth.*"

Both these conclusions are based on what we have shown to be false assumptions, and they are themselves both false and absurd, as any naval architect would have seen in a moment. The amount of the vertical motion of the centre of gravity is governed entirely by the position of this centre, and by the form of the vessel between wind and water, and is affected in no other way by the form of the sections below this, or by the relation between the breadth and depth. Vertical motion of the centre of gravity may be altogether avoided with *rectangular* sections, and with a breadth as great as you please. The midship bodies of the ships built by the members of the late school of Naval Architecture, and of nearly all those designed at the Admiralty since the accession to office of the present Surveyor, have been made either vertical or circular in the region of the load-water line, for the express purpose of avoiding the defect which Captain FISHBOURNE imputes to them, and for which most of the ships built by the former Surveyor were remarkable.

Captain FISHBOURNE says, however, "It is owing to the principle just explained that

* The reference here is to ships built before the time of Sir William Symonds.

* The Italics are our own.

Digitized by Google

vessels of small draught of water, as compared with their breadth, are so uneasy." Further, the *Napoleon* is said to be deeper than the *Agamemnon*, and her cross sections less eccentric, and from both of these causes her motions are pronounced *less rapid and less extensive;* and towards the close of the letter the author says :—

"I have shown that to obtain the steadiest platform, the immersed body must approximate to the volume and form of a semi-cylinder; how far this is from being realised in the ships built during the last ten years may be gathered from the following dimensions."

Then follows a list of foreign and old English ships, with which our modern ships are made to contrast unfavourably with regard to steadiness, because the ratio of breadth to depth is greater in the latter.

Not content with this exposition of the causes of deep rolling, Captain FISHBOURNE makes a formula by which its amount and velocity may be determined. One would naturally expect to find in a formula based on such principles some index to the form, and also to find the proportion between breadth and depth so embraced that the discovered amount may be seen to diminish as the sections approach the semicircular form. But, strange to say, no notice whatever is taken of these things. The *numerator* of the fraction which is said to be proportional to both the amplitude and time of an oscillation, is the *length* of the ship, multiplied by the cube of the *extreme breadth;* and the *denominator* is the sum of the weights of the engines, coals, stores, and armament; so that the form of the section and the depth may be anything whatever. But that the formula is incorrect is evident enough from the consideration that there is no more reason for supposing the *lateral* oscillations of the ship to increase in amplitude according to the cube of the breadth, than for supposing the amplitude of the *longitudinal* oscillations to increase with the cube of the length—a supposition which is ridiculously wide of the truth. And again, it is not difficult to see that an increase of breadth will not always increase the rolling; on the contrary, we can imagine the breadth to be increased until, at the attainment of very great dimensions, the ship or raft became steady, and did not roll at all. Let us now observe how he applies this remarkable formula. He says :—

"On the other hand we may compare the *Orlando*, a new class 50, with an enemy's *sailing* vessel; the former is 360" [300] "feet long, the latter we shall suppose to be 200 feet by 48, and give her precisely the same armament as the *Orlando*.

Weights of each.	*Orlando.*	Enemy.
Armament, Stores	1,400	1,400 tons
Engines and Coals	1,500	
	2,900	1,400

If the vessels have the weights assumed above at starting from port, then we shall have as their ratios :—

$$Orlando\ \frac{360\times52^3}{2,900}=17,450.\quad Enemy's\ \frac{200\times46^3}{1,400}=13,900,$$

that is, the motion of the former will be greater than that of the latter as 175 to 139, and if the former has used half her coals, these motions will be as 202 to 139."

He says again, with reference to this formula, that neither the *Diadem* nor *Galatea*, the armaments of which consist of 10-inch shell guns and heavy 68-pounders, would dare to approach a French *sailing* frigate armed with 30 guns like our long 32-pounders, and with 30 30-pounder short guns or carronades, in consequence of the superior steadiness of the French battery, as will appear, he says,

"From the following table, which shows the relative amount of motion of the ships specified, and which is, indeed, a measure, in an inverse ratio, of the precision of fire possible in each,

French 120 gun ship	...	...	...	125
„ 102 „ „	...	...	...	130
„ 86 „ „	...	...	...	118
Diadem	...	...	...	176(!)"

We cannot seriously discuss the gallant officer's disquisition further. We have said sufficient to show that his views of established science are false, and his speculations altogether baseless. In one respect, however, we can agree with Captain FISHBOURNE,—that is, in regarding the systematic collection and arrangement of facts connected with naval architecture as a matter of prime importance, demanding the attention not only of the Government and of private shipbuilders, but of every man who has to contribute towards our constantly increasing Navy Estimates; and we are glad to find that there is a movement among the scientific naval architects in and about town in that direction. We shall offer them our most cordial support. Captain FISHBOURNE advocates—and, we believe, has long advocated—the establishment of a Statistical Office "for the collection, arrangement, and discussion of facts connected with naval architecture." We are inclined to think, however, that this matter would be better out of the hands of the Government. If it were undertaken by them, the scientific materials and facts would flow into the huge official machinery to the pecuniary benefit of younger sons, and of illustrious noodles not a few, to be faithfully recorded in thick folios, and deposited in secure presses, to the mystification of all who were privileged to examine them, and to the mortification of those who were not. Things of this kind must not be left to the management of clerks, or even of "young officers," as Captain FISHBOURNE innocently proposes. If our remarks here are worth anything, they must show not only that the work needs to be done, but that none but carefully educated naval architects can be entrusted with it.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

ORDINARY meeting, Dec. 28, 1858. W. Fairbairn, F.R.S., &c., President, in the chair.

The President stated that it was his painful duty to announce a loss which the Society had sustained in the death of their friend and colleague, the late Rev. H. H. Jones, M.A., F.R.A.S., &c., on the 21st inst. For upwards of twenty years he took an active part in the business of the Society. He served the office of Honorary Secretary from two to three years, in conjunction with Dr. Angus Smith; and on every occasion Mr. Jones as an ardent lover of science faithfully discharged the duties of that office. A sympathetic resolution was then unanimously passed by the Society.

Mr. Binney brought before the Society some *Lithographs of Brooches and Ornaments.* Mr. F. M. Jennings, M.R.I.A., F.G.S., some time since travelled in Morocco. Whilst there he collected a series of brooches and ornaments in common use in that country. These are very similar in form to specimens of ancient Irish brooches and ornaments now in the Museum of the Royal Irish Academy, and are, in the opinion of the author, another evidence of the trade anciently existing between the Phœnicians, their colonies, and Ireland. The drawings exhibited show the African and Irish ornaments. Mr. C. J. Julote, a Manchester gentleman, who has resided in Morocco, says these brooches, &c., are not uncommon in Algeria and Morocco. They are made by *Moorish* and *Jewish* workmen. All the designs acknowledged as *Moorish* have reference to some geometrical figure. In others, some have waving lines with branches, others have reference to the Cross. These designs may be traced to Christian workmen (Spaniards, Portuguese, Italians, and Maltese) who have, from time immemorial, occasionally resided in these countries; indeed, many of them have adopted the manners and religion. The people of Susa consider themselves a distinct nation, have a distinct language, said to somewhat resemble the *Irish*. They used to keep up an intimate relation with the Canary Islands. The above people, of which very little can be learned, owing to the jealousy of the Moors, are an active, intelligent class, sometimes employed by European settlers as trusty servants, and very seldom abuse the confidence placed in their fidelity. They are the celebrated snake charmers, vaulters, skull and choppers, of whom we read; and they are the carriers to Wednoor Mogador. If we could induce the Emperor to allow us to trade to Agadeer, a large and valuable trade from that place to Senegal and Timbuctoo might be carried on. At present it is not safe to enter the country.

Mr. T. T. Wilkinson, F.R.A.S., laid before the meeting a selection of *Geometrical Investigations*, from the papers of the late Mr. Henry Buckley, of Wood House, Delph. Mr. Buckley (a pupil of the late Mr. John Butterworth, of Haggate, near Oldham) was distinguished for his knowledge of the Ancient Geometrical Analysis; he died in July, 1856, and might almost be considered as the last of the Oldham group of self-taught mathematicians. He corresponded to the *Diary*, the *York Courant*, and the *Educational Times*, both in his own name and under assumed signatures. Since his death, Mrs. Buckley has consigned the MSS. to Mr. Wilkinson, who, on the suggestion of the President, promised to make a selection for the Society at no distant period.

A paper by Mr. Morris was read "*On the Practicability of Counteracting a Portion of the Resistance at the Head of a Ship, by employing a Revolving Conical-Bow to work a Stern Propeller.*" Communicated by David Chadwick, F.S.S., Assoc. Inst. C.E. The following extract is sufficient to illustrate the author's notions :—"No one, at this day, will imagine that any power can be created; but a great deal is lost, and perhaps some may be saved. The ordinary head of a vessel may be regarded as a wedge employed to split open a channel for her. In her voyage, the water is at every moment making an effort to press the two sides of the wedge together, and yet no attempt has been made to economise this constantly-sustained pressure. Now, a cone is a wedge in every direction—a circular wedge—and by surrounding it with spirals, it will become a revolving wedge, the flanges themselves constituting an active part of it. I submit that by driving through the water an immovable wedge, a large portion of the motive power is wasted; but by employing a revolving bow, that wasted portion may be economised. I believe that the result may be thus stated :—Resistance of plain conical-bow 100 + 10 for resistance of flanges + 5 for friction = 115. Available power, one-half of 100 = 50 − 15 = 35 clear again. This is upon the supposition that the revolving-cone is only checked to the extent of half the speed due to the resisting water." Several experiments were tried. A laden model was balanced in the stream by a weight, and then a string attached to the shaft of the propeller, which revolved six times the speed of the bow. The string was fastened ahead, and the model wound itself forward. A second model was placed in the stream without a balance-weight, and it pulled itself ahead by a string fastened to the cone-shaft; and so on. In the discussion which followed the paper, the President said it was impossible to take power from the water without decreasing the speed of the ship to the extent of the power gained. Dr. Joule thought that the effect of the revolving-bow might in some cases be to make a bad bow better; but denied the possibility of its producing any but a retarding effect if applied to a ship possessing good lines.

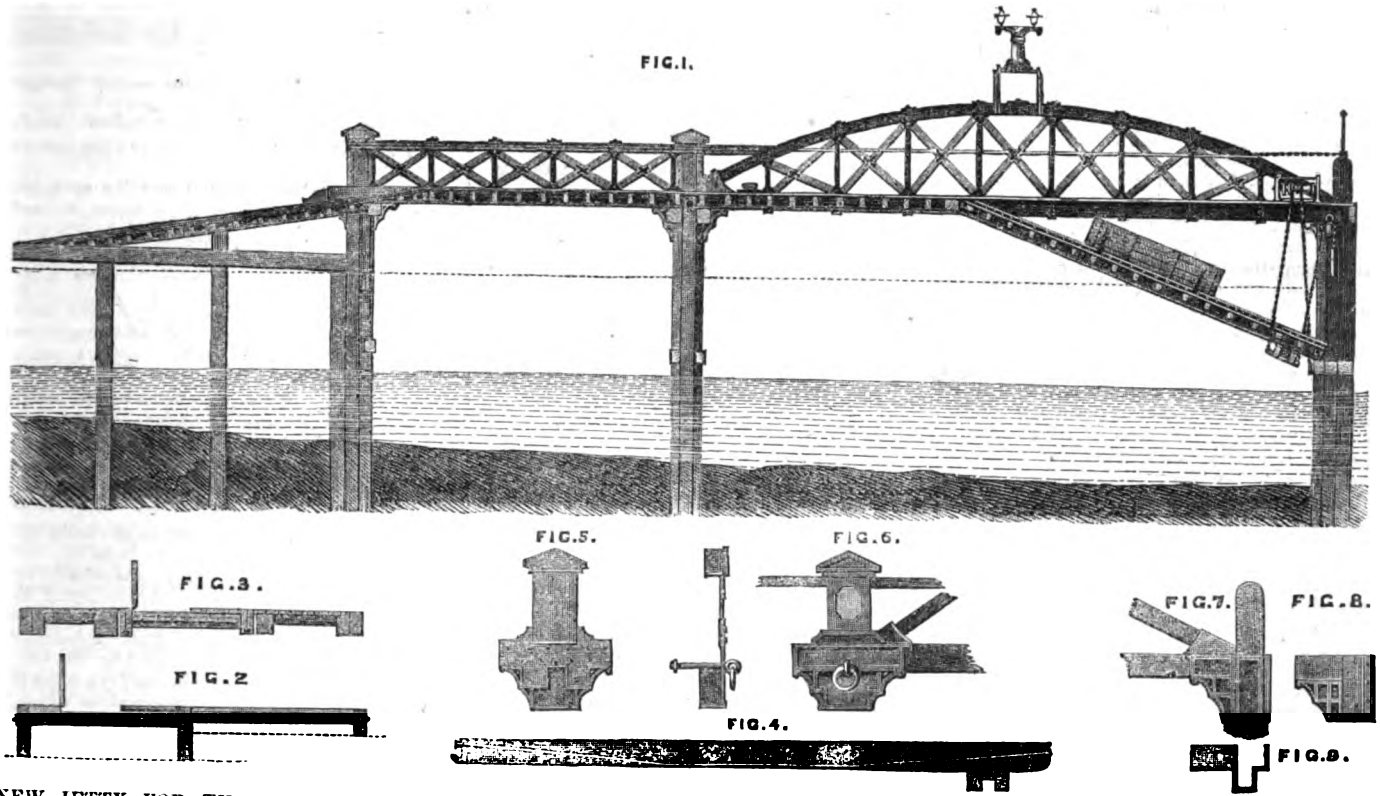
NEW JETTY FOR THE BRITISH, IRISH, AND FOREIGN STEAM-PACKET COMPANY.



NEW JETTY FOR THE BRITISH, IRISH, AND FOREIGN STEAM-PACKET COMPANY.

AMONG the most recent improvements designed to facilitate the shipment and unshipment of goods on the banks of the Thames, without obstructing the river traffic, is a very well-contrived jetty, designed by Mr. R. Davison, C.E., of London-street, City, for Messrs. J. Hartley and Co., of Leadenhall-street, who represent the above-named company. The jetty, which was suggested by Mr. Price, the active manager of the company, is constructed in front of the large warehouses on the Dublin-wharf, immediately below the entrance to the St. Katherine's Docks, and has met with the entire approbation of the Conservancy Board, who exert themselves strenuously to discharge their duties efficiently, and to encourage improvements brought forward by private enterprise. The construction and erection of the jetty have been carried out with very remarkable skill and rapidity by Messrs. Gladstone and Co., contractors and engineers, of John-street, Minories. The contract was not taken until the end of September, and the first pile was not pitched until the 11th of October; yet, on the 9th of November the jetty was brought up the river on barges, and on the following day was landed on the piles, and secured in its place. It was in use by December. This was certainly very rapid work, and does great credit to Messrs. Gladstone and Co. The progress of the jetty up the crowded pool, floated on barges, and towed by steam-tugs, was a remarkable circumstance, and could not have been effected without great skill on the part of Mr. T. N. Gladstone, who superintended the operation, or without the considerate care of the harbour-master, who kept the river as clear of traffic at the time as possible. The new jetty is illustrated in the annexed engravings, fig. 1 being a side-elevation of it. It extends into the river, at right angles to the warehouses, upwards of 110 feet, and its platform is 20 feet wide. It rests upon a group of piles at its outer extremity, and 55 feet towards the quay are other piles, and again at 27 feet are more. The whole is strongly tied together. The old landing forms two openings, the one 55 feet in the clear, the other 27 feet, the greater space being strongly supported by trussed arches of timber, and tension-beams of 16½ inches square. At the river end of the jetty is a moveable gangway 35 feet long, which, though weighing more than four tons, one man can raise or lower to the angle required, according to the height of the water or of the vessel using it. The whole is bound together by cross timbers, braces, &c., so that it is calculated to bear much more than any load likely to come upon it. It is also provided with moving-posts, tie-rods for cattle, and such requisites as will tend to economise in moving the traffic over it. Fig. 2 is a section of the inner end of the jetty, showing the manner in which hinged flaps (one of which is shown open) are fitted to guide the cattle off and on. Fig. 3 is a section of the outer end, through the moveable gangway, which is fitted with similar flaps. Fig. 4 is a view of one of the trussed side-timbers of the moveable gangway. Fig. 5 is an inside view, fig. 6 an outside view, and the fig. between a section of the cast-iron caps of the centre piles. Figs. 7, 8, and 9, are respectively outside, inside, and plan views of the cast-iron caps for the outer piles. By aid of these details the whole construction of the jetty will be readily understood. By the removal of the old dummies formerly employed, a new and clear passage at all times is now open for boats and barges to pass freely under the jetty at all times of tide for the full length of the projection; and as it rests six feet clear above Trinity high-water mark (indicated by dotted lines in fig. 1), there is now little or no impediment to the inshore navigation. By the removal of the dummies, also, which kept back much of the sewage water, perfect freedom of motion is now given for this to pass freely away. To the proprietors it affords some 1,100 feet additional quay space always available, and upon it they can secure a whole cargo of beasts, thus vastly facilitating the discharging from vessels in the safest manner.

THE ASSOCIATION OF FOREMEN ENGINEERS.

A GLOOM has fallen, at the very dawning of the new year, upon this rising association. Mr. George Sheaves, the founder and first chairman of it, died on the 8th instant, the very day appointed a month previously for the meeting of the society. The lamented gentleman had presided at the December meeting; and, although suffering from indisposition at that time, subsequently recovered, as all thought, his usual good health. A day or two previously, however, to the fatal one, Mr. Sheaves suffered a relapse, from which, unfortunately, no medical skill, nor the anxious solicitude of loving relatives and friends, could rally him, and the end came, as we have stated, on the 8th. At the meeting on the evening of that day most of the members heard, for the first time, of the loss which, individually and collectively, they had sustained. The shock thus communicated may be imagined. The secretary performed the routine duties of his office in the midst of profound silence, and Mr. Joseph Newton, who had declined taking the vacant chair under the painful circumstances, after proposing that a letter of condolence should be written to the widow of Mr. Sheaves, who is unfortunately left with a young and helpless family, moved an adjournment to February. Both of these propositions were carried *nem. con.* Mr. Sheaves had occupied the post of manager for Messrs. Grissell, of the Regent's Canal Iron Works, for many years, and was universally esteemed. His funeral took place at Abney Park Cemetery on the 14th inst., and was attended by many friends of the deceased, and a host of workmen from Messrs. Grissell's.

We have to record with regret the decease, on Monday last, of George Mills, Esq., late Engineer of the Royal Mail Steam Company. Mr. Mills was connected with the Company from its establishment and acted as their Chief Engineer until within the last twelvemonths, when ill health compelled him to retire upon a handsome pension generously awarded by the Company for his past services.

THE THEORY OF NAVAL ARCHITECTURE.

No. II.

IN constructing a ship, the drawing is made to give the form either at the outside of the planking, or at the outside of the frame-timbers. If it be made to the outside of the timbers, before any exact calculations can be made respecting the ship's displacement, or any other of her qualities, it will be necessary to obtain the form at the outside of the planking—that is, in technical phraseology, to *put on the planking*, in order that we may operate upon the form corresponding to the actual surface of the ship when she is afloat. The method for putting on the planking will be given hereafter; for the present, in the investigations which we are about to make, we shall presume that our drawings give the form at the outer surface of the ship.

But before proceeding with these investigations it is necessary to explain that the drawings of a ship made to the outside of the frames — called the BUILDING DRAUGHTS—have for their planes of projection, 1. a vertical longitudinal plane passing through the middle of the ship, dividing it into two symmetrical portions; this corresponds with the SHEER PLAN: 2. A plane perpendicular to this, passing through the upper edge of the rabbet of the keel, corresponding with the HALF-BREADTH PLAN: 3. A plane through the broadest part of the ship perpendicular to each of the other planes, corresponding with the BODY PLAN. The drawings giving the form at the outside of the planking, denominated the CONSTRUCTION DRAUGHTS, have the same sheer plan as the "building draught," but the Load water section, or a plane parallel to it, becomes the half-breadth plan, and a plane perpendicular to each of these through the broadest part of the ship, becomes the body plan of the "construction draught."

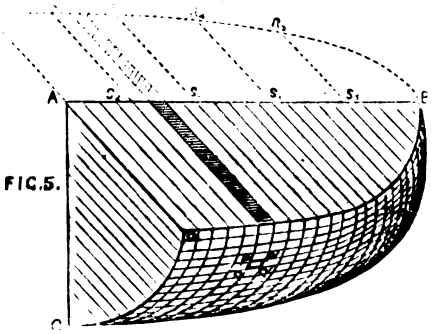

FIG. 5.

an ellipsoid, for instance, of which AB, AD, and AC are the semi-axes, and equal to a, c, and b respectively; and take these as the co-ordinate axes. Then the surface of the ellipsoid is such that all sections of it made by planes perpendicular to the axes are ellipses. Let a number of such planes, which are also parallel to the co-ordinate planes, CDA, DBA, be drawn, at distances δx and δy respectively apart, dividing the solid into a very large number of bars, each having for a base the very small area of $\delta x.\delta y$, in the plane CBA, corresponding to the sheer plan. Let $PP'Q'Q$, be one of these bars, and the distance from P to the plane CBA be equal to z., its distance from $CDA = x$, and from $DBA = y$, then $z.\delta x$, δy is the content of this bar very nearly, and the sum of all these bars will give the contents of the solid when the area $\delta x.\delta y$ is exceedingly small. This sum is represented in the language of the integral calculus by the symbol

$$\iint z.\, dx.dy$$

Now z depends for its value upon its position, or upon the corresponding values of x and y, and by giving x and y any values in the equation to the surface the corresponding value of z is obtained. The equation to the surface of the solid we have taken as an example is

$$z = c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}}$$

and the content of the solid is represented by

$$\iint c\sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}}\,.\,dx.\,dy.$$

When the first integration is performed one of the quantities x or y remains constant (x suppose) and the other (y say) will be variable, consequently the integral taken is that of $z.dy$. The result, when the limits have been taken, is represented by

$$\int \frac{\pi}{4}\cdot\frac{bc}{a^2}\,(a^2 - x^2)\,dx.$$

The quantity $\frac{\pi}{4}\frac{bc}{a^2}(a^2 - x^2)$, is nothing more than the area of the section of the solid made by the plane in which P lies, and which is parallel to ACD at a distance x from it, and by giving x any values between zero and AB we may obtain the areas of the sections of the solid, at any distances from CDA.

Let these be obtained at the distances, zero, AS_2, AS_3, &c., and through these points let dotted lines AR_1, S_2R_2, S_3R_3, &c., be drawn perpendicular to AB on the other side of it in the plane ABD, and the numerical values of the sections set off upon these; and in the same manner as lines are taken to represent forces in mechanics, let AR_1, S_2R_2, &c., just set off, represent the areas of the sections of the solid through the same point: then, if Y be the general value of the ordinate at the distance x from A, $Y.\delta x$ is the elementary area of the superficies, bounded by AB, AR_1, and the curve, the ordinates to which represent the area of the sections of the solid. This small area is shaded in the figure.

Since $\frac{\pi}{4}\frac{bc}{a^2}\left(a^2 - x^2\right)$ is the area of the section of the surface at a distance x from CDA, $\frac{\pi}{4}\frac{bc}{a^2}\left(a^2 - x^2\right)\delta x$ is the content of a slice of the solid made by planes parallel to CDA at a distance of δx apart, as shaded in figure 5, and $\int \frac{\pi}{4}\frac{bc}{a^2}\left(a^2 - x^2\right)dx$ is the representative of the sum of all these.

But since $Y = \frac{\pi}{4}\frac{bc}{a^2}\left(a^2 - x^2\right)$, $\therefore \int Y dx$ must be equal to $\int \frac{\pi}{4}\frac{bc}{a^2}\left(a^2 - x^2\right)dx$ taken between the same limits. If the integration be performed, the content of the solid is obtained in one case and in the other, the curvilinear area* the ordinates to the curve of which are taken to represent the areas of the sections parallel to CDA. The result of the integration is $\frac{1}{6}\pi abc$. The area of the figure AR_1B is therefore numerically the same as the contents of the solid $ABCD$; and the area of any part $R_2R_4S_4S_3$ numerically the same as the contents of the solid intercepted by planes parallel to CDA through the same points S_3, S_4. It is clear therefore that in order to obtain the content of a regular solid by the integral calculus, it is necessary in the first place to obtain the general value of the complete area of the sections parallel to one of the co-ordinate planes, as CDA, and in the second place to do what amounts to finding a curvilinear area, the ordinates to the bounding curve of which represent the areas of the corresponding sections.

If the moment of the solid about one of the co-ordinate planes CDA be required, we see that the moment of the whole would be equal to the sum of the moments of all the bars $z.\delta x.\delta y$, or to the sum of all the quantities $z.x.\delta x.\delta y$, which is represented by the symbol $\iint z.x\, dxdy$.

As before, x will be constant, and the first process gives the same quantity as that obtained in the first operation, multiplied by x;

$$\text{or } \int \frac{\pi}{4}\frac{bc}{a^2}\,(a^2 - x^2).\, x\, dx.$$

The quantity $\frac{\pi}{4}\frac{bc}{a^2}(a^2 - x^2).\, x$ may, as before, be represented by the ordinates to a curve, and the area of the superficies included between the co-ordinate axes and the curve will represent the whole moment of the solid about the plane CDA.

We have above attempted to prove that each step in the process of integration is identical with that of finding a curvilinear area; and that if we represent areas, moments, &c., by ordinates we are really doing the same as the integrator when, step by step, he proceeds until he completes the process of his integration, and obtains rules for measuring cubic contents, the accuracy of which is never doubted. And, as a consequence, the questions of finding the cubic contents of a solid, its moment about any plane, &c., are all reduced to that of finding a curvilinear area.

The reason why such prominence has been given to the above proof is this: many persons seem to doubt the accuracy of a result which has been obtained by representing an area by a line; and the following instance in the mensuration of a square balk of timber, fig. 6, is taken as a case of

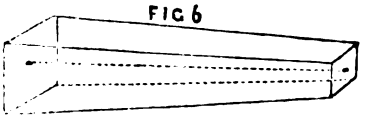

FIG 6

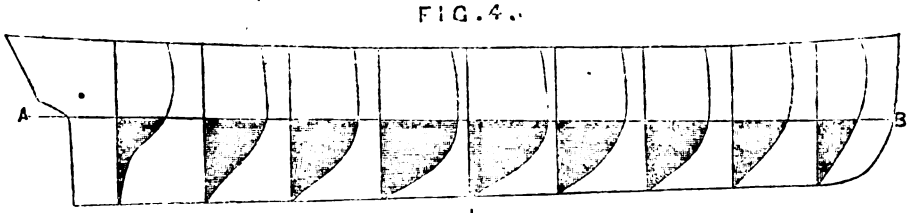

FIG. 4.

Let, then, fig. 4 represent the construction sheer draught of a ship, AB being the line of the load water section, and let the equidistant transverse sections, perpendicular to the sheer plan and load water section, be turned round their lines of intersection with the sheer plan. Now, what we have to do in finding the "displacement" of the ship is, to find the contents of the solid the transverse sections of which are represented by the shaded parts of the figure.

If ships were similar to each other, on knowing the displacement of one, that of any other could readily be found; it would be to the given displacement as the cube of one of its principal dimensions is to the cube of the like dimension of the first ship. Or if the submerged parts of ships were of any regular form, such as a hemisphere, a semi-spheroid, &c., the cubic contents could be obtained from the principal dimensions by the rules of mensuration. The content of a hemisphere of which the diameter is a, is $\frac{2}{3}\pi a^3$,* or, $\frac{1}{6}\pi\, l.\, b.\, d.$ if l, b, and d, represent the length, breadth, and depth respectively of a ship of that form;

that of an oblate spheroid is $\frac{2}{3}\pi a^2 b$ or $\frac{1}{6}\pi.\, l.\, b.\, d.$
that of a prolate spheroid is $\frac{2}{3}\pi ab^2$ or $\frac{1}{6}\pi.\, l.\, b.\, d.$
and that of an ellipsoid $\frac{2}{3}\pi abc$ or $\frac{1}{6}\pi.\, l.\, b.\, d.$

But these rules are obtained by the aid of the Integral Calculus, and as the manner of obtaining such rules will, we think, throw much light on the more general question which we have to do with, we will now endeavour to describe the process, and render ourselves intelligible to those who are without a knowledge of the calculus.

Let $ABCD$, fig. 5, represent any regular solid,

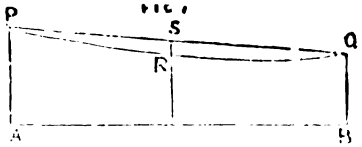
* π *(pi)* is the ratio of the circumference of a circle to its diameter. Its numerical value is 3·1416 nearly.

* *Definition.*—A curvilinear area is the area of a plan figure bounded by a curve and one or more straight lines

Digitized by Google

failure of such a method of proceeding. The length of it is l feet, the area of one end a^2, and the area of the other b^2; the content given in works on mensuration is $(a^2 + ab + b^2)\frac{l}{3}$

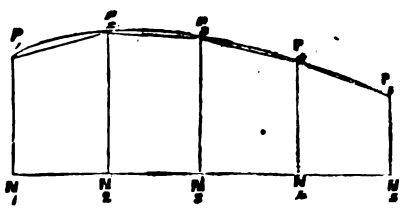
FIG. 6.



Let AB, fig. 7, be equal to l measured by a scale, AP numerically equal to a^2, BQ to b^2; then, say they, as the piece is straight, PQ must be joined by a straight line, and the contents, according to that method, will be $\frac{AP + BQ}{2} . AB = \frac{(a^2 + b^2) \times l}{2}$ Now this is wrong, and for this reason:—the extremities of the ordinates which represent the areas of the cross sections of the piece do not lie in a straight line, PSQ, as has been supposed, but in a curve, PRQ. Let the cross section be obtained at the middle point; the side of square $= \frac{a+b}{2}$ and the area of it $= \left(\frac{a+b}{2}\right)^2 = \frac{a^2 + 2ab + b^2}{4}$ and not $\frac{a^2 + b^2}{2}$ as was supposed.

Now, we shall presently shew that the area of the figure, the three equidistant ordinates of which are a^2, $\frac{a^2 + 2ab + b^2}{4}$, and b^2, and the distance between the ordinates $\frac{l}{2}$, is $(a^2 + ab + b^2)\frac{l}{3}$, exactly the same as that given in text-books on mensuration. We now proceed to the question of finding a cuvilinear area.

FIG. 8.



Let $N_1P_1P_5N_5$, fig. 8 be the figure; and $N_1P_1N_5P_5$ be perpendicular to N_1N_5; divide N_1N_5 into a number of equal parts, and at the points of division draw P_2N_2, P_3N_3 &c, perpendicular to N_1N_5; let m represent the common distance between the ordinates; and $a_1, a_2, a_3, a_4, \ldots$ &c. $\ldots a_n$ the lengths of the respective ordinates, a_n being the length of the last. Now of the nature of the curve joining all the points $P_1P_2P_3$ &c. we know nothing whatever, except that it is what is termed a *fair curve*. As a rough approximation to the area of the figure, if the extremities of the consecutive ordinates be joined by straight lines, we shall have for the area of the figure, the sum of all the trapeziums—neglecting as small the parts outside the straight lines P_1P_2, P_2P_3, &c.

$$\text{Area, } P_1P_2N_2N_1 = \frac{a_1 + a_2}{2} \times m$$

$$\text{,, } P_2P_3N_3N_2 = \frac{a_2 + a_3}{2} \times m$$

$$\text{&c.} \qquad = \text{&c.}$$

$$\text{,, } P_{n-1}P_nN_nN_{n-1} = \frac{a_{n-1} + a_n}{2} \times m$$

sum of all the trapeziums =

$$\left\{\frac{a_1}{2} + (a_2 + a_3 + \text{&c.}) + \frac{a_n}{2}\right\} \times m$$

Whence this rule:—To half the sum of the first and last ordinates add the sum of all the other ordinates; then multiply the sum of these by the common interval, m. This gives a rough approximation to the curvilinear area $P_1P_5N_5N_1$. This is called by writers on naval architecture Rule 1; but it is now rarely made use of, and we should have abstained from giving it but from the fact that no other was used until about the end of the last century.

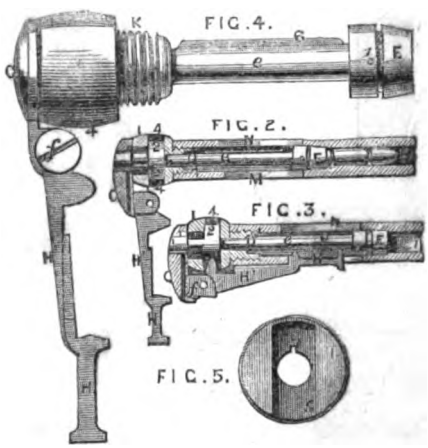
THE NEW BREECH-LOADING CAVALRY RIFLE.

THE Secretary of State having ordered the immediate supply of Terry's Patent Breech-Loading Rifle to several cavalry regiments, a description of the weapon will doubtless be interesting to our readers. Mr. William Terry, the inventor, is a Birmingham gunmaker, and his invention was patented on the 7th April, 1856. The arm is of simple construction, being loaded through an aperture in the side of the breech, in a manner similar to that which was described by Robins, in his "Treatise on Gunnery," more than a century ago, who (as Lieut. Busk remarks) somewhat prophetically said, "perhaps something of this kind would be of all others the most perfect method for the construction of these sorts of barrels." Lieut. Busk does not speak highly of the Terry Rifle, but states, that a carbine on this construction sent to him for trial, "did not load with the same facility as one of Prince's Rifles, nor was its accuracy of fire at all comparable to that of the latter weapon."

The new arm is illustrated in the annexed engravings. Fig. 1 is a side elevation of a complete Terry Fire-arm. Fig. 2 is a longitudinal horizontal section, of part of the barrel of the fire-arm, showing the mode of arranging and actuating the mechanism employed for inserting the cartridge into the barrel, and securely holding it during the discharge. Fig. 3 is a similar section to the last, showing the mechanism in different positions. *A*, is the stock of the fire-arm; *B*, the barrel; *C*, an ordinary percussion lock; *D*, the breech. The construction of this part of the fire-arm and the mechanism connected therewith forms the principal part of Mr. Terry's improvements. *E* is a sliding piston, the rod *e* whereof is securely fixed into a piece of metal *G*, to which is also hinged at *f* a lever *H*, *H'*, employed for the purpose hereafter mentioned. *I* is a piece of metal passing over the piston rod *e*, and connected to the breech end of the barrel by a screw *K*, formed in the end of the barrel and around the piece *I*. The piston *E*, Fig. 4, is formed slightly taper and solid, and is securely connected to the piston rod *e* by a pin at 1; and the diameter or calibre of the bore of the barrel at the breech end thereof is somewhat larger than the other part of the barrel, and is made conical to receive the taper part of the piston, which should fit, as far as practicable, air-tight therein. The piston rod *e* has two lugs or projections, 2, 3, formed thereon, which take into slots or openings, 4, 4, formed opposite to each other in the piece *I*, as at Fig. 2; an opening, 5, is formed in the piece *I*, as at Fig. 5, to enable the parts, 2, 3, to be inserted into that piece. One side of each of the slots, 4, 4, as also of the lugs, 2, 3, is formed inclined or sloping in opposite directions, so that when the lugs, 2, 3, are moved in said slots the piston *E* shall be forcibly pressed into its seat and held there. In order to effect the partial turning round of the lugs, 2, 3, as lastly stated, the feather 6 in the rod *e* is free of the groove 7 in the piece *I*, in which the feather slides for drawing back the piston, to allow the cartridge to be introduced into the breech through the opening *M* formed in the side, the said opening being nearly entirely closed by the outer end of the lever *H*, which fits therein, as at Figs. 1 and 3. There is a tempered steel spring attached to the piece *G*, and employed for securely keeping the lever *H*, *H'*, in the opening *M* during the discharge of the contents of the fire-arm. The upper and under sides of the part *H'* of the lever *H* are sufficiently bevilled inwards to enable them to be readily gripped by the finger and thumb for withdrawing the lever and pulling back the piston when it is desired to introduce a fresh cartridge at each discharge of the fire arm. *N* is a slot or opening formed in the breech for the escape of dirt, &c.; and *O* is a recess, containing cotton saturated with oil or other lubricating substance, so that at each discharge of the fire-arm the piston rod is both lubricated and cleansed in a simple and efficient manner. As regards the construction of the piston *E*, in order to provide means for compensating for the wear of the piston, Mr. Terry proposes, if necessary, to construct the piston in two parts, in such manner as to compensate for any wear, without having to substitute an entirely new piston.

FIG. 1.

FIG. 4.



The military correspondent of the *Times*, speaking of the Terry Rifle says:—"The peculiar advantage of this weapon is to make one man equal to ten; the carbine may be loaded with facility at the time of a horse being at full gallop, because neither biting the cartridge nor a ramrod is required, and there is no risk of blowing off the hand while loading. The Small Arm Committee have submitted the carbine to the soverest tests, making a most favourable report on its peculiar advantages, and hence its adoption in the army. Only some few months ago Terry's Rifle was subjected to a test by Captain Richard Hewlett, of the Excellency gunnery ship, and 1,800 rounds were fired without the carbine requiring to be cleaned, or missing fire; the same carbine was tested on Southsea-common by order of the Lieutenant-Governor Major-General the Hon. Sir James York Scarlett, and 25 rounds were fired at 300 yards' range from the butt; and the General himself made a centre hit. An officer on the ground, one of the instructors of musketry, then took the instrument and struck the target afloat twice out of three times, at a distance of 1,050 yards; yet the barrel is but 30 inches in length."

A SLAVE'S INVENTION.—We read in a letter from New York:—"There is a curious case shortly to come before the Federal Courts. A negro slave invented a machine, and applied for a patent. It was denied him, as a matter of course. His master now insists on its being granted to him, inasmuch as he owns the inventor he owns the invention. But he is not the inventor, the patent office hesitates, and he talks of a mandamus. What curious legal complications are raised by chattels having faculties."

SCOTT'S PATENT APPARATUS FOR DRESSING, SEPARATING, AND CLEANING SEEDS.

FIG. 5.

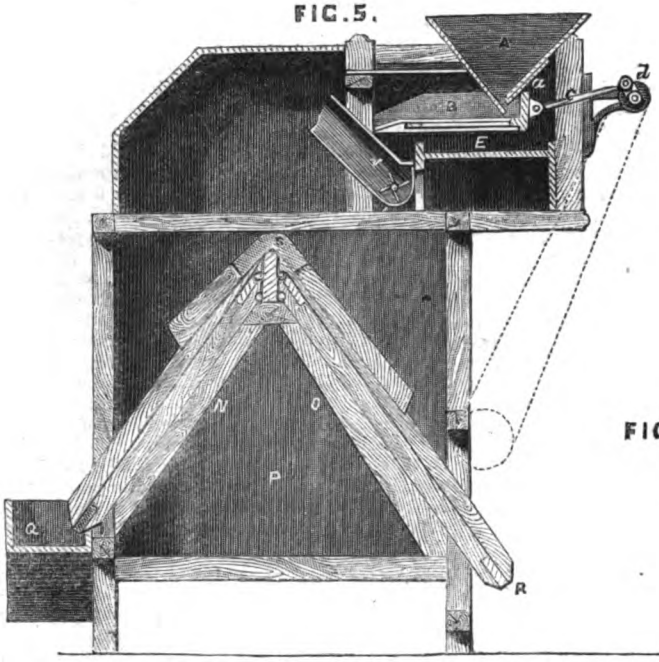

FIG. 6.

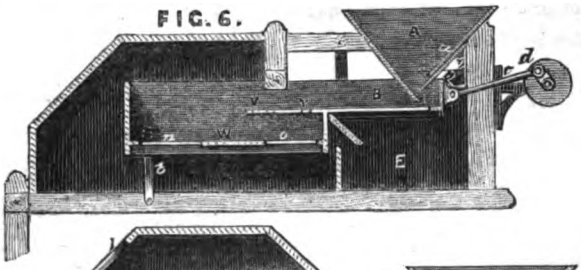

FIG. 1.

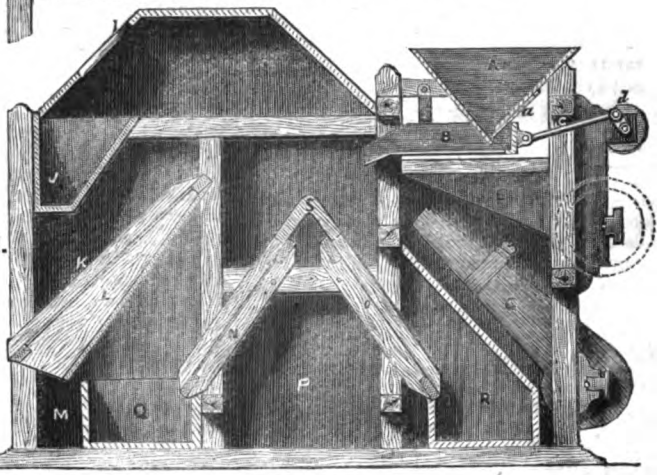

FIG. 7.

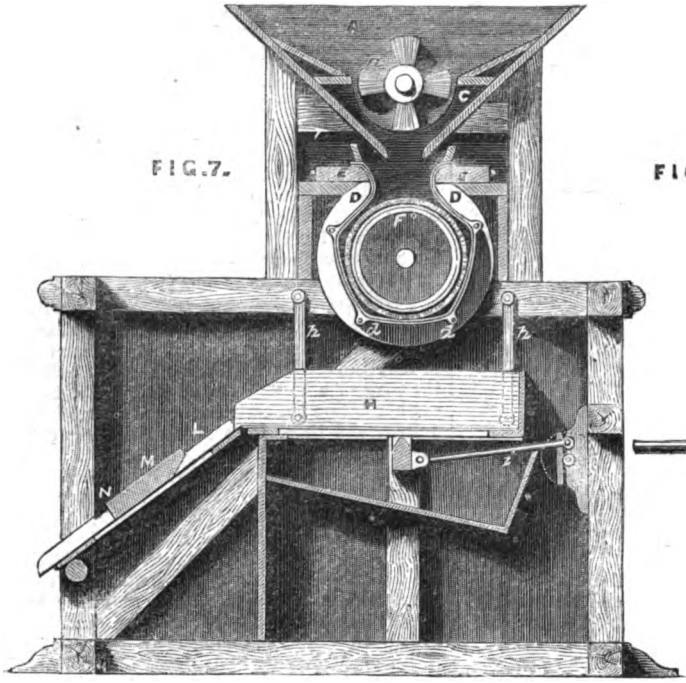

FIG. 8.

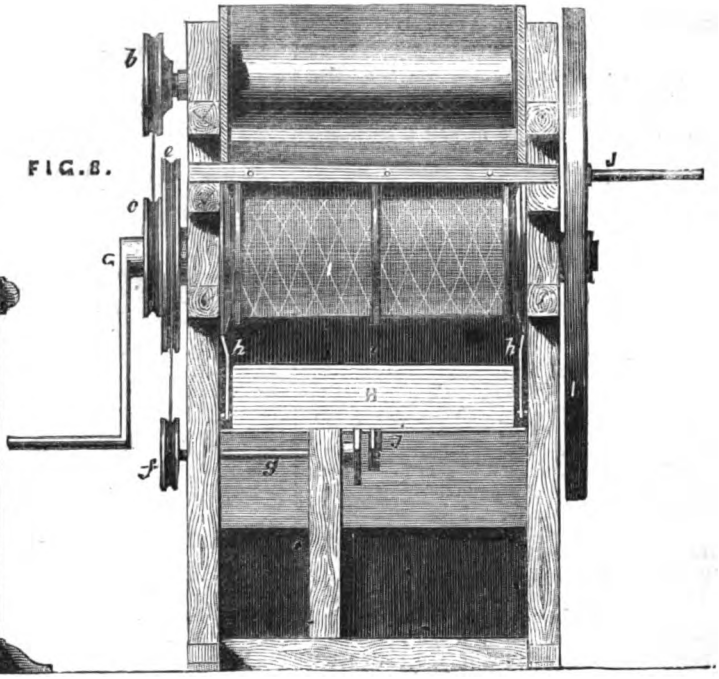


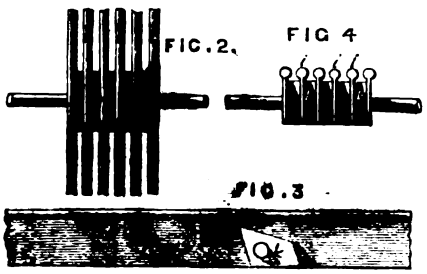
SCOTT'S PATENT APPARATUS FOR DRESSING, SEPARATING, AND CLEANING SEEDS.

OUR attention having been attracted by the specification of a patent granted to Mr. Thos. Scott, of Drummond-street, Euston-square, in which a very valuable set of machines for dressing, separating, and cleaning seeds is described, we now lay the same before our readers. These machines appear to have been devised with an accurate knowledge of, and a careful regard to the evils which they are intended to remove—evils of very great importance to the agriculturalist. As the specification of Mr. Scott's patent is very voluminous, we must condense it as much as possible, and print it in small type, in order to economise space. The following is substantially what is stated in that document.

Carrot seeds, the seeds of some sorts of weeds, and other seeds have beards, tails, down, husks, or hulls. Grass seed is often mixed with the seeds of weeds having horns or tails, and also with round or other shaped seeds. The patentee causes the grass seed and its impurities to descend from a hopper on to a reciprocating sieve with longitudinal spaces, from which it falls on sloping sieves with longitudinal spaces. The grass seed slides down and off the end of the sieve, while the tailed or horned seeds fall with a spiral motion, or in such a position as to pass through the longitudinal spaces of the sieve. The first reciprocating sieve also separates a portion of these seeds, and of the small round seeds which may have been mixed with the grass seed. He sometimes projects the seeds by centrifugal or other force, and allows them to fall upon the aforesaid sieve or grating; or, in some cases, the seeds being projected to different distances, according to their weight or form, are received in different receptacles. For cleaning or dressing carrot seed and similar seeds, so as to remove the tails, beards, husks, or hulls from them, he employs cylinders, or cones covered with wire cord metallic brushes, perforated metal, or other suitable rough surface, which is enclosed in a wire gauze casing. Or the wire cords or brushes may be arranged on a disc revolving in proximity to a fixed sieve. The seed is introduced between the two surfaces, and the tails, beards, or husks are rubbed off, and pass through the gauze. The carrot seed may pass out at the end or sides, or it may pass through with the detached tails or beards, and be afterwards separated by sifting, winnowing, or otherwise. The wire gauze casing may fit the wire cord surface, or may touch it at certain points, or may have cavities at intervals, and be adjusted by screws or other means. He sometimes applies a gentle heat for drying the seed by means of gas burners, or otherwise. The last portions of the tails or down may be removed by sieves with rubbers, which rub them through while the seed passes off at the end. This rubbing apparatus may also be used in combination with a winnowing machine, or with the machines before-mentioned.

Fig. 1 of the accompanying engravings is a longitudinal section of one of Mr. Scott's machines for dressing grass seed. *A* is a hopper with a slide *a* for adjusting the aperture at the bottom. *B* is a vibrating sieve suspended by links, and driven backwards and forwards by a connecting rod *c*, and a crank *d*, which is driven by a band passing round a pulley on the crank shaft, and another pulley on the main shaft, which may be turned by hand by means of a winch, or by power. *E* is a box which receives the dust

Digitized by Google



and dirt, and any small seeds which are shaken through the sieve *B*. The main shaft carries another pulley, round which passes a band which drives a pulley on the spindle of a blowing fan, or winnower *F*. The air from the fan *F* is conducted up a spout or trunk *G*, with an adjustable opening, and is directed upon the seed falling from the sieve *B*. *I* is an aperture for the escape of the air and chaff, or light particles. *J* is a box or pocket. *K* is a sieve which may be fixed, or made capable of adjustment to various angles. *L* is a tray or box under the sieve *K*, which directs the matters passing through this sieve into the space *M*. *N* and *O*, are two inclined sieves with a space *P* under them to receive anything which passes through them, and with two boxes, *Q R*, to receive all that passes off the top of the sieves. *S* is a sort of cap or saddle to prevent any seeds from falling between the top of the sieves *N O*. These sieves may be fixed, or may be capable of adjustment to various angles. The sieves *N O K* and *B* are constructed with longitudinal bars, as shown in Figs. 2, 3, and 4; *i i i* are longitudinal bars, having a bead along the top edge, and made thinner beneath, so that anything passing through the top may escape freely at the bottom. The mode of making these bars may be varied. They are kept at the proper distance apart by small pieces of metal, *k k*, and are held together by a rod passing through them, or otherwise. They may be made adjustable. The pieces *k k* are angular at top, and kept a little below the bead, so as not to obstruct the passage of the seeds, like the cross wires of an ordinary sieve. Moreover the bars *i i* are so strong and stiff that few transverse supports are required. The bars are so close that good grass seed cannot pass through. The action of this machine is as follows:—The seed to be cleaned is thrown into the hopper *A*, and allowed to fall on the sieve *B*, which is kept in rapid vibration by the winch. The dust, small particles of dirt, round seeds smaller than grass seed, and some of the immature and useless grass seed pass through the sieve *B* into the box *E*. The tailed or horned seeds of weeds, although smaller or thinner than grass seed, lie upon the sieve, very few of them passing through. They are carried forward with the grass seed by the vibration of the sieve, and fall over the end into the blast of air from the fan. The lighter downy portions are thus blown out at the opening *I*; while the heavier fall into the box *J*, and the still heavier fall on to the sieve *K*. The good grass seed and the heavier horned or tailed seeds of weeds fall upon the sieves *N O*. The seeds are so shaken and separated by falling from the vibrating sieve through the blast of air, that for the most part each seed falls separately through the air. The grass seeds slide down the sieves into the boxes *Q R*. The horned or tailed seeds, on the contrary, fall like little darts or arrows, frequently acquiring a revolving or spiral motion, and pass between the longitudinal bars into the space *P*. A similar effect takes place with the lighter seeds which fall on the sieve *K*, and a portion of rather lighter grass seed runs off the lower end of this sieve. If any grass seed should be found in the box *J*, it will be of inferior quality. The heaviest clean grass seed is received in the box *R*, and the next heaviest in the box *Q*, and a rather lighter seed runs off the sieve *K*. Instead of the three sieves *K N O*, more may be employed, to separate the grass seed into a greater number of qualities.

The above machine admits of several modifications:—Thus a plain vibrating table, or tray, may be used in lieu of the vibrating sieve B, or a revolving fan may be employed for scattering the seed, and throwing it on the sieves *N* and *O*. The winnowing fan may also be dispensed with. Fig. 5 is a longitudinal section of a machine in which the seed is thrown into the air by centrifugal force. *A* is the hopper, with its slide *a*. *B* is the vibrating sieve, driven by a connecting rod *c*, and crank *d*, which is driven by a band passing round a pulley on the crank shaft, and another pulley on the main shaft, which may be turned by hand or otherwise. *E* is a box, which receives the dust and dirt, and any small seeds which are shaken through the seive *B*. The crank shaft carries another pulley, round which passes a band which drives a pulley on the spindle of a centrifugal beater or fan, placed in a case or spout, *v*. *N* and *O* are the two inclined sieves, with longitudinal bars as before, and *P* is the space between them; and *Q* and *R* are the boxes for the reception of the clean seed. *S* is the saddle piece on the sieves *N O*. The seed descends from the hopper *A*, on to the vibrating sieve *B*, and drops from the end of this sieve into the case *U*, and is then thrown out of the spout by the rapid revolution of the centrifugal beater. It falls on the sieves *N O*, and the grass seed slides off the sieve at *Q* and *R*, while the horned or tailed ends of weeds pass through the sieves into the space *P*. The arms or blades of the beater may be of different lengths, or placed at different angles, so as to throw the seeds to different distances. A revolving disc may also be used to project the seed on to the sieves.

Fig. 6 is a section of another arrangement of apparatus which may be substituted for the centrifugal beater, and the upper part of the apparatus shown in Fig. 5. *A* is the hopper, with its slide *a*. *B* is a vibrating sieve, driven by a connecting rod *c*, and crank *d*. *V* is a table, or tray, and *W* is another table, or tray, with two openings *n o*, covered by coarse sieves or wire netting. These trays are mounted in the same frame as the sieve *B*, and vibrate with it. The seed is thus shaken over the end of the tray *V*, and falls on the tray *W*, and thence through the openings *n o*, on to the sieves *N O*, shown in Fig. 5. If too much of the seed should pass through the opening *n*, a hole *v* may be made in the tray *V*, so as to equalise the quantity falling on each sieve. Instead of the crank motion, the vibrating sieves and trays may receive a jogging motion, by being moved in one direction by a cam or tappet, and allowed to return and strike against a stop by their own weight or by springs. Fig. 7 is a transverse vertical section of a machine for cleaning carrot seed, constructed according to Mr. Scott's invention. Fig. 8 is a side view partly in section. *A* is a feed hopper, in which is a revolving drum *B*, carrying four brushes *a a*, which run in contact, or in close proximity, to a semi-cylindrical sieve or grating *C*, with meshes or openings large enough to allow of the passage of the seeds. The seed falls into a case *D*, which consists of wire gauze supported by a coarse wire netting, which is itself supported by bars or frames, jointed together at *d d*. These frames are supported at the top by two blocks *H E*, adjusted by screws, and at the bottom by a lever or wedge (not shown), by adjusting which, and the blocks *E E*, the distance of the wire gauze case from the drum *F* is regulated. *F* is a drum covered with wire card similar to that employed for carding cotton, &c. By the revolution of the drum *F*, the seeds are forcibly rubbed at the parts where the wire gauze approaches closest to the drum, and they are rolled about in the recesses opposite the joints *d*, and are again carried on and rubbed about until the horns or tails are detached and reduced to powder or dust, and pass with the seeds through the wire gauze, falling on the vibrating sieve *H*. This sieve is suspended by links *h h*, and is driven backwards and forwards by a connecting rod *i*, and crank *j*, on the spindle *g*, which carries a pully *f*, driven by a band from a palley *e*, on the shaft of the drum *F*. Another pulley *c* on the same shaft, drives a pulley *b* on the spindle of the brush drum *B*. The shaft *G* may carry a fly wheel *I*, and may be driven by hand winches *J K*, or otherwise. The horns and tails being reduced to dust, pass through the vibrating sieve *H* into the space beneath, while the clean carrot seed is shaken out at the end of the sieve and falls on an inclined sieve, which is jointed to the sieve *H* at the upper end, and rests upon a roller or bar at the lower end. *M* is a rubber, formed of a flat piece of wood, covered with leather or plush, and bevilled or curved at its upper end. This rubber lies on the sieve *L*, being confined by a lodge at each side of the sieve, and a bar or stop *N* on the frame of the machine. As the sieve *L* moves backwards and forwards, the seeds pass under the rubber *M*, which rubs off and through the sieve any slight portions of the horns which may remain on the seeds, these finally passing off in a clean state from the lower end of the sieve. This machine, like the others, admits of several modifications, some of which are described in the patentee's specification. The machines described above particularly refer to the dressing of grass and carrot seed, but they may be used for clover and many other seeds, the width of the spaces in the sieves and wire gauze being varied according to the size or nature of the seeds operated upon.

It is not our intention, either here or in future cases, to urge agriculturalists to the use of newly-invented apparatuses. Our business is mainly to *describe* them, and thus afford the reader the means of judging for himself. We may, however, state that there seems to be no room for doubting either the utility of the machines described above, or the urgent necessity for them which exists. In reference to the grass-seed separator, the patentee, in his prospectus, speaking of Italian rye-grass, says:

> Very few samples of the seed of these valuable plants are free from admixture with that of the most noxious and—in its eradication from the land—expensive weeds known to the farmer, viz., 'couch' or 'twitch' grass, and the great difficulty and expense attendant on even its *partial* removal is well known to all in the agricultural seed trade. It is to the presence of the seeds of this *pest* that the observation now becoming so general amongst farmers is attributable—that, when they have sown rye-grass with clover, they find, on ploughing for the succeeding wheat crop, that the land is replete with a luxuriant braird of healthy 'twitch,' although in the preceding fallow it had been thoroughly cleaned. The detection of the seeds of couch-grass amongst those of rye-grass, in such quantity as to produce the effect above referred to, is, by a mere superficial inspection, by no means easy; and hence it is now no uncommon thing to hear intelligent farmers allege that to sow rye-grass and to sow couch is synonymous. It is needless to say that nothing could be more erroneous than this conclusion, by which two of the most valuable grasses in cultivation are confounded with one of the most objectionable and expensive weeds.

It will be the fault of farmers themselves if, after the production of Mr. Scott's machines, they continue to propagate "twitch," for while it may not be expedient in all cases to have a machine for their own separate use (although we see that the patentee has contrived one of somewhat smaller capacity, which is within the reach of almost every occupier of land), they have only to bargain with the local seedsman, and insist on the condition that their rye-grass shall be entirely free from "twitch," "couch," "hair," or "spear" grass seed. The seedsman cannot now urge in excuse the impossibility of extracting these noxious seeds.

We proposed adding a remark or two on the importance of the purification of carrot seed, and of the fitness of the above machines for effecting it; but our space is gone, and we must, therefore, refer inquirers to the patentee for further information.

THE UNITED STATES' NAVY.

THE Secretary of the United States' Navy says that since his last annual report it became necessary to charter a number of vessels. As these vessels would be useful, he recommends their purchase. The sum required for six would be 244,000 dols., of which 94,800 dols. must be paid for the use of them for a period of six months, and a porportionate sum for a longer time if no purchase be made. The five steam sloops-of-war authorised by the Act of 1857 will soon be completed. The seven screw sloops-of-war, under the Act of 1858, are in a state of great forwardness. All experience evidences a necessity for an increase of the navy. Twenty effective vessels of smaller class can be built and kept at sea for what it would cost to build and keep at sea four or five vessels of a larger class. Let Congress increase the number of heavy-armed vessels of light draught until we can frequently display our flag at every point where American interests may need protection. The addition of at least ten more vessels of that description is not only a necessary measure, but will be found to be as efficient as any that can be desired, requiring so small an expenditure of the public money. In the construction of the steam-ships authorised by Acts of Congress, it has been the aim of the Department to combine speed and power with strength in the highest practical degree for vessels of their class. Accordingly models have been selected with particular reference to their adaptation to the greatest attainable speed, and contractors for the engines and machinery under the Act of last session have been required to guarantee the result of their plans, by stipulating the number of revolutions to be performed in a given space of time. In placing an estimate upon the value of high speed, the importance of it has not been too highly appreciated. Of two war vessels—the equals of each other in every other respect—the one which has the greatest speed has a decisive advantage over the other, and in a contest is most sure to win. The time has gone by when steam can be regarded in any other light than as the principal motive power on the water for warlike purposes. It is impossible any longer to regard the unsteady and uncertain power of the wind as anything more than an auxiliary power, subordinate to that of steam. In the construction of a war vessel everything connected with it has ultimate reference to a single point, the use of the gun; by which alone, as the means or instrument of power, important results are to be accomplished. To place it in the presence of the enemy, or beyond his reach in the shortest possible time, and to use it with the greatest possible effect, is the great object to be sought for in the construction of a navy or the maintenance of its auxiliary establishments. It is to attain this object that the skill of the departments of ordnance, of construction, and of engineering is taxed to the utmost. They will not rest satisfied until they have given to the service the fastest war ship which skill and science can produce.

RIFLE SHOT.—There are cases in which the expanding principle of lead, or other elastic matter, is not required in rifle shot. For instance, it is not required for breech-loading rifles, neither is it required when shot have projections on them to fit accurately into the grooves of a rifle when loading at the muzzle, nor with the rifle shot of the late gallant and intelligent officer, General John Jacob. It is not required in shot adapted to the two-groove elliptic bore rifle, and for this latter the shot may be made of a mixture of lead and tin, which is desirable for shooting lions, tigers, and other strong wild animals, or wherever great penetration is required.—J. NORTON.

MR. SCOTT RUSSELL'S PATENT THREE CYLINDER ENGINES.

FIG. 1.

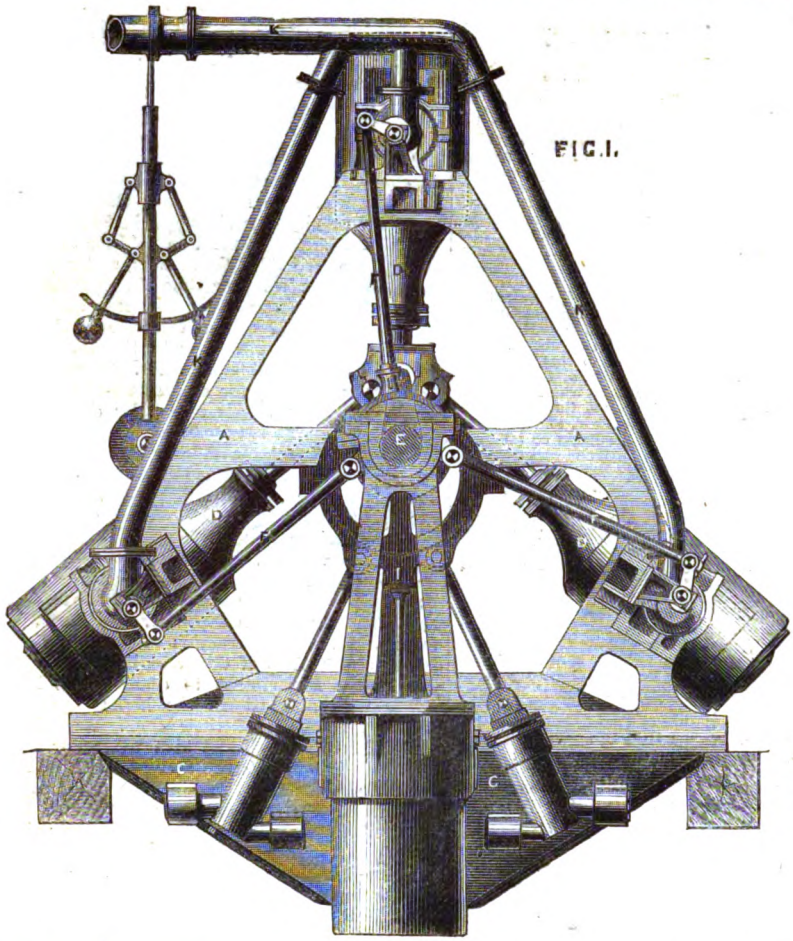

FIG. 2

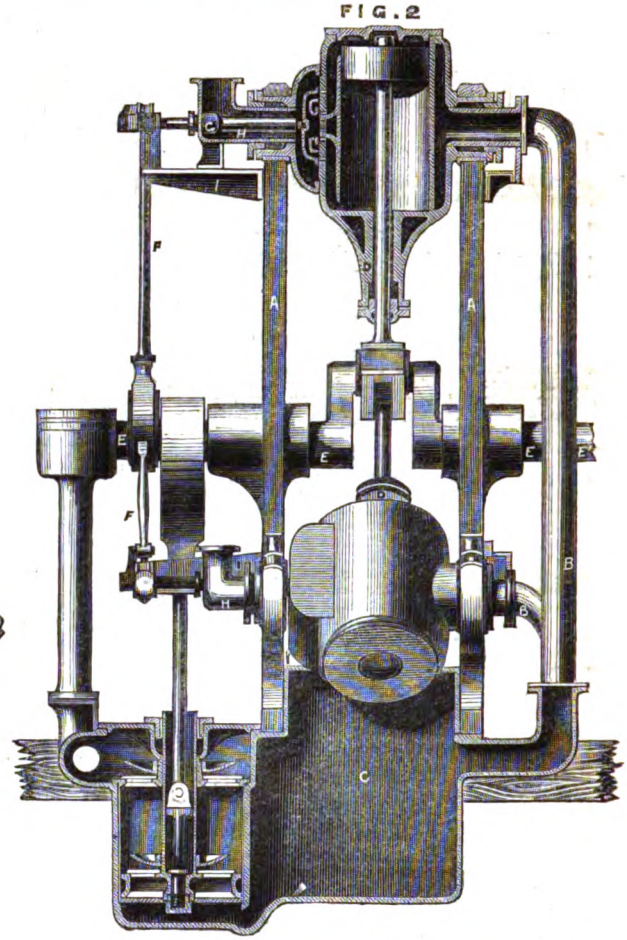

MR. SCOTT RUSSELL'S PATENT THREE-CYLINDER ENGINES.

THE three-cylinder oscillating engines lately fitted by Mr. J. Scott Russell in the exquisite light draught yacht built by him for El Hami Pasha, deservedly excited much attention. The extreme smoothness of their working, evidenced by the almost entire absence of tremor in the vessel when under steam, was most remarkable, and Mr. Russell has found that a much better result, in so far as indicated horse-power is concerned, is obtained from the three-cylinder engine than from any two-cylinder engine he has ever had in use. The form of engine, although patented some years since by Mr. Russell, has not, we believe, been extensively applied until lately. Now, however, it is to be introduced into a light draught steamer building on the Danube; in another built for navigating the shallow rivers of India (a vessel now lying in the Thames at Millwall), and in other vessels, as well as in the Turkish yacht before-mentioned. Several new engines of the same construction are also in course of manufacture at Mr. Scott Russell's works. As an example of this form of construction, we have, however, selected for illustration, not a marine engine, but a fixed engine, which has been erected to drive a portion of the machinery at those works. Fig. 1 of the annexed engravings is a front elevation of it; fig. 2 is a side view partly in section. The engine is in this case supported by a cast-iron frame, *A*; but for marine purposes the frame is sometimes forged in a single piece, and sometimes formed of plate and angle-iron, suitably arranged and riveted, forming a very light but strong combination. The three oscillating cylinders are supported in the positions shown, the piston-rod of all three coming to the same crank-pin. All the cylinders are jacketed, being cast with an external cylinder or casing for the purpose; the escaping steam keeps the inner cylinder hot. All the cylinders condense through pipes, *B*, into one condenser, *C*, placed below the engine. The cylinders are each cast with long necks, *D*, which act as guides, and improve the steadiness of the engine. The valves are worked by a single eccentric, on the main shaft, *E*, by means of rods, *F*. The valve-spindles pass through long stuffing-boxes, *G*, in the hollow trunnions, *H*, which are also the steam induction-pipes, leading from the steam-pipe, *K*, proceeding from the boiler. The outer extremities of the valve-spindles are supported by brackets, *I*, projecting from the frame, *A*. The arrangement and action of the air-pump, feed-pump, &c., will be understood upon inspection of the engravings. The power is taken from the engine by means of a large bevil wheel (not shown) on the extremity, *E'*, of the main-shaft, *E*. We may remark that the third cylinder is sometimes placed below and the two side-cylinders above the shaft. Mr. Russell has been materially aided in bringing this form of engine to its present perfection by Mr. Dickson, the able and experienced manager of the engineering department of the works at Millwall.

OBSERVATORY IN ALGERIA.—An Astronomical Observatory has recently been established near Algiers by the French Government. Besides making astronomical observations, for which the climate is particularly favourable, it is intended to register the meteorology of the district. The observatory will be under the superintendence of Professor Simon, of the Government Lyceum at Algiers; and M. Bulard, who has been furnished with a powerful telescope, will have the charge of the astronomical observations.

TINDALL'S PATENT STREET-SWEEPING MACHINE.

IN the present age, when men are more than ever bending their powers to the development of something better and more ingenious than their predecessors in almost every mechanical department, it is remarkable that no efficient machine has been introduced to supersede the old and degrading system of hand street-cleansing. Attempts have, it is true, been made to accomplish so desirable a result; but, from the expensive, heavy, and inefficient performances of the machinery used, they have proved abortive, and instead of conferring any positive advantage, have rather been retrograde, and consequently abandoned. The simple fact that such attempts have been made, and the machines experimented with officially, is sufficient evidence, however, that our municipal bodies and street contractors are not insensible to the disadvantages of hand street-cleansing, or opposed to its abolition. There is, perhaps, hardly any occupation which could be named which is more unsuitable for manual labour, or which renders the use of machinery more desirable than that of street cleansing. To cleanse *all* the streets in a town is indispensable. To neglect any is a serious omission, fraught with results far more pernicious to the moral and sanitary well-being of its occupants than is, perhaps, often contemplated. But such neglect of necessity forms part of the present partial and inefficient mode of operation. It is not our present intention to enter minutely into the details of the inconveniences and annoyances of the present plan. Of these, most people who are under the daily necessity of traversing our streets have sufficiently disagreeable proof and reminiscences. Our object is rather to direct attention to the accompanying engraving of a newly-invented machine, just patented by

Digitized by Google

TINDALL'S PATENT STREET-SWEEPING MACHINE.

FIG. 1.

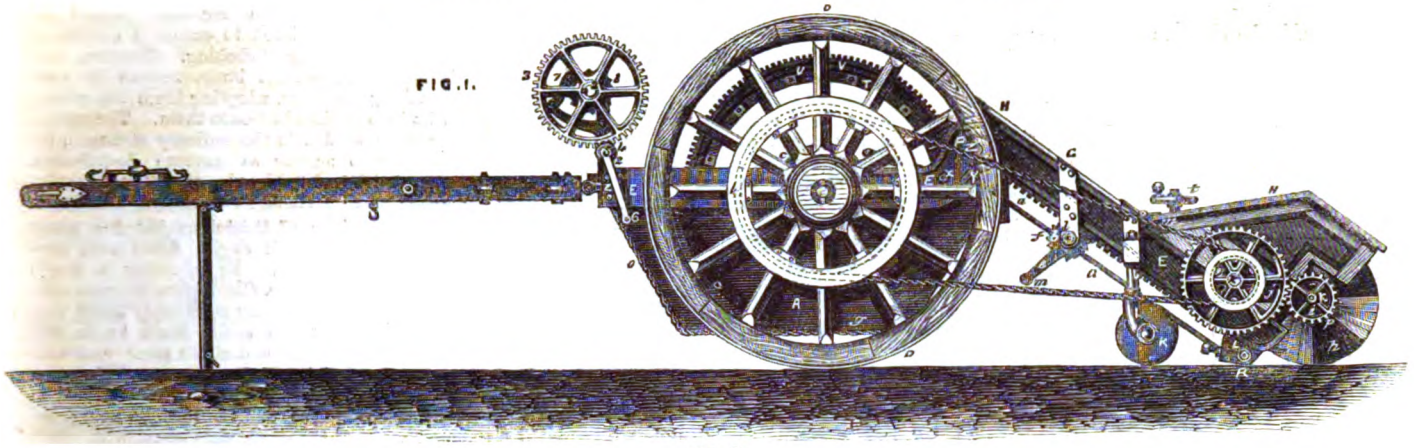

FIG. 2.

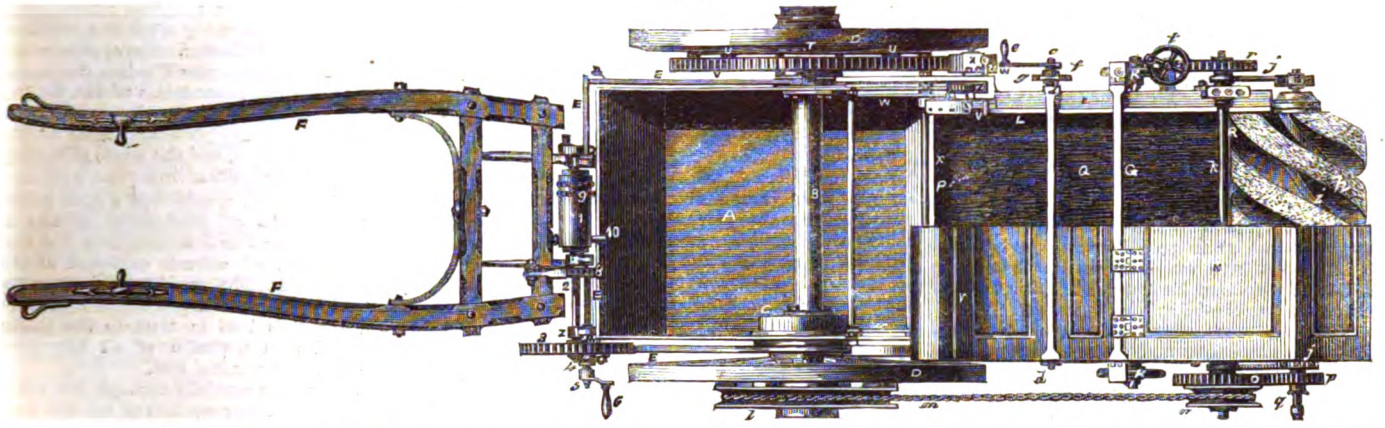

Mr. Lorenzo Tindall, of the Sherwood Iron Works, Mansfield. The arrangements of the machinery are exceedingly simple, and, we think, eminently adapted for the purpose. We understand it has been thoroughly tested, both on wet and dry material, and has proved highly successful. Its manifest utility, combined with the low cost at which Mr. Tindall proposes to manufacture it (not much more than that of an ordinary waggon) will no doubt soon cause it to be introduced into every town where economy and cleanliness are considered desirable. At any rate, we have a high opinion of its merits, and hope to see it largely adopted.

Fig 1. of the annexed engravings is a side elevation of the improved machine, and fig. 2 a plan of the same. The body of the machine which forms a receptacle *A*, in which the mud or dirt is deposited is of a trough-like form, and, by preference, of wrought iron. Across it extends a tubular shaft *B*, the flanges of which are bolted on one side to the trough, and on the other to a box or recess *C*, made to receive the nave of the contiguous bearing wheel. The axles of the bearing wheels *D* pass through the tubular shaft *B*, and through the rectangular framing *E*, which encompasses the upper part of the receiver *A*. The front portion of this framing is of wrought iron, and to the transverse piece the horse shafts *F* are attached. The back portion of the framing *E* is curved upwards at the rear-end of the receiver *A*, and thence descends, forming an incline. The inclined portion of the framing *E* is strengthened by transverse tie pieces *G*, and the open metal frame is covered in by the wooden casing *H*; the lower part of this casing extends upwards to allow room for the brush beneath, and it is hinged at the centre to afford access to the interior. Two adjustable pendent brackets *I* are bolted to the opposite sides of the framing *E*; these brackets may be lenghtened or shortened by adjusting the number of washers at the part *J*. Each of the brackets *I* carries at its lower extremity a stud, on which are carried the wheels *K*, which serve to support the framing *E* at the proper height from the ground, the distance being regulated by altering the length of the brackets. Within the inclined portion of the framing *E* is fitted a secondary frame *L*, of sheet iron, strengthened by transverse rods and diagonal stays *M*. The framing *E* has along each of its inner sides a projecting piece of angle iron *N*, upon the upper edge of which the rollers *O* move; these rollers are carried in brackets that are attached to the sides of the moveable frame *L*. The stationary framing *E*, and the moveable frame *L*, are fitted together so as to prevent as much as may be possible the access of dust and dirt to the rollers *O*. A roller *P*, which extends across the framing *L*, is fitted at its upper part; this roller derives its motion from the "off side" driving or bearing wheel *D*, as will be presently described. An endless belt or sheet of thick matting *Q* passes round the roller *P*; this endless belt serves to carry up the mud or dust into the receiver *A*; it is, by preference, made of cocoa-nut fibre, closely woven for the purpose. The endless belt *Q* is strained round a roller *R* arranged at the lower part of the frame *L*; this roller *R* is smaller in diameter than the upper roller, and its bearings are carried in a slot made in each of the side pieces of the frame *L*. By means of the screws *S* the roller *R* may be moved outwards to the extremities of the slots in the side pieces of the frame *L*; this adjustable action affords the means of regulating the tension of the endless belt *Q* as required. An upward traversing motion is communicated to the carrying belt *Q* from the "off side" wheel *D*. This wheel has a metal ring *T* attached to the spokes; to the face of this ring are bolted the brackets *U*, which form a part of or are secured to the toothed wheel *V*; this wheel *V* gears with an intermediate wheel *W*, the spindle of which is carried in a bracket *X* that is bolted to the framing E, and in a downwardly projecting part of the framing. The shaft of the intermediate wheel *W* also carries a pinion *Y*, which gives motion to the pinion *Z* on the spindle of the roller *P*. When the machine is drawn along the ground the gearing causes the carrying belt *Q* to traverse round the rollers *P* and *R*, and any matters deposited on the upper surface of the belt are carried over the upper roller, and deposited in the trough or receiver *A*; the frame *L* is provided with an arrangement for raising it clear of the ground, to admit of the roller *R* passing over any obstruction. At each side of the frame *L*, on its under side, is a rack *a*, in gear with which are two pinions *b* that are fast to a shaft *c*, carried in the pendant brackets *d*. The shaft *c* is put in motion by the winch handle *e*, behind which is fitted the rachet wheel *f*, into the teeth of which the pawl *g*, which is carried on a stud projecting from the framing *E*, falls. Upon turning the handle *e* the frame *L*, with the carrying belt *Q* and its rollers, traverse upwards over the rear end of the receiver *A*, so as to lift the lower end of the frame clear of any obstruction. The mud or dust is swept on to the carrying belt *Q*, by means of the rotatory brush *h*, which consists of a wooden drum *i*, filled with pieces of split cane or wood *h*, arranged helically, as shown. The journals of the drum *i* are carried in bearings, which are fitted in the free extremities of the arms *j*, the other ends of these arms being fast to the horizontal shaft *k*; this shaft *k* works in pedestal bearings that are bolted to the upper face of the framing *E*. Motion is imparted to the rotatory brush *h* from the "near side" wheel *D*, the nave of which is sunk in the recess *C*; the wheel is thus arranged to admit of the brush *h* sweeping up to the curb of the street. To the spokes of the "near" wheel *D* is bolted the spiked pulley *l*, round the grooved periphery of which is passed the endless chain *m*, through the links of which the spikes of the pulley *l* pass as the wheel *D* rotates. The chain *m* is also passed round a spiked pulley *n*, which is cast in one with the wheel *o*, and runs loosely upon the end of the shaft *k*. The wheel *o* gears with the pinion *p* on the spindle of the drum *i*, and thus causes the brush to rotate when the machine is put in motion. The spindle of the drum *i* is made with a feather *q* to admit of the pinion *p* being thrown out of gear when the brush is not required to be in use. The pinion *p* is held fast on the spindle by a key. When the pinion is taken out of gear with the wheel *o*, the key is taken out, the pinion slipped along the spindle and the key put in on the inner face of the pinion. The machine is also provided with an arrangement for adjusting the height of the brush *h* from the ground. On the extremity of the shaft *k*, which projects out from the "off side" of the machine, is keyed a segmental wheel *r*, that is in gear with the vertical worm *s*, which is carried in a bracket projecting from the stationary framing *E*. The spindle of the worm *s* extends upwards above the cover and terminates in a hand-wheel *t*; by turning this hand-wheel *t*, it raises or depresses the segmental wheel *r*, and this being fast to the shaft *k*, which carries the arms *j*, the brush *h* is thereby raised from the ground or lowered, as the material of which it is made wears away. To prevent the worm *s* from turning when not required, a pin is passed through a hole made in the spindle, the extremity of which is fixed in one of a series of notches made in the boss, through which the spindle passes, so that it is kept exactly in the position required. At the upper part of the inclined portion of the framing *E*, is a bolt *u* which is passed through the frames *E* and *L*, and serves to steady the latter whilst the machine is at work. Beneath the roller *P* a brush or scraper is arranged to clean the surface of the belt *Q*, as it passes under the roller *P*. As here arranged, the brush *v*, which extends across the belt *Q*, is attached to the extremities of the two levers *w*, which are centred upon the transverse shaft *x* that is carried in the framing *E*. The other ends of the levers *w* extend towards the front of the machine, and are connected by a transverse rod. In this manner the brush *v* oscillates upon the supporting shaft *x*, so that it may be caused to press with more or less force upon the belt *Q*. A scraper *y* is also shown as adapted for cleaning the surface of the belt *Q*; this scraper may be a sheet of iron or a rod. In the drawing a sheet of iron is shown which is bolted to the receiver *A*. The trough or receiver *A* is hung upon the axle of the wheels *D*, and to admit of its being readily inverted, in order to discharge the contents of the receiver, a windlass is fitted over its front end. The standards *z* are bolted to the front end of the framing *E*; the windlass barrel 1 is carried upon the shaft 2, which has keyed to one extremity the wheel 3; this wheel is driven by the pinion 4 which is carried upon the end of the shaft 5, projecting from the contiguous standard *z*. Motion is given to the wheel 3 by means of the winch handle 6, and the barrel is prevented from turning in the wrong direction by the pawl 7, which falls into the teeth of the rachet

Digitized by Google

wheel 1 on the shaft 2. A chain 9 is made fast to the barrel 1, and is carried beneath the trough *A*, and fastened to its rear end; upon winding up the chain 9 the front end of the trough *A* is raised and the contents are discharged at the rear end. When emptied the trough is lowered to the horizontal position and secured by the bolt 10, which passes through the framing *E*. With these several improvements the operation of sweeping the streets by mechanical agency may be effected in an expeditious and highly effective manner.

THE SMITHFIELD CLUB SHOW.

Concluded from page 41.)

S. SMITH (late Fisher), of Thrapstone, exhibited his steerage corn drill, never exhibited at the Christmas shows before. This is a handy little implement for small occupations, and suitable for drilling on hill sides. The wheels can be set to any width, and the coulters are renewable at any time. Mr. Smith also exhibited a new double oil-cake mill, fitted with a moveable grating for regulating the size of the broken pieces. It breaks the cake up very regularly, and is sold at the same price as the single mills.

T. Standing, of Preston, exhibited his churns, in which the sun and planet motion is very ingeniously applied, so as to constitute a most efficient apparatus for churning, or, indeed, thoroughly mixing materials for various purposes. It is contemplated to work out the principle in large machines suitable for brewers, dyers, and others.

E. Page and Co., of Bedford, exhibited their "eclipse" plough, a very efficient implement; as also their brick and pipe machine, capable of making the largest size drain pipes with great accuracy and speed.

J. Braby and Sons, of Newington-causeway, exhibited their patent wheels and axles. These wheels have cast-iron naves, the inner surfaces of which are hardened. The front reservoir or cap for containing the oil is made spherical so as to resist concussion. This cap is attached to the nave by bolts, and has a leather washer between it and the nave to prevent the escape of oil. The spokes of the wheels are bevelled where cut down to fit the naves, so as to avoid the weakening effect of sharp angles. Matters of detail of this character are important and deserve notice, exhibiting practical skill and care in the manufacture.

Kingston and Trowbridge, of 116 Aldersgate-street, exhibited a variety of scales and weighing machines. Their scales and weights on single stand, weighing up to 7 lbs., and sold for a sovereign, deserve special mention. This design has been registered by the makers.

Picksley, Sims, and Co., of Leigh, Lancashire, exhibited a large assortment of chaff-cutters, made of ten different sizes. The No. 3 machines are specially notable from their being constructed so that the rollers may be instantly thrown out of gear, the wheel work being protected, their being fitted with hand levers for regulating the length of cut and the improved form of the knives. This firm also exhibited some very efficient grain crushers and turnip cutters.

W. Snowden, of Longford, near Gloucester, exhibited an improved chaff and litter cutter, capable of cutting ten different lengths from 3-8 inches to 6 inches, by an adjusting lever and without change wheels. In this machine all pressure is taken off the straw before the feed movement comes into operation, which renders the work easy, and prevents choking. Mr. Snowden also exhibited Woofe's patent paring plough, of which he is the maker and proprietor. This implement is worked by one horse, and cuts turf one inch thick, and in uniform lengths of about 18 inches, completely turning them over.

J. Eaton, of Thrapstone, exhibited a novel sheep crib, designed to enable the sheep to feed at ease while keeping the food covered. He also exhibited his corn-dressing machine, in which the fine riddles answer as screens, the tail, small seeds and screenings, being effectually winnowed from the grain. These machines are sold as low as seven guineas.

Messrs. Woods, of Stowmarket, exhibited their improved separate gear, or intermediate motion, for horse power, also one of their excellent portable corn mills, with iron framing and wooden gearing.

Hensman and Son, of Leighton Buzzard, exhibited one of Seaman's ploughs, having cast bosses, which can be easily replaced.

G. Turner, of 196 Great Dover-street, Borough, exhibited various machines for domestic use and at very low prices, including sausage machines, domestic flour mills, and an admirable cream whipping machine or egg whisk, fitted with arrangement for screwing to table. The latter machine we saw used, and although very simple in construction, and so calculated to work almost any time without getting out of order, produces marvellous effects upon eggs, three or four of which can be whipped by it into a compact mass, capable of being cut like butter, in about a minute and a quarter. The price of this machine is only 21s. It does in less than a minute and a half what would take a dexterous hand from 30 to 40 minutes to accomplish.

B. Fowler and Co., of Whitefriars, exhibited a very compact double-acting pump (Holman's), mounted on cast-iron base-plate and column, with spur wheel, pinion and drum, and capable of being wrought by a fixed or portable engine. These pumps are suitable for irrigation, pumping liquid manure, or for manufacturing purposes. They are made capable of raising from 1,100 to 17,000 gallons per hour, and are very completely fitted.

S. and E. Ransome and Co., of Essex-street, Strand, exhibited (Long's) new washes or dressings for sheep, &c., which are prepared without mercury or arsenic, and stated to be "non-poisonous." Some splendid samples of wool were exhibited from sheep dressed with one of these preparations. Messrs. Ransome also exhibited a new wrought-iron dressing fork, invented and made by Henry Inskip, of Potton.

R. and J. Reeves, of Westbury, exhibited one of Chandler's liquid drills, with striers, and new arrangement for working the valves from below them. These drills are also fitted with Chambers' drop apparatus, and have a harrow at back.

J. Warner and Sons, of Jewin-street, exhibited their improved double-action fire pump, which is intended to be used as a fire engine, and liquid manure distributor. The arrangement is very compact—pump, air vessel, and valves all being supported on a wheel-barrow frame, so as to be easily removable. We may also notice Messrs. Warner's new mode of making the pump valves of iron, faced with india rubber, as also the buckets which have leather packings bolted between iron plates.

G. Kent, of 199 High Holborn, exhibited Griffiths' beating, mixing, and churning apparatus, similar in construction to those we have already noticed for whipping cream or whisking eggs and designed for the same purpose. These machines are sometimes provided with an external casing for containing hot or cold water for regulating the temperature of the material operated upon.

James Haywood, jun., of Derby, exhibited his two-horse portable engine with vertical cylinder, all the tubes of the boiler being screwed in. The feed pump is made with a regulating valve for overflow of water, and the funnel is made detachable for easy transport. Mr. Haywood is now constructing thrashing machines suitable for these small engines.

Ransome and Sims, of Ipswich, exhibited a very large assortment of machines and implements, of course including their new horizontal root-cutters, which gained the prize at Chester. This firm, as the constructors of Fowler's steam ploughing apparatus, exhibited drawings of this machinery, which was at work during the show near the Redhill station and at Cann Hall Farm, near Stratford. Fowler's steam plough, taken in connection with his system of working it, has now obtained £825 in prizes, including the £500 prize given at Chester, after three years' competition, by the Royal Agricultural Society.

Smith and Ashby, of Stamford, exhibited one of their two-horse portable engines, with newly-arranged doors for enabling the tubes to be cleaned without taking off the front plate. Also their chaff-cutters, with improved pegged and fluted rollers, calculated to ensure a continuous feed without liability of choking. This firm have also introduced several improvements in their hay-making machines, adapting them for cutting thistles by a slight addition to them. The springs being made of double the ordinary strength, the machines also answer as manure distributors. Messrs. Smith and Ashby also exhibited a newly-arranged small portable corn-grinding machine.

Wm. Cambridge, of Bristol, exhibited a model of an ordinary portable engine, fitted with Boydell's endless railway. By adopting a simple steering apparatus, Mr. Cambridge believes ordinary portable engines may be cheaply fitted with Boydell's wheels, which enable them to be self-moving, at small cost, and at the same time suitable for working in the usual way. The model exhibited was very well arranged, and turned in its own length, the endless railway being dispensed with on the single fore-wheel with which the engine was fitted.

W. Smith, of Mark-lane, exhibited a model of his well-known steam-ploughing apparatus, which received a gold medal at Chester. The apparatus was at work on Flemish-farm, near Windsor, during the show. The great recommendation of Mr. Smith's plan of steam-ploughing is the cheapness of the apparatus—the ordinary portable engine costing from 235*l.* to 250*l.* only, and the whole ploughing apparatus, including 1,400 of iron rope, 192*l.*

Spencer Read and Co. exhibited a good collection of photographs of machinery, as also of cattle—which latter this firm have been the first to take—that is, of all animals exhibited at the agricultural shows. The rapidity and accuracy with which likenesses of favourites can be thus taken will doubtless lead in time to the public being supplied with portraits of all the prize animals at a merely nominal cost.

We have now gone carefully through the whole of the stands where any matters of novelty were exhibited, and have said enough to give those who could not attend the show a fair notion of what was to be seen. Our remarks have necessarily been very much compressed from want of space, but we believe nothing of importance has been overlooked.

COVERINGS FOR FLOORS, &c.—The production of a good, durable, and cheap covering for floors, embracing the advantages of softness and elasticity, has long been sought for. Carpets, whether of Brussels or Kidderminster, are expensive, and soon show signs of wear, besides which they are not adapted for halls, offices, or public buildings. To meet this want a composition called Kamptulicon has been extensively introduced in churches and other places, but after trial has been discarded as useless, on account of its extreme brittleness—or, perhaps, "*shortness*" would be a better term—as after it has been down for some time it breaks or crumbles on being taken up, very much like oat-cake. This may be a defect that possibly in time might be overcome by experimenting with the composition of which it is made, though most likely the result would be a hard compound. We have made these remarks to introduce a very beautiful invention especially designed for the purposes in question. The patentee is Mr. Dunn, of Messrs. Charles Goodyear and Co. (the inventor of the Vulcanization of Indian Rubber), for combining a mixture of cork, cotton, wool, and other fibrous materials of any colours and fineness with India Rubber, and spreading them upon a canvas, cotton, or woollen back, which is then subjected to a process by which the carpet in embryo can be embossed, either plain or in colours, the result being a material of great permanence and beauty. It has all the softness of the carpet with an elasticity and noiselessness of tread that constitutes the beauty of a real velvet pile Brussels, and there is very little doubt will supersede anything now in use—even the old oil-cloth of our childhood.

NOTICES.

Numbers 1845 and 1846 of the MECHANICS' MAGAZINE (original series), containing the paper read at the Society of Arts, Dec. 15, 1858, "ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWERS OF ATTACK AND DEFENCE," by one of the EDITORS of this Magazine, together with the discussion upon the same, are still on sale.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 6d. per line for any number of insertions less than 13; for 13 insertions, 5d. per line; and for 52 insertions, 4d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can be received after 9 o'clock on Friday morning for the ensuing number.

TO CORRESPONDENTS.

R. Armstrong.—The proposal suggested by you has been contemplated, and will be carried out speedily.

J. A. Davies.—Thanks for letters. The weekly list of contents will not be necessary after the half-yearly index has appeared, and the volume is bound.

W. Bennet—The prices current of metals will be regularly published each week for the future. Their non-appearance last week resulted from a misunderstanding.

K. K.—It is quite possible, and even probable, that we shall find it necessary to still further enlarge our Magazine before very long; but no further advance in the price will be made.

We have to thank several correspondents for letters on the "Conservation of Force." We desire it to be known that our excellent correspondent, "A Mechanic," undertook the series of letters in course of publication at our request, and we can give place to no criticisms upon them until the series is concluded.

*** The conclusion of the report on "Shipping Statistics" is unavoidably deferred until next week.

Law Cases.

SPENCE'S PATENT TIN AND LEADEN PLATES.

COURT OF CHANCERY, Lincoln's-Inn, Jan. 12.—Before the LORD CHANCELLOR.

RE SPENCE.

THIS was a petition of James Spence, of Liverpool, praying that the great seal might be attached to a patent for an improvement in the manufacture of tin plates and terne or leaden plates, notwithstanding a *caveat* which had been entered by Messrs. Clay, of the Mersey Ironworks, Liverpool, and Messrs. Vickers Benzon, of Sheffield, on the ground that the article of "puddled" steel, upon the application of which the patent was sought for, was not a new invention.

Mr. Malins and Mr. Webster (of the common law bar) appeared for the petition; Mr. Hindmarch and Mr. Drewry were for the opposition.

The LORD CHANCELLOR said that this was one of the cases in which the question in dispute between the parties ought to be tried at law. By refusing to seal the patent this Court would prevent such right from being exercised, and therefore the proper course would be to order the patent to be sealed.—Ordered accordingly.

The above report has been furnished by the ordinary reporter. The following letter, however, puts the matter in a somewhat different light:—

To the Editors of the MECHANICS' MAGAZINE.

"Gentlemen,—The shorthand writer for the papers not being an "expert" has fallen into error in his report of this case. The statement sent forth by the *Times*, and other journals, makes it appear that the invention of Puddled Steel (patented by Mr. Ewald Riepe) was not a novelty. This was never mooted, and is unquestioned. Mr. Spence's application was for a patent for making tinned plates from puddled steel, which was opposed by Mr. Clay (Mersey Steel and Iron Co., Liverpool), and by Mr. Benzon (Naylor, Vickers, & Co., Sheffield), on the ground that Mr. Spence cannot claim a patent for using *puddled* steel for tinned plates, as tinned plates have been previously made from steel manufactured in the ordinary way, and that therefore there was no novelty in steel tinned plates, and that if there were that Mr. Clay suggested the idea to Mr. Spence. The Lord Chancellor allowed the great seal to be attached to Mr. Spence's patent, stating as his reason for so doing, that if he refused it Mr. Spence would be deprived of all redress, whereas if he granted it, the opponents to the application would have their remedy by trying the issue at common law, adding, that this was just a proper case to go to such a tribunal, and which course will be adopted. As the MECHANICS' MAGAZINE is read by practical men, it is desirable that this matter should be correctly placed before them; and as you will doubtless report the case, may we request you to permit this explanation to appear in your next publication, and oblige Your obedient servants,

The MERSEY STEEL AND IRON Co.,
per W. Y. V., Jun.

NORTON'S REGISTERED SHAWL.

COURT OF QUEEN'S BENCH, Westminster, Jan. 14.—Sittings in Banco, before LORD CAMPBELL and Justices WIGHTMAN, CROMPTON, and HILL.

NORTON *v.* NICHOLLS.

MR. KNOWLES, Q.C. (with whom was Mr. Webster), moved, pursuant to leave reserved, for a rule calling upon the plaintiff to show cause why the verdict found in his favour should not be set aside and a nonsuit entered, or why the verdict should not be entered for the defendant. The action was brought to recover damages for the infringement of the plaintiff's design of a shawl registered under the 5th and 6th Victoria, cap. 100. The plaintiff's case resolved itself into five points, which constituted the alleged design. 1. It had a reversible or double texture; 2. it had a scallop which was said to be a new design; 3. whereas the body of the shawl was double, the border was single; 4. one of the four corners was rounded; and, 5., the fringe was of a particular manufacture. Only the 2nd and 4th came within the Act—viz., the scallop and rounded corner—and they were both old; but the plaintiff claimed the combination of the five points as constituting a new design within the Act, which was the question now to be determined. There was also a question as to the notice given to the defendant, who was the vendor, as required by the 7th section.

Lord CAMPBELL said the learned counsel might take a rule to show cause.—Rule *nisi* granted.

SHIPBUILDING ON THE WEAR.

SOME sensation has been created this year by the publication of the annual statistics in reference to the shipbuilding trade on the Wear. The following table shows the number of ships built at Sunderland since 1847, with their aggregate and average tonnage:—

Year.	Ships Built.	Aggregate Tonnage.	Average Tonnage.
1848	142	37,878	266¾
1849	155	44,333	286
1850	158	51,374	325¼
1851	146	51,823	355
1852	142	56,645	398¾
1853	152	68,479	454½
1854	151	66,929	443¼
1855	151	61,159	405
1856	154	63,047	409¼
1857	143	54,780	383
1858	110	42,003	381¾

It appears, from the following classification, that there has been no falling off in the quality of the build:—

	Class.									
Years.	5	6	7	8	9	10	11	12	13	14
1850	1	3	13	88	17	15	0	7	13	1
1851	1	3	8	81	17	14	2	7	13	0
1852	0	2	6	74	6	25	1	6	20	0
1853	2	0	4	77	10	25	0	5	27	0
1854	0	1	7	86	13	19	1	2	21	0
1855	0	0	8	67	32	22	3	1	16	0
1856	0	0	7	50	33	23	11	1	27	0
1857	1	0	4	51	43	18	10	2	14	0
1858	1	0	2	36	24	23	7	1	15	0

1 not classed.

The smallest vessel built last year was the *Derwent*, 49 tons, and the largest was the *Holmsdale*, 1,257 tons. Sunderland is her own best customer as regards the ports to which her ships are sold, and Shields and London rank next.

There is very little iron shipbuilding on the Wear, only one builder (Mr. Laing) being so engaged. In 1857 one iron vessel of 610 tons was built, while last year three ships of an aggregate tonnage of 2,160 tons were turned out.

INDIAN ITEMS.

A STEAM ferry is to be established on the Indus at Attock. Steam ferries, it is stated, will be more numerous in future on the Indian rivers. At present, however, considerable difficulty is experienced in repairing engines when they get out of order.——A railway bridge of stone and iron, projected over the Jumna, will be a great work when carried out. The following are a few details on the subject:—Length of bridge between faces of abutments, 3,224 feet; number of openings, 15; distance from centre to centre of piers, 219 feet 9 inches; spans of openings in the clear, 205 feet; and depth of the bottom of foundations below low water level, 50 feet. The railway will be 81 feet above the low water level. The iron work of the bridge is, it is understood, being executed at Newcastle.——The Kurrachee Cantonment Water Company is to be dissolved, 20,000 rupees having been expended without success.

THE FOUNDER OF THE LONDON MECHANICS' INSTITUTION.—The *Times* having alluded in a leading article to Lord Brougham as the founder of the above Institution, Mr. Hodgkin, who was assistant to the late J. C. Robertson, in 1823, has written to the newspapers, stating and proving that it was Mr. Robertson, the founder and first editor of the MECHANICS' MAGAZINE, who originated it. This statement was made some months since on a somewhat similar occasion, but the present Managers of the Institution have chosen to ignore the fact, and to continue to propagate the false belief in Lord Brougham's origination. They deserve the evils which have come upon them. At the same time we wish them well out of their difficulties, while despising their misrepresentations.

WOOD CARVING BY MACHINERY AND HAND LABOUR.—We are happy to find that the really beautiful machines which were formerly worked under the Jordan patent in the Belvidere-road, Lambeth, and to which the Houses of Parliament, and many other important buildings in Europe are indebted for their carved woodwork, have not shared the fate of the company that fruitlessly attempted their commercial development, but are now in active and profitable operation under the management of Messrs. Cox and Son, the well-known ecclesiastical furniture-manufacturers, who, after purchasing them, removed them to some new premises exactly opposite their former *locale*. The reason of the previous failure of this machinery would appear to have been that too much was required of it, and its present success is attributed to the confining of its operations to merely the rough definition of the form and pattern desired, and the calling in of hand labour to finish and perfect. By this a vast saving in the cost of the most ornate wood carving is effected, and consequently the demand for ornamentation of this description has increased to an extent which it is said will shortly compel the Messrs. Cox to double the number of the machines employed by the late company.

NOTES FROM THE EASTERN DISTRICTS.

[FROM OUR OWN CORRESPONDENT.]

The London, Dunmow, and Bury St. Edmunds Railway—Brick and Timber Bridges—Landing Stages at Ipswich—The New Telegraph Line to the Continent—Rating of Gas Company—Gas at Watton..

THE projected direct railway from the metropolis to Bury St. Edmunds *vid* Dunmow and Clare will not—at least so says a local paper—be proceeded with in the ensuing session of Parliament. The reason given is the late period of the season at which the affair was taken in hand. The plans and surveys are, the same authority consolingly adds, available for a future year.—A long timber bridge on the Great Northern Railway at Bardney has been for some little time past in such a condition that the Company has determined to substitute for it a brick and stone structure. This will involve an expenditure of £10,000, and the contract has been let to Mr. Jay, of London.—The Ipswich Dock Commissioners have determined to have two landing-stages at that port. One of them is nearly finished, and the engineer has been instructed to proceed with the second.——There has been a good deal of talk lately about a new telegraph from the metropolis to the continent *vid* Norwich, and it was stated a month since that the line would be ready for the transmission of messages by this time. The company (British and Irish Magnetic) seems to have met with unexpected difficulties in passing through some of the towns on the way, the original plan having been departed from at Norwich, while at Newmarket it is said the wires will have to be carried underground.—The Cambridge Gas Company occupied the local sessions two days at the close of last week with an appeal against the valuation of the property by the guardians, and the poor-rates consequently levied. The proceedings were tedious in the extreme, three learned counsel being retained on each side. At last the Recorder gave judgment, and decided that the assessment of the company's property should be £1,700. The company urged that it should be £750, and the guardians put it at £2,400. Mr. O'Malley, Q.C., on the part of the company, applied for a case for the opinion of a superior court. This was granted by the Recorder, who said he would respite the appeal against the rate sought to be imposed from session to session until judgment was given by the superior court. Evidence was given in the course of the proceedings by several gentlemen of experience in gas matters, but as the case involved merely matters of detail, it did not present features of general interest.—Steps are being taken to extend the benefits of gas lighting to the town of Watton, Norfolk. The necessary works will require an outlay of £1,200, and this sum is to be raised by a company formed under the Limited Liability Act.——Before an inventor of an agricultural implement can exhibit at the future meetings of the Norfolk Agricultural Society, he must pay an annual subscription of one guinea.

NOTES FROM THE SOUTH WEST.

[FROM OUR OWN CORRESPONDENT.]

Somerset Central Railway: Wells and Glastonbury—Little Down and Ebber Rocks Mineral and Mining Company—Drinking Fountains for Southampton—The Water Supply of that town—Public Clocks—New Steamers for the Turkish Government—The Naval Service—London, Bristol, and South Wales Railway—Steamers for the Brazilian Coasting Trade—The Screw-Steamer Mauritius—The Royal Engineers—Organ for Barbadoes—Bristol Trade: Accommodation for Ocean Steamers.

THE chairman and directors of the Somerset Central Railway have made an experimental trip over the new portion of the line between Wells and Glastonbury. The contractor's engine left Glastonbury at 12·30, and arrived at Wells shortly before one. The works are very forward, and it is expected that the line will be ready for traffic in the course of February.——It is understood that a limited liability company has agreed for the purchase of the Little Down and Ebber Rocks estate on the Mendip Hills, with 235 acres of adjoining land, in order to develop its resources. The estate lies in Wookey and Wells, in Somersetshire, and is reported to contain vast deposits of manganese and iron, ochre, argentiferous lead ores, and other products. The prospectus is a very sanguine one, and states that the price to be paid for the property under consideration is £40,000. ——Mr. Melly (of Liverpool) has kindly offered to supply gratuitously to the town of Southampton a polished granite drinking fountain with appurtenances. Mr. Pegler has offered to pay the expenses attendant on the erection. Mr. Cooksey has also offered to supply, at his own expense, a drinking fountain, and suggests the bottom of Bernard-street as a fitting site.——The average quantity of water supplied to Southampton from the new reservoirs, exclusive of the old reservoirs, is reported to be 705,925 gallons by day, and 464,887 gallons by night. Some complaint has been made of the great consumption of coals at the works, but it is stated that this is to a great extent attributable to the waste of water, especially at night. In Southampton 6,653 houses are supplied with water, exclusive of a number of public and private establishments. The consumption is estimated at 185 gallons per house per diem; and it is stated that in London, in 1850, the supply was 164 gallons per house, and in 1856, 246 gallons. The subject of the erection of additional engines at Mansbridge has been referred to the Special Works Committee of the Local Board of Health, with power to consult Mr. Summers and obtain from him a report as to the power of the present engines, and their capability of supplying the quantity of water required for the town, and also whether the present staff of men employed are required for working the engines, and what quantity of coals it is necessary to consume.——The same committee of the same board has also had referred to it a suggestion as to the propriety of regulating the public clocks of Southampton, a clause in the act under which the local board is constituted authorising it to establish and take care of clocks. The town-clerk (Mr. Deacon) expresses his opinion that the clause does not apply to church clocks.——One must strain a point, and pass over a little blue water to notice the interesting fact that the keels for four new steamers for the Turkish Government have been laid in the ship-building yard of the Messrs. White, at Cowes. They are to be despatch boats, and the tonnage of the largest will be 300 tons.——*On dit*, that it is the intention of Sir John Pakington, the present First Lord of the Admiralty, in distributing to distinguished naval officers the few rewards of meritorious conduct which are at his official disposal, to divide them as equally and fairly as possible among the most deserving officers, and not to give good service pensions to the superintendent of docks or victualling yards, or officers holding other profitable appointments during the time of their holding such positions.——Mr. James Spence, chief foreman of the steam factory, Portsmouth Dockyard, has been presented by his brother officers with a handsome gold watch, as a proof of their appreciation of the zeal, energy, and intelligence displayed by him in the matter of their superannuation.——In the matter of the London, Bristol, and South Wales Railway, it has been decided to make a return to the shareholders of the assets, and to finally wind up the affairs of the undertaking.——Two steamers have been recently constructed in the north, for the Brazilian coasting trade. One of these has been named the *Gonçalves Martins*, and the other the *Valeria do Sinimbee*, and they are the property of the Bahia Steam Navigation Company. They are to be employed in the coasting trade between Bahia and the ports north and south, and have each accommodation for 120 first and 40 second-class passengers, exclusive of captain, officers, and crew. The following are the leading details of the *Valeria do Sinimbee*, which closely resembles the *Gonçalves Martins*—is, in fact, a sister ship:—length between perpendiculars, 200 feet; extreme breadth, 26 feet; depth of hold, 11 feet 9 inches; burden in tons (o.m.), 663; tonnage per register, 374·1. The engines are of 120-horse power, and are on the oscillating principle. The *Valeria*—one must shorten such a hard name—will carry 140 tons of cargo and fuel for five days on a draught of 7 feet 6 inches. On a trial trip from Hartlepool to Southampton, a speed of 12½ knots per hour by patent log was attained. Both vessels were designed by and built under the superintendence of Mr. Herbert L. Thompson, naval architect in connection with the firm of Messrs. A. Brett and Co., Leadenhall-street. The *Gonçalves Martius* has already arrived at Babia, and the *Valeria do Sinimbee* (which is named after the late president of the province of Bahia) is on her passage out.——The screw-steamer *Mauritius* which was recently employed as a government transport to India and China, has been thoroughly overhauled, since her return from eastern waters, by Messrs. Summers and Day, of the Northam factory. On a trial trip in Stokes Bay, the other day, she attained an average speed of 10·935 knots per hour, her draught of water being 14 feet 9 inches forward, and 16 feet 2 inches aft; pressure of steam, 14 lb.; average revolutions of engines, 48. The *Mauritius* is 2,125 tons register, and 300-horse power; she is fitted with a Griffith propeller, 15 feet 6 inches diameter, and 25 feet mean pitch.——Lieut. E. R. James, Royal Engineers, has been appointed from special service to ordnance survey, Southampton.——Messrs. Smith and Sons, of King-square, Bristol, have completed a fine and powerful organ for Barbadoes Cathedral, West Indies.—— The trade of the port of Bristol is increasing, as appears by the customs receipts for the past three years. In 1856 these receipts were £1,193,378; in 1857, £1,212,357; and in 1858, £1,295,559. The increase arises entirely from augmented commerce with foreign countries.——It is stated that an engineer in Bristol has a scheme for providing accommodation in the port for ocean steamers; and some interest appears to be felt in the subject. "The first improvement," writes a correspondent of a local paper, "should be the removal of the heap of mud known as 'the swash,' from the river's entrance. This accomplished, there would be depth of water from Sea-mills to King-road sufficient to enable steamers to arrive at and depart from the former place at all states of the tide; and by dredging, accommodation could be found for the largest vessels."

METAL AND COAL TRADES, &c.

[FROM OUR OWN CORRESPONDENT.]

Quarterly Meetings of the Iron Trade—South Wales Trade—North of England Iron Trade—St. Helen's Trade—Trade of Blackburn—Birmingham, Wolverhampton, and South Staffordshire Trades—South Staffordshire Colliers and the Coal Trade there.

THE Quarterly Meetings of the Iron Trade have passed, as it was previously anticipated they would do, without any change in existing prices, but with the prevalent opinion that the prospects of the trade are of a satisfactory, indeed, of an auspicious character, notwithstanding the unpleasant turn which matters have unexpectedly taken in connexion with foreign affairs. It is understood that within the last week or two many orders have been received from Australia and India, and from the United States, and that all the principal makers are well supplied with orders.

It is stated that there has been a larger quantity of finished iron sold at the late Quarterly Meetings than on similar occasions for two or three years past, and that the business transacted has been of a *bonâ fide* character.

There seems to be no doubt that the almost empty condition of the warehouses of the iron merchants at home and abroad will shortly lead to an increased demand. A large number of orders for rails and railway iron plates for various purposes must of necessity, it is said, be in the market in the course of a few months.

In the South Wales district the iron trade remains *in statu quo*. The dulness usual at this season of the year is prevalent. Prices have undergone no alteration. The coal trade is somewhat unsettled; but one or two fresh government contracts have caused a little more animation.

In the Northumberland and Durham districts, the coal and iron trades show signs of increased vitality

In the Derbyshire district increased buoyancy has begun to be manifested in several departments of business. For merchant bars there is a fair demand, sheets and plates are in more general request, whilst for railway iron-work there is a briskness in the demand which has not been experienced for some time past.

There is as yet but little improvement in any branch of manufacture at St. Helen's, and great numbers of skilled workmen continue out of work. The foundries have rather more doing, and at one place the turners have struck work to obtain the same rate of wages as was given before the last reduction.

The general improvement in the trade of Blackburn has caused the whole of the mills that were standing twelve months ago, with one exception, to be sold or taken. The first sod has been cut for a new mill; it is to contain preparations for 20,000 spindles. Others are talked about.

The manufacturing trades of Birmingham, Wolverhampton, and the surrounding districts do not afford much matter for comment; no perceptible change having taken place within the last few weeks. Generally full time is being worked.

The colliers of South Staffordshire have issued an address to their masters, asking for a rise of 6d. a day, but as coal has not yet got up sufficiently to warrant an advance, their application will not be granted.

CURRENT EVENTS

IN THE CENTRES OF THE IRON, COAL, MACHINE AND SHIPPING TRADES.

[COMPILED BY OUR OWN CORRESPONDENT.]

Commencement of a Railway Viaduct—The Tender for the Eden Valley Railway—Preston "Watching" a Railway Amalgamation Bill—The Indian Telegraph Cable—New Docks at Liverpool—Entries into Liverpool in the past two years—Wrecks in Liverpool Bay—Iron Ship Launch—Sunderland Shipwrecked Mariner's Society—Havelock Memorial—Preston Operatives and the Factory Act—Coating Iron Boilers with Zinc—Working Man's Institute Building in North Staffordshire—Opposition to Machinery—Serious Strike of Colliers—Association for Prevention of Steam Boiler Explosions—Isle of Man Telegraph—Discovery of Coal 1,000 feet above the Sea Level.

THE ceremony of laying the first stone of the Dellicar viaduct at Lowgill, on the Lune Valley Railway, has been performed. The engineer, J. E. Errington, Esq., (of Messrs. Locke and Errington), delivered the opening address, stating that the work about to be commenced was of great magnitude, consisting of a viaduct of 11 arches of 45 feet span, more than 100 feet in height, and containing about 400,000 cubic feet of masonry.——The tender of Messrs. Lawton Brothers, contractors, of Newcastle-upon-Tyne, has been accepted for the construction of the Eden Valley Railway, which commences at Clifton Station, near Carlisle, and terminates at Kirby Stephen, being a distance of 22 miles.——The Preston Town Council have appointed a committee "to watch the Lancashire and Yorkshire and East Lancashire Railways Amalgamation Bill, and to take steps for protecting the interests of the borough, and limiting the amount to be charged by the amalgamated companies for tolls and carriage."——The length of cable for the Indian telegraph from Suez to Aden, manufactured by Messrs. Newall and Co., was to have been despatched from Liverpool yesterday the 20th instant, in two vessels.——The association for the prevention of steam boiler explosions held their annual meeting in Manchester Town Hall on Monday. Mr. Wm. Fairbairn, C.E., F.R.S., president, occupied the chair. The report of Mr. R. Longridge, the late chief inspector, showed that the number of boilers under inspection at different periods was—In 1856, 1,401, the income being £1,285; 1857, 1,532, with an income of £1,599; 1858, 1,561, with an income of £1,638. The revenue of the year was £1,757 3s. 6d.; and the balance remaining

Digitized by Google

in the Bank was £1,051, against £1,003 at the commencement of the year. "On the whole, the committee regard the financial portion of the Association with greater confidence than hitherto." The ordinary services rendered by the officers had been—Visits by chief inspector, 513; quarterly visits by sub-inspectors, 2,580; thorough internal and external examinations, 235; annual indications of engines, 603. Special services: Examinations by sub-inspector, 114; additional indications by sub inspectors, 138; special indications by the same, 6. The committee regret that although provision was made "for one thorough internal and external examination per annum of every boiler under their superintendence, yet only 235 such examinations have been made, out of a total of 1,561." Adding the 114 special examinations, the total was only 349. As regarded the important question of the incrustation of boilers, the committee "as a basis for further investigation, have deemed it expedient that the water supplying boilers in various parts of the district should be analysed;" and Dr. R. A. Smith was engaged in that object. The chairman, in moving the adoption of the report, said that he had recently investigated the causes of explosion from collapse of flues, and had found that the strength of a flue was in inverse proportion to its length. A flue of 15 feet in length would bear twice the pressure per square inch of one of 30 feet. He was also about to carry out some experiments with respect to surcharged and combined steam.——The Isle of Man Telegraph Company is proceeding very satisfactorily with its preliminary labours. Shares covering a sum larger than the capital required, are understood to have been already applied for.——The Park Lead Company, whilst sinking another shaft from the top of of a high mountain, at Minera, near Wrexham, in search of ore, have discovered a stratum of coal about 500 feet above the valley, and 1,000 feet above the level of the sea.——The New Liverpool Dock Board have resolved to apply to Parliament or powers to borrow £300,000 for the purpose of improving and extending the Liverpool Docks——The *Customs Bill of Entry* gives the following as the number of vessels registered at the port of Liverpool:—For the year ended December 31, 1857, 2,339 vessels and 936,073 tons; for the year ended December 31, 1858, 2,395 vessels and 953,955 tons: increase on the year 1858, 56 vessels and 17,882 tons.——From the return of wrecks in Liverpool Bay, it appears that during last year (1858) 25 vessels were wrecked. Of these 12 were totally lost, and the remainder, with four exceptions, either raised or removed. Other statistics show that during 1858, 16,726 vessels passed inwards, through the Victoria and other northern channels, to and from Liverpool. This makes a total intercourse of 34,402 vessels. During 1857, the total intercourse was 39,139.——There has just been launched from the building yard of Mr. J D. Marshall, South Shields, a new iron paddle-wheel steamer, to be fitted with a pair of engines of 60-horse power nominal. It is of the same size and power as the four steamers previously sent by the same builder to St. Petersburg and Liverpool.——The Twenty-fifth Annual Meeting of the Sunderland Shipwrecked Mariners' Society has been held. The report stated that during the past year the committee had relieved 35 widows, with 46 children, to whom they had distributed the sum of £111. The total number of cases relieved by the society since its formation in 1833, was stated to be 779 women, and 1,533 children, and the sum expended in relief had been £2,688 19s. —— The Sunderland Havelock Memorial Committee have resolved that the memorial shall be a colossal statue in bronze, figure not exceeding nine feet, mounted on a granite pedestal from ten to twelve feet high. The designs are to be received on the 7th of February next.——The Preston operatives have resolved to memorialise the Home Secretary for a more stringent enforcement of the Factory Act, which "has been and is being openly and grossly violated."——Two persons have been nearly poisoned in Berkshire from drinking wine that had been boiled in an iron boiler coated with zinc. The *Berkshire Chronicle* says:—"It is evident that galvanised iron boilers are quite unfit to be used for making of wine, or boiling fruit of any kind, as the acid in the fruit dissolves a portion of the zinc, forming a highly poisonous solution."——A beautiful building for the purposes of the Working Man's Institute, Hartshill, Stoke-upon-Trent, erected at the sole expense of Colin Minton Campbell, Esq., at a cost of some £600, after a design of Mr. Robert Edgar, architect, has been opened to the public.——"The United Society of Cordwainers of Stafford" have issued an address calling upon their fellows to resist to the utmost any attempt by the masters to introduce into that town machines for binding boot tops, and to refuse to work up any tops so bound. These machines are already in use at Kendal and other places.——A strife of a serious nature has taken place between the unionists amongst the colliers of Wigan and the police there; the colliers in question determining to prevent any of their number from returning to work, assembled "many thousands" strong, it is said, pelted the police with stones, and threatened to fire upon them if they further attempted to prevent them from carrying out their object. The arrival of the military from Manchester restored order.

PROVISIONAL PROTECTIONS.

Dated October 11, 1858.

2258. J. Saxby, of Brighton, Engineer. Improvements in apparatus for working signals on railways.

Dated November 30, 1858.

2724. J. Luis, of Welbeck-st. A watch, simplified with anchor escapements and rack, forming a double lever, catching in the pinion of its balance wheel. A communication from A. Lepage.

Dated December 16, 1858.

2884. J. H. Selwyn, of Grasmere, Westmoreland, Captain R.N. A novel apparatus for paying out or laying down submarine telegraph cables or wires, and for raising the same after they have been laid down.

Dated December 18, 1858.

2900. J. MacKenzie, of St. Martin's-le-Grand, Gas Engineer. Improvements in those gas burners known as ventilating sun burners.

2902. J. Taylor, of Birkenhead, Engineer. Improvements in the construction of pumps or engines for lifting and discharging water.

2904. E. Weber, of Mulhouse, Chemist. Improvements in dyeing or colouring textile fabrics and materials, and in the machinery or apparatus connected therewith.

2906. J. H. Johnson, of Lincoln's-inn-fields. Improvements in apparatus for reworking the waste steam of steam engines. A communication.

Dated December 20, 1858.

2908. S. Hunter, of Newcastle-on-Tyne, Gentleman. Improvements in the construction of anchors.

2910. J. Ronald, of Liverpool, Merchant. An improved machine for the direct spinning of hemp, flax, and other like fibrous materials.

Dated December 21, 1858.

2912. F. Winter, of Hoxton, Manufacturer. Improvements in the preparation and application of varnishes for waterproofing paper, linen, and textile fabrics, and coating the same with metallic foils.

2914. W. E. Dando, of Pennsylvania, Clerk. Improvements in apparatus for lowering boats from ships or vessels, and also for raising the same as required.

2918. N. Dawson, of Poplar, Stationer. Improvements in order books.

Dated December 22, 1858.

2922. G. Sharp, of Jarrow, Durham, Millwright, and W. Elder, of the same place, Engine Smith. Improvements in furnaces and steam boilers.

2926. E. T. Dunn, of Hammersmith, Gentleman. Improved fabrics suitable for the covering of floors, walls, and other like purposes.

2928. M. Shuldham, of Dursley, Gloucester, Commander R.N. Improvements in ships and vessels, and in working parts of their gear and rigging.

2930. A. Prince, of Trafalgar-sq. Improvements in ornamenting and illuminating surfaces of glass.

Dated December 23, 1858.

2932. D. Lichtenstadt, of Peckham, Chemist. Converting a certain vegetable substance into fibrous material for the manufacture of textile and other fabrics.

2934. T. Bird, of Manchester, Engineer. Improvements in spinning, and in the manufacture of cop bottoms or cop tubes.

2936. J. Whitelaw, of Dumfermline, Ironfounder. Improvements in sewerage and drainage apparatus.

2938. J. Maudslay, of Lambeth, Engineer. Improvements in the construction of ordnance and projectiles to be used therewith.

Dated December 24, 1858.

2942. J. W. Child, of Halifax, Engineer. Improvements in dyeing wool and other fibres.

2944. E. Fellows, of Canterbury, Clerk. An improved vent peg.

2946. J. Railton, of Blackburn, Machine Maker, and S. Lang, of the same place, Mechanic. Improvements in looms.

2948. A. Smith, of Humbleton Hall, York, Agriculturist. Improvements in gigs, dog carts, and other vehicles.

2950. J. H. Johnson, of Lincoln's-in-fields. Improvements in the permanent way of railways. A communication from C. E. Detmold, of New York.

2952. W. B. Johnson, of Manchester, Engineer. Improvements in the employment of gas for generating steam, and in engines connected therewith.

Dated December 27, 1858.

2955. T. Steven, Ironfounder, and T. Scott, Engineer, of Glasgow. Improvements in heating apparatus for culinary and warming purposes, and in part applicable to steam-boiler and other furnaces.

2956. J. Smethurst, of Guide Bridge, Lancashire, Engineer. Certain improvements in metallic pistons.

2958. W. A. Gilbee, of South-st., Finsbury. Improvements in treating fatty bodies, and in the apparatus employed therein. A communication.

2959. J. Macpherson, of Aberdeen, Comb Maker. Improvements in solidifying the raspings and other waste of horns and hoofs, and in applying the process to the cementing of prepared horns, hoofs, and tortoiseshell.

2961. C. M. A. Marion, of Paris, Manufacturer. An improved box or case for containing and preserving sensitive photographic paper.

2963. H. Lowe, of Birmingham, Manufacturer, W. Trueman, of Birmingham, Axle Maker, and J. L. Pitts, of Birmingham, Accountant Clerk. A new or improved axle for carriages.

2964. R. Hornsby, jun., of Grantham. Improvements in ploughing and tilling land by steam power, and in apparatus employed therein.

Dated December 28, 1858.

2965. B. Browne, of King William-st., London Bridge. Certain improvements in the manufacture of boots and shoes, or other coverings for the feet, and in the mode or method of uniting the same, or parts thereof. A communication.

2966. J. Sinclair, of Dublin, Turner. Improvements in pistons.

2967. T. Warren, of Glasgow, Bottle Manufacturers. Improvements in the manufacture of glass bottles.

2969. J. Leck, of Glasgow, Bleacher. Improvements in drying textile fabrics and materials.

2970. C. Fay, of Manchester, Carriage Builder. Improvements in railway carriages and brakes.

2971. J. H. Johnson, of Lincoln's-inn-fields. Improvements in the manufacture of boots and shoes or other coverings for the feet. A communication.

Dated December 29, 1858.

2972. W. Haworth, of Todmorden, Cotton Spinner, and W. Barker, of the same place, Overlooker. Improvements in the top clearers of machines for spinning.

2973. T. Welton, of New Compton-st., Soho, Artificial Limb Maker. Improvements in giving or obtaining publicity, and of advertising either by day or by night.

2974. E. W. Carter, of Rochdale, Cutler, and J. D. Abrams, of the same place, Machinist. Certain improvements in sewing machines.

2975. W. Taylor, of Nursling, Gentleman, and W. D. Grimshaw, of Southampton, Engineer. Regulating the admission of natural atmospheric air and eduction of rarefied air or gases from hotheuses or any other place or premises, and for supporting a required temperature.

2976. R. D. Kay, of Accrington, Manufacturer. An improved chemical means of applying or fixing on woven or felted fabrics certain colouring matters produced from tar.

2977. T. Pickford, of Mark-lane, Merchant. Improvements in the preparation and manufacture of manure.

2978. H. Hutchinson, of Paris. Improvements in the manufacture of india rubber goods.

2979. S. Morand, of Manchester. Improvements in apparatus for stretching fabrics.

2980. A. V. Newton, of Chancery-lane. Improvements in machinery for reaping and mowing. A communication.

2981. T. W. Gowing, of Camden Town, Veterinary Surgeon. An improved roughing for the shoes of horses and other like animals.

Dated December 30, 1858.

2982. H. N. Maynard, of Crumlin, Monmouth, Engineer. Improvements in anchors, and in the manufacture of anchors.

2983. F. Puls, of Roxburgh-terrace, Haverstock-hill, Chemist. The treatment of hydrocarbons.

2985. F. Johnson and J. H. G. Wells, of North-st., Westminster, Civil Engineers. Improvements in constructing breakwaters and other similar structures.

2986. J. F. C. Heyne, of Antwerp. Improvements in railway chairs and rails, and in the mode of fixing the same.

2987. T. Bell, of Plaistow. Improvements in purifying gas.

2988. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in stoppering or closing bottles, jars, and other like vessels. A communication from M. Charoblant, of Paris.

2989. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in washing and drying machinery and apparatuses. A communication from S. Charles, of Paris.

2990. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in revolving fire-arms. A communication from L. F. Devisme, of Paris.

2991. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in machines for embroidering. A communication from B. G. Dutel, of St. Quentin, France.

2992. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in machinery for splitting or dividing hides, skins, leather, and other like materials. A communication from F. Martin, of Paris.

2993. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. An improvement in pipes for smoking. A communication from P. F. Varenne, of Paris.

2994. W. Burgess, of Newgate-st., Agricultural Engineer. Improvements in apparatuses for converting reciprocating into rotary motion. A communication from G. Bancker, of New York.

2995. S. S. Bateson, of Bolton-st., May Fair, Barrister-at-law. Improvements in generating steam.

2996. J. Knowelden, of Southwark, Engineer, and R. D. Edwards, of Upper Belgrave-pl. Improvements in hydraulic engines and apparatus connected therewith.

2997. J. W. Duncan, of St. John's Wood, Gentleman. Improvements in or connected with appliances for transmitting or conducting signals or action by electricity or magnetism, and in the method of testing insulating materials, combinations, or structures, for conducting electricity, and in treating malconstructed or invalid electric telegraph cables, and in utilizing parts of certain cables, or the application otherwise of such structures, and in certain insulating compounds, and in the apparatus and machinery used in connection therewith.

Dated December 31, 1858.

2998. J. H. Johnson, of Lincoln's-inn-fields. Improvements in the permanent way of railways. A communication.

3000. H. Robin, of Nantes, France. Improvements in reaping machines.

3002. T. Z. L. Maurel, of Paris, Civil Engineer. An apparatus protracting indefinitely the working of any mechanism set in motion by springs, more generally applicable to clock-making.

3006. L. A. Normandy, of Judd-st. A new system of shaft tugs. A communication.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this magazine from official copies supplied by the Government, and are therefore the property of the proprietors of the Magazine. Other papers are hereby warned not to produce them without acknowledgment.

STEAM ENGINES, &c., 1017, 1096.

BOILERS AND THEIR FURNACES, 1026, 1033.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1116, 1130.

SHIPS AND BOATS, including their fittings, 1098, 1118, 1127.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1093, 1104.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1078, 1079, 1083, 1119.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1101, 1106, 1112, 1113, 1115, 1120, 1122, 1125, 1129, 1135, 1139, 1141, 1142, 1144.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*

LIGHTING, HEATING, AND VENTILATING, 1088, 1097, 1109, 1126, 1133.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1081, 1085, 1086, 1093, 1095.

METALS, including apparatus for their manufacture, 1094, 1100, 1102, 1111, 1114, 1134.

CHEMISTRY AND PHOTOGRAPHY, 1103, 1107, 1110, 1117, 1123, 1128, 1136, 1138, 1143.

ELECTRICAL APPARATUS, 1090, 1099.

WARFARE. *None.*

LETTER PRESS PRINTING &c., 1121, 1137.

MISCELLANEOUS, 1080, 1082, 1084, 1087, 1089, 1091, 1092, 1105, 1105, 1124, 1131, 1140, 1146.

1078. R. HISLOP, jun. *Improvements in machinery or apparatus for dressing or cleansing and separating grain and seeds.* Dated May 13, 1858.

This consists of a horizontal cylindrical screen, into one end of which the grain or seeds are fed for being dressed. Within this screen is an Archimedean screw revolving independently. The screen is made with fine perforations at the end where the grain or seeds are supplied, and the interstices increase in coarseness along to the other end. Beneath the screen are four receivers, into which the screened matters fall. Into the first the dust, mustard seed, and other matters fall, the second receives the worthless grain, the two last receivers receive the grey and good grain, whilst the stones and large foreign bodies pass out at the open end of the screen. As the grain leaves the screen it is received into two separate conductors, each fitted with an adjustable weighted valve that spreads and regulates the downward supply of the grain. The two last receivers are so disposed that all the good grain from both of the last compartments is deposited in one receiver, whilst all the grey or inferior matters from both compartments are delivered into the other receiver. As the grain falls from these two last compartments it is met by an air blast which acts in concert with two endless cloths or screw traversers beneath. These are so arranged that whilst the good grain from one compartment falls directly into its receiver, the good grain from the other compartment is traversed off into the same receiver, and similarly the grey from both compartments is delivered into one receiver by the same general action. *Patent completed.*

1079. A. M. DIX. *Certain improvements in the process of brewing or obtaining decoctions, and in apparatus connected therewith, which apparatus is also applicable to condensing, refrigerating, or other such like purposes.* Dated May 13, 1858.

This consists, 1, in the use of a condenser or refrigerator in connexion with the closed boiling pan or vessel, to prevent the escape of the effluvia during the boiling of the hops, &c.; 2, in the use of a condenser or refrigerator as applied to the boiling of any other liquid when necessary to boil in vacuo or under the ordinary boiling point of such liquids, whether aromatic or not; 3, of a coil of piping placed between two cylinders or drums, the inner one least in diameter, leaving only sufficient space for the coil of piping to be fixed between the cylinders, and so as not to come into contact with either cylinder, the method of condensing being to pass the steam, &c., over the coil of piping and between the two cylinders in thin streams, and to assist the passage of the steam, &c., by an agitator or propelling fan placed above and within the condenser, a stream of cold water passing simultaneously through the coil of piping, the tube or pipe which conveys the stream and aroma to the top of the condenser or refrigerator terminating in the closed vessel used for brewing or boiling. The reversing of the passages of the hot and cold streams renders the same apparatus available for boiling purposes. *Patent completed.*

1080. F. A. DELIRY. *An improved mechanical kneading trough.* Dated May 13, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1081. A. WOLFF. *Improvements in musical instruments.* Dated May 13, 1858.

This relates to a musical instrument in which a key board and action serves for acting on proper strings (named "independent pedallier") its key board being formed of pedals on which the performer plays with his feet. It may be annexed to any piano. The object of the pedallier is, 1, furnishing to organists the means of exercising themselves in playing the pedals; 2, to facilitate the performing of music written for the harpsichord with tirasse pedal arrangement, or for pianos to which artists have sometimes annexed such tirasse pedal arrangement; 3, to give to the bass notes of the piano the vibrations and fulness of tone required for aiding vocal music of some magnitude. *Patent completed.*

1082. H. HYDE. *An improved mode of, and improved apparatus for manufacturing oils.* Dated May 13, 1858.

This invention has for its object the prevention of undue elevation of temperature at the moment of decomposition by acting on, in succession, layer after layer of the body subjected to heat at the lowest possible temperature, and by the avoidance of the elevation of temperature arising from the action of masses at the same moment; this is effected without applying heat externally to the vessel. *Patent completed.*

1083. J. GARDNER. *An improvement in chaff-cutting machines.* Dated May 13, 1858.

This invention is described and illustrated at p. 42 of our last Number. *Patent completed.*

1084. F. WARREN. *Improvements in the construction of stands for telescopes and other instruments.* Dated May 14, 1858.

The inventor forms of iron, &c., discs or plates, and manipulates their surfaces and centres as that they shall work freely, steadily, and smoothly upon or into each other; and of these plates or discs coupled together he forms the various movements required for the telescope or other instrument. *Patent abandoned.*

1085. J. COLGATE. *A "pipe case handle" for walking sticks, canes, riding whips, and umbrellas.* Dated May 14, 1858.

According to this invention a piece of ivory, bone, hard wood, &c., is turned in the form of a handle; the handle cut into two parts and hollowed out the proper size to admit the bowl of a tobacco pipe; when hollowed out the two parts are attached by a hinge, not observable under the handle, and fasten (enclosing the pipe bowl) at the back of the handle with a catch spring so as to form a handle. *Patent abandoned.*

1086. S. CARPENTER. *Improvements in escapements for watches and other timekeepers.* Dated May 14th, 1858.

This consists in the use of a horizontal escape wheel with three rows of teeth, of which two rows of vertical teeth are so arranged that the stuff which carries the pallets can have its bottom bearing between them so as to allow a tooth on each row to act alternately on the pallets. By giving a double action to the pallets, the watch, &c., is prevented from setting by a sudden jerk, as a tooth of one or other of the rings will always come at once into action on its corresponding pallet. *Patent completed.*

1087. D. DICK. *Improved cushions for trusses and other similar uses.* Dated May 14, 1858.

This consists in substituting a small bag of caoutchouc or other suitable material, filled with air in lieu of mocmain, or any of the materials now in use. *Patent abandoned.*

1088. W. E. NEWTON. *Improvements in the construction of lamps.* (A communication.) Dated May 14, 1858.

This relates principally to lamps fed by oil having a high equivalent of carbon, and consists in forming the lower part of the flame or current of fresh air so that the oxygen therein contained shall be brought immediately in contact with the carbon the moment the degree of temperature of the latter is sufficiently high to promote combustion. *Patent abandoned.*

1089. G. F. CHANTRELL. *An improved waterproof lithic paint.* Dated May 14, 1858.

This composition may be made by taking, say, 2 parts (by weight) of the liquid silicate of soda, or silicate of potash of commerce sp. gr. 1·200, 1 part of common chalk reduced to a fine powder, to which is added 1 part of china clay, also reduced to a fine powder, to which may be added a little cheese or milk, or other matter comprising caseine; the chalk or the china clay may be used solely. The ingredients are intimately mixed. This composition may be coloured any tint by adding colouring matter. The composition is then put into close vessels until required for use, when it is applied in the same way as common paint. *Patent abandoned.*

1090. J. MACINTOSH. *Improvements in insulating telegraphic wires.* Dated May 14, 1858.

Here the patentee laps round the wire a yarn made from gun cotton or other fibre similarly prepared, and then subjects the coated wire to the action of a fluid which acts as a solvent to the gun cotton, &c., so as to cause it to adhere firmly to the wire; sometimes he dissolves gun cotton, &c. in the solvent before applying it to the coated fibre lapped round the wire, and gutta percha, india rubber, &c. may be added to the solution. In this manner a coating of collodi n is given to the wire, which is impervious to moisture. Over this coating, or sometimes to wire not so prepared, he applies a coating of india rubber, and submits the wire so coated to the action of sulphuric acid, or of chloride of sulphur, and a solvent, by which the coating will be so changed as to be no longer liable to be injured by tropical heat. To apply the coating of india rubber he uses grooved rollers. *Patent completed.*

1091. L. PETRE. *Improvements in the application of glass to ornamental and useful purposes.* Dated May 14, 1858.

This consists in the use of glass ornamented or prepared on the one side, the ornament, &c., being visible through the glass. On the ornament or preparation the inventor lays a

Digitized by Google

coat of paint, and when dry a coating of copal or other suitable varnish, which he sprinkles, by a sieve, with sand. He then lets the whole dry and afterwards applies a substance of cement over the entire surface, to which it adheres and becomes as one solid piece with the glass. *Patent abandoned.*

1092. J. H. JOHNSON. ***Improvements in the construction of artificial legs and feet.*** Dated May 17, 1858.

Here a lateral and diagonal flexion of the foot of the ankle joint is provided for as well as the ordinary forward flexion, by connecting the foot to the leg by two sets of cords and springs in combination with a universal or ball and socket joint. *Patent completed.*

1093. D. W. HAYDEN. ***Improvements in boilers for agricultural and other purposes.*** Dated May 17, 1858.

This invention is not described apart from the inventor's drawings. *Patent completed.*

1094. J. and W. ALLEN. ***Improvements in the treatment of iron and copper pyrites and in apparatus for same.*** Dated May 17, 1858.

This consists, 1, in applying atmospheric air by a downward draught to the mass of iron or copper pyrites under treatment for the manufacture of sulphuric acid; 2, in applying a downward draught of atmospheric air within a cupola, &c., for smelting the burned residuum of pyrites containing copper; 3, in the combination of a reverberatory furnace with a kiln, so as to form a furnace for the decomposition of iron or copper pyrites mixed with common salt when worked up into balls, bricks, or lumps, so arranged that the waste heat from the reverberatory furnace shall pass up through the mass of balls, &c. in the kiln; and that the mass of balls, &c. shall pass from the kiln to the reverberatory furnace to be finished. *Patent completed.*

1095. E. TOMUS. ***Improvements in the manufacture of ruche and other trimmings for ladies' apparel, applicable also to making cap fronts and other fluted fabrics.*** Dated May 17, 1858.

This invention is described at p. 47 of our last Number. *Patent abandoned.*

1096. J. WITTENBERG. ***Improvements in motive power engines actuated by air.*** Dated May 17, 1858.

The inventor employs two cylinders, each furnished with two pistons, and piston rods projecting from the two ends. The two pistons of each cylinder are connected by springs which allow freedom of motion, yet are capable of transmitting considerable power from one piston to the other. The two piston rods projecting from similar ends of the cylinders are connected one to either end of a beam, like the beam of an ordinary engine, while the other piston rods are connected with the cranks and shafts to which the power is to be communicated. Two double air-pumps are connected and worked by the beam, each placed as close as possible to its respective working cylinder. *Patent abandoned.*

1097. W. H. BAGNALL. ***Improvements in stove grates.*** Dated May 17, 1858.

The patentee claims, 1, the construction of stove grates described, whatever the shape or configuration given to the air chamber and ornamental parts thereof. 2, the use of distinct separate and moveable lustres, reflecting prisms or radiating surfaces whether of crystal or other glass or other material, mounted, secured, or held in suitable cells, recesses, or frames, for receiving and holding them in stove grates and their accessories. 3, the combination of an air chamber projecting before the line of the stove-front plate, and above and surrounding the fire-grate, with an ash pan as described, whether the moveable reflectors and the radiators and the hearth plate herein described, or either of them, be used in combination therewith. *Patent completed.*

1098. W. RAYMOND. ***Improvements in life rafts.*** Dated May 17, 1858.

This invention will be described in our next Number.

1099. C. W. HARRISON ***Improvements in obtaining light by electricity.*** Dated May 17, 1858.

This invention is described at page 48 of our last Number.

1100. S. HILER. ***An improved method of coating or amalgamating iron with silver, copper, brass, or other metals, or alloys of metals.*** Dated May 17, 1858.

This consists in forming a surface of brass or other ornamental metal on iron or steel as follows:—The inventor takes a sheet, bar, or block of wrought iron (or steel) and cleans the surface on one or more sides, and heats the same, and while heated casts on to the said surface or surfaces the brass, &c., and the union may be accelerated by the use of borax, or other flux, or the coating metal may be united to the iron while the latter is in a state of fusion, and the brass, &c., is to bear the desired proportionate thickness to that of the iron. The combined metals may be then rolled down to the desired shape or thickness, or cut out or made up into any articles for which the same may be adapted. *Patent abandoned.*

1101. H. CURZON, jun. ***Improvements in preparing printed yarns.*** Dated May 17, 1858.

This relates to the process of steaming printed yarns for fixing the colours, and has for its object the dispensing with the immediate covering of the yarn, namely, the upper layer of hulls or cut straw, and the cocoa-nut fibre materials. The patentee causes a coarse thick material, by preference of cotton or wool, to be attached to the under side of each tray, sufficient space being allowed between the material and the tray to ensure ventilation, and thus to facilitate the evaporation of that moisture which the material may have gained from condensation of steam when the tray is removed from the steam chamber. He dispenses with the moveable horizontal bars, and furnishes each tray with elevated ends, which, projecting sufficiently above the level of the yarn in the tray, support the tray above from pressure on it. The trays are in this manner piled one above another in a carriage, and when in the steam chamber, all steam which condenses immediately over the uncovered yarn being absorbed by the coarse material, the yarn is protected from injurious droppings. *Patent completed.*

1102. S. HIGGS, jun. ***An improvement in separating or precipitating copper from water having it in solution.*** Dated May 17, 1858.

The water is placed in tanks, together with scrap iron, and the water is heated by steam or otherwise, it being preferred to employ jets of free steam. *Patent completed.*

1103. R. IMEARY and T. RICHARDSON. ***Improvements in roasting small or disintegrated pyrites.*** Dated May 17, 1858.

The patentee claims in the heating of small pyrites, the use of several flats in the same furnace, or of several separate furnaces so worked together as to secure a regular supply of sulphurous acid, and by such treatment the residuum is rendered commercially useful. *Patent completed.*

1104. W. J. HIXON. ***Improvements in the construction of reaping and mowing machines, and in the form or shape of the knife or knives to be used in connection therewith.*** Dated May, 1858.

These consist, 1, in forming the bar which carries the knife or knives of such machines in a bent or slightly circular form, so as to suit the use of the course of the land over which they have to pass, and thus prevent the knives from being injured by coming into contact with the centre of the land. 2, in using circular knives having either a rotary or reciprocating motion, that is, having a continuous motion in a given direction, or a to and fro motion varied according to suit circumstances, and also to suit the size of the knife or knives used. 3, in constructing at the back of the machine a pan or metal frame which will lay the crops cut by the knives (after they have fallen upon a revolving apron, and are delivered into the said pan) in a suitable way for gathering them. 4, in using the knives having a circular or to and fro motion applied to the straight bar as at present used, the bar itself being constructed either to move with the knives fixed upon it, or the knives being made to move, the bar being in that case stationary. *Patent abandoned.*

1105. J. HIGGINS. ***Improvements in preventing explosions in mines, and in the machinery or apparatus employed therein.*** Dated May 18, 1858.

The inventor constructs a boiler and furnace to generate steam, and places it in any convenient position in the workings of the mine; to this boiler and furnace he attaches piping, which he conveys through the mine, and secures it near the roof. At certain distances he fixes taps, plugs, valves, &c., in the said pipes for letting off steam wherever there is foul air or gas accumulating, so that the steam will mix with the gas, and destroy its dangerous effects. He constructs the boiler and furnace in the shape of a tubed boiler, but he makes the furnace of two or more hollow shelves with vertical tubes, larger in diameter in the top shelf than the next under it, decreasing in each succeeding shelf, so that the fire being made in the top part of the furnace, it will fall through the vertical tubes to the lower part of the furnace in succession, according to the number of shelves or compartments in the furnace. *Patent abandoned.*

1106. J. MALLISON, jun. ***Improvements in the process of, and in the machinery or apparatus for dyeing yarns.*** Dated May 18, 1858.

This relates more particularly to the dyeing of yarns in the "cop," but is equally applicable when the yarn is in the "hank" or "bundle." It consists in dyeing yarns in vacuo, as follows:—The yarn is placed in a chamber or receptacle in connexion with an arrangement of pumps for extracting the air therefrom, and when the air has been sufficiently exhausted from the chamber containing the yarn, and a vacuum obtained, the dyeing liquid is to be admitted to the chamber until full, by which means the yarn will become thoroughly impregnated with the dyeing liquid. *Patent abandoned.*

1107. A. A. CROLL. ***Improvements in the treatment of sulphate of alumina, and in obtaining alum.*** Dated May 18, 1858.

These relate to preparing uncrystallised sulphate of alumina. In the preparation of sulphate of alumina the patentee employs as small a quantity of acid (oil of vitriol) as possible, and he then neutralises any remaining free acid as well as decomposes any salt of iron which it may contain by adding to the preparation soda or potash in an alkaline state, and he prefers to add such alkali in proportion equal to one-fifth of the resulting quantity obtained. Heretofore alum has been produced by a combination with the sulphate of alumina, of either sulphate of ammonia or of sulphate of potash, in certain proportions adapted to produce the best crystals. The patentee substitutes for the sulpbate of ammonia or potash sulphate of soda as a much less costly article, and only uses a small proportion of the sulphate of ammonia or potash. In place of the quantity of sulphate of ammonia or potash usually employed, he uses a proportion of sulphate of soda equal to about one-fifth part of such quantity, adding thereto four-fifths or thereabouts of sulphate of ammonia or potash to make up that quantity. *Patent completed.*

1108. E. C. BROCHAND. ***A travelling mill and improved millstone, part of the invention being applicable to other apparatus turned or worked by horses.*** Dated May 18, 1858.

This mill is mounted on, or combined with, a carriage, that it may travel about from place to place; it is principally intended to be actuated by a horse moving round it. The carriage supports a bolter, as well as the millstones, &c.; a bran box and tool case may also be mounted thereon. The millstones are formed with curved and straight master and guide furrows, leading into one another, whereby a large amount of work, and a better circulation of air, may be obtained. To prevent jerks, shocks, &c., motion is transmitted from the driving-shaft to the driving or main wheel by a pressing or friction-plate wheel or cone mounted on the shaft, and so adjusted as to press on the main wheel just sufficiently to drive it, while it will only slide on its surface without moving it in case of shocks, jerks, &c. This friction-plate is so mounted that it may rise and fall on the shaft while turning with it; it may lie flat on the main wheel, or fit into it by feather and groove, or other adjustment. A pawl is attached to the pole or perch taking into the teeth of a wheel fixed on the shaft, so as to drive it and the shaft when the horse goes forward, but not when it walks backward. The ground matters may be directed into and out of the bolter by guide-screws, &c., actuated by the driving shaft. *Patent completed.*

1109. S. HIGGS, jun. ***Improvements in miners' safety lamps.*** Dated May 18, 1858.

To each lamp an air vessel is applied, in which air is condensed by a suitable pump or apparatus; a stop cock or valve is also applied to regulate the passage of the air from the vessel to the wick of the lamp. By these means, when by reason of the bad atmosphere of a mine the flame of a lamp decreases, it may be improved by allowing the condensed air in the air vessel to flow therefrom to the wick, and the flame will be considerably improved, notwithstanding the lamp may continue to be exteriorly surrounded with the bad air of the mine. *Patent completed.*

1110. G. M. CASENTINI. ***The manufacture of a solution for mixing with or guaging plaster of Paris (or any plaster having sulphate of lime, or any similar substance for its base) so as to produce a hard and dense composition, the hardening or setting whereof may be retarded and regulated by the person using the same.*** Dated May 19, 1858.

The inventor takes borax of commerce, and, having ground it very fine, places a certain quantity of it in a vessel. He then pours in water in the proportion of one and a half gallons for each pound of borax. The contents of the vessel are then boiled and kept stirred, and maintained at the boiling point until by evaporation they are reduced to a saturated solution of borax. The solution is then allowed to cool, when it is bottled off, and in that state kept until it is required for use. *Patent completed.*

1111. J. BROWN. ***Improvements in the manufacture of iron, and in rolling iron and steel, and in machinery to be employed therein.*** Dated May 19, 1858.

These consist in the use of mechanical puddles or stirring and percussive instruments for effecting the agitation of iron while in a liquid or semi-liquid state in the puddling furnace, and for squeezing and fashioning the ball of iron in a heating furnace prior to the action of the hammer or rolls. Also, of machinery by which a ball or bloom is rolled and reduced to a puddled bar. These several parts of the invention are not described apart from the drawings. *Patent completed.*

1112. W. WALKER. ***Improvements in the manufacture of needles.*** Dated May 19, 1858.

The object here is to raise a portion of the metal in front of the eyes of needles on that side of the eye which is towards the point, by so forming or shaping the dies that a blow from a pair of them will form a groove somewhat like an elongated horse shoe, and raise the metal within it in front of the eyes of the needles. *Patent completed.*

1113. M. MACNAUGHT and W. R. CRITCHLEY. ***Improvements in the manufacture of copper or other metallic rollers or cylinders for printing fabrics, and in apparatus connected therewith.*** Dated May 19, 1858.

This consists in forming the ends of the cylinder thicker than the body thereof, and further strengthening the rollers by ferrules, rings, or ribs, either made out of the same solid metal or otherwise secured in the cylinder. And also in the use of a mandril having a coil of horizontal ribs or vertical rings thereupon to obtain a lighter mandril, which is equally applicable to all cylinders; and the cylinders may be used either with or without this form of mandril. *Patent completed.*

1114. J. MAUDSLAY. ***An improvement in the manufacture of iron, and in the furnaces employed therein.*** Dated May 19, 1858.

This consists in imparting motion to molten iron by inclining the bed of the furnace containing it, and causing the said bed to rotate by any suitable motive machinery, in order to improve the tenacity and fibrous quality of the iron, by mixing or agitating it, and thus facilitating the escape of its gaseous impurities. *Patent abandoned.*

1115. J. BOTTOMLEY and A. H. MARTIN. ***Improvements in means or apparatus employed in weaving.*** Dated May 19, 1858.

These relate, 1, to giving motion to rotary shuttle boxes or series of shuttle chambers capable of rotating upon an axis of motion, as also to other series of shuttle boxes capable of moving, in order that any one of the series may be brought into a line with the lay to effect change of weft; 2, to working the levers for sliding the stud wheels from jacquard apparatus employed to work the harness of the loom; 3, to another method of giving motion to rotary shuttle boxes; 4, to holding the series of boxes in position when a selection has been made, and for releasing the same for a fresh selection: 5, to governing the order of motion to a series of shuttle chambers from jacquard apparatus employed to work the harness of the loom; 6, to effect changes in the order of lifting and lowering leaves of heddles, so to change from plain to satin or twill or otherwise; 7, to operating the selvage threads of adjoining selvages of fabrics woven side by side in one piece to be separated afterwards by cutting up and thereby forming distinct breadths; 8, to operating the slay or reed. *Patent completed.*

1116. G. M. MILLER. ***Improvements in the joints of bridge rails for railways.*** Dated May 19, 1858.

These chairs are made with two jaws which project over the flanges of the rails and with a central ridge, which enters the hollow under the rails. This ridge prevents the ends of the rails from shifting laterally, and metal keys driven in between the flanges and the jaws of the chair prevent them from moving vertically. *Patent abandoned.*

1117. C. M. KERNOT. ***Improvements in distilling shale, boghead, and other mineral matters.*** Dated May 19, 1858.

The upper part of the retort or still is formed with an outlet leading to the condenser, an opening at top with a cover, and also a side opening with a cover. Between the head or top of the retort is a partition, consisting of two perforated plates, between which, when first distilling products from shale, boghead, coal, &c., are placed powdered coke and sand in layers, through which the evolved products pass and are filtered in their way to the head, and thence to the condenser. When redistilling products, such as naptha, oils, hydro-carbons, &c., then the still head is formed at the upper part of a pipe or neck, the lower part of which descends some distance into the retort, but so that

Digitized by Google

such lower end comes above the charge of fluid in the retort. Around the upper end of this neck or pipe is formed a gutter, into which the condensed products in the head descend, and are thereby prevented flowing back to the retort, but are carried off with the gases or vapours to the condenser. In the pipe or neck is placed a partition consisting of two perforated plates, between which are placed matters suitable for acting on the passing products in a chemical or mechanical manner, so as to filter such products to arrest impurities and produce chemical changes. The matters which are generally used are black oxide of manganese, sulphate of iron, chlorate of potash, bichromate of potash, and others. *Patent abandoned.*

1118. W. E. NEWTON. *Improvements applicable to certain descriptions of marine engines, and in the mode of mounting paddle wheel shafts.* Dated May 19, 1858.

This consists in mounting the propeller shafts, and with them the paddle-wheels, so as to render them moveable in a vertical direction, to admit of regulating their "dip." The arrangement of the engine is also different from ordinary marine engines in consequence of the paddle-wheel shafts being made moveable. *Patent completed.*

1119. W. F. SNOWDEN. *An improved construction of chaff and litter cutting machine.* Dated May 19, 1858.

The object here is to permit of chaff and litter, or long stuff, being cut by the same machine. The inventor modifies his well-known chaff cutter in some of its details. *Patent abandoned.*

1120. W. CLARK. *Improvements in machinery for manufacturing knotted webs or nets.* (A communication.) Dated May 19, 1858.

This relates to a machine for knitting webs or nets with a single continuous thread, and without a break or severing of the thread, the meshes being made and secured by knots. A single thread only is used, which is added to when it is finished, and which by this means makes it similar to webs made by hand. The knots are made by two hooks, and a needle for each one, and also a shuttle, which furnishes thread to all the hooks. The invention is not fully described apart from the drawings. *Patent completed.*

1121. M. HENRY. *Improved apparatus for communicating or transmitting or producing facsimile copies of dispatches, intelligence or messages, or characters, drawings, or devices.* (A communication.) Dated May 19, 1858.

The object here is effected by the agency of currents. There is a manipulator or transmitter and a receptor, the manipulator consisting of a shaft having alternating motion, with a bar resting on it, which at every motion of the shaft is separated from it preferably by a stud on a wheel, and is fitted with a pipe or stylus in direct communication with the battery, and moving on a plate on which the despatch has been written in non-conducting ink. The receptor, set in motion similarly to the manipulator, is provided with an electro-magnet acting on a moveable piece or lamina, which is attracted each time a magnetic current passes. This lamina has, or ends in, a pen or pencil which traces the characters, &c., transmitted on common paper. As soon as the manipulator stylus begins to move on the plate, a magnetic current is established, and the electro-magnet allows the lamina to fall with its point on the paper and mark on it. *Patent abandoned.*

1122. J. HESFORD. *Improvements in the construction of stretching machines for cotton and other woven fabrics.* Dated May 20, 1858.

This relates to the stretching machines applied to bleachers' and other mangles, and to drying and other machines for widening the fabric. These machines consist of several ribbed slides, placed around an axle, and furnished with diagonal discs to move the slides to and fro in the direction of the axis. The invention consists in making each of the diagonal discs with an internal groove, and in applying anti-friction bowls to the slides; these bowls enter in the grooves; or the diagonal discs may be without grooves, and an anti-friction bowl applied to each side of the disc. It also consists in making the guides of the slides of separate pieces, to facilitate repairs. *Patent completed.*

1123. M. BRUN. *Improvements in dyeing.* Dated May 20, 1858.

This relates to the dyeing of animal and vegetable fibres, yarns, or stuffs, and consists in adding to the dyeing vats a liquid or compound which keeps the vats much longer fit for dyeing than hitherto, permitting, at the same time, alterations in the colours, and giving rise, also, to much faster dyes, thus allowing the use of pigments of a cheaper nature, or in less quantity than was hitherto required for obtaining the same shades. The liquid is obtained by dissolving grain tin in nitric and muriatic acid, to which are then added sulphuric acid and sulphate of zinc, or other salt acting in a similar manner. *Patent completed.*

1124. A. F. COSSUS. *Improvements in treating oils and fatty matters.* Dated May 20, 1858.

This relates to a former patent, dated 21st May, 1855, and consists in submitting fatty matters to the action of vegetable or mineral black, whereby they will be purified and bleached. The blacks which the inventor employs are schists, very perfectly carbonised. He sometimes employs a black composed of argillaceous or aluminiferous earth, to which may be added from 5 to 10 per cent. of vegetable or mineral tar, or some fatty matters. These ingredients may be carbonised in retorts, as in the case of schists, bones, &c. Or a black may be prepared by carbonising fossil calcareous phosphates, with the addition of tar or fatty matters. To produce the desired effect, the mass should be reduced to fragments of about the size of millet seed, and the dust or flour carefully removed therefrom. The fatty matter is placed in a boiler, and to it is added about 3 per cent. of the prepared blacks in the form of small grains. The temperature of the mass is to be raised by steam or otherwise, and to be kept agitated for about an hour, when the fatty matter may be drawn off and filtered, either once or twice, through a bed of white sawdust and a bed of prepared black. *Patent abandoned.*

1125. H. BRIERLY. *Improvements in mules for spinning.* Dated May 20, 1858.

This refers to two previous patents of the patentee, dated 2nd Nov., 1855, and 22nd March, 1856, and is not described apart from the drawings. *Patent completed.*

1126. J. COPCUT. *An improvement in preparing materials employed to obtain light when using oxygen and hydrogen gases.* Dated May 20, 1858.

The gypsum or other material used is raised to, and retained for a time at a red heat in a crucible, in which a small quantity of sulphur is introduced. *Patent completed.*

1127. J. BOYDELL. *Improvements in machinery for propelling vessels.* Dated May 20, 1858.

Here the crank shaft is caused to rotate by engines worked by steam, and two additional steam cylinders are used, each having its piston, piston-rod, and connecting rod, and these additional steam cylinders are constantly open to the steam boiler, so that the steam may pass freely to and from the cylinders and the boiler; other parts are included. *Patent abandoned.*

1128. R. A. BROOMAN. *A method of, and apparatus for purifying sulphuret of carbon.* (A communication.) Dated May 20, 1858.

This consists in bringing sulphuret of carbon in the state of vapour or gas in contact with water. The apparatus consists of a box fitted with perforated plates, which project alternately from opposite ends of the case, nearly across it. The perforations are filled with cotton, sponge, pumice-stone, &c., which is kept wet. The sulphuret is admitted at the bottom of the perforated plates, and in its ascent travels in a zig-zag course towards the top. The rectified sulphuret, being heavier than water, falls into a receiver at the bottom. The condensing water is carried off through a bent pipe when it attains a given level in the receiver, and the sulphuret is drawn off by a stap. *Patent abandoned.*

1129. T. SLITTLE. *Certain improvements in machinery or apparatus for preparing, slubbing, and roving cotton and other fibrous materials.* Dated May 21, 1858.

This consists in making the balance-leg of a "single presser flyer" of a solid rod, round in form, which shape will give additional strength to the flyer, and render it more steady in its revolutions. *Patent abandoned.*

1130. J. C. BRANT. *Improvements in the permanent way of railways.* Dated May 21, 1858.

This relates to a former patent, dated 12th June, 1855, and consists in the addition of a new railway sleeper; of improvements in rails, also, in using cork packing. The sleepers may be formed of potter's clay, refuse of glass works, or plastic clay in combination with plumbago, oxide of iron, manganese, smith's ash, steatite, silica, cements, slag dust, &c. These sleepers may be shaped while the materials are in a plastic condition, and when formed undergo the process of kiln-drying, or burning. They may be formed with or without the chair attached. One of the improved rails is composed of wood and iron, the wood forming the interior, and being slightly raised. The other rail is of metal only, and is a single-headed rail of a V pattern. *Patent completed.*

1131. F. C. BAKEWELL. *Improvements in machinery for making bolts.* (A communication.) Dated May 21, 1858.

The principle of action of this machinery consists in bringing converging dies to press repeatedly and simultaneously against the heated head of the bolt, each simultaneous pressure of the dies being preceded and followed by blows from a swinging hammer fixed to the machine, and actuated by it. *Patent completed.*

1132. M. HENRY. *Improvements in the manufacture or preparation of ink and paper to adapt them for copying purposes, in preserving food, skins, and hides, in rendering lint, vesicatory paper, and textile fabrics absorbent, and in treating mortar, cement, and other matters, in order to keep them in a damp state.* (A communication.) Dated May 22, 1858.

The patentee claims the application of glycerine for obtaining copies of writings, by preparing either the ink or the paper with glycerine. 2, the application of glycerine for preserving food, skins, and hides, for keeping cement, mastic, mortar, paste, and other matters in a damp condition, and for rendering vesicatory paper, lint, and textile fabrics absorbent. 3, preparing ink and paper for enabling copies or impressions to be taken. 4, the mode of rendering copying paper better adapted for the taking of copies by glazing, pressing, or satining it. 5, the preparation of hygrometric ink and paper by glycerine for enabling copies to be taken without mechanical pressure. *Patent completed.*

1133. J. ADAMSON. *Improvements in the manufacture of parts of gas meters.* Dated May 21, 1858.

These relate, 1, to the index, and consist in forming the framing of the index apparatus of hard white metal cast in metal moulds (steel by preference) previously heated. Also in forming part of the tooth gear of such metal. 2, in forming of hard white metal the pins from the guide rods of the valves, and in fixing the stud in a piece of tinned brass. 3, in forming the double crank axis in two parts, with a clutch connexion to the parts outside the valve chamber, so formed that the parts will couple together only in one way. *Patent completed.*

1134. G. F. MUNTZ. *An improvement in preparing yellow metal sheathing.* Dated May 21, 1858.

This consists in rolling such sheathing metal cold after it has been annealed, so that it may be hardened, and applied to a ship's bottom in a hardened state. *Patent completed.*

1135. J. APPERLY and W. CLISSOLD. *Improved machinery for condensing wool and other fibrous substances.* Dated May 21, 1858.

This relates to the rubbing surfaces for condensing the sliver, the object being to secure certainty of action. The rolls the inventors cover with strips of leather coiled helically round a central metal spindle, and arranged so that the thickness of the leather, or the cross section of the grain, will be shown on the periphery of the roll. They also apply to the feed end of the condensing machine a bar for guiding the wool into the bite of the taking rollers, thereby neutralising the tendency which these rollers have when supplied by a diagonal feed to draw the fibres endways into the machine. *Patent completed.*

1136. S. BEYER. *Improved instruments to be used in the sensitizing and developing of photographic plates.* Dated May 21, 1858.

The patentee provides a set of instruments for gripping the plates, whereby they may be transferred from the sensitizing bath to the plate frame of the camera, and again removed therefrom and presented to the developing fluid, without being touched by the operator's fingers. The grippers are not described apart from the drawings. *Patent completed.*

1137. J. SNOLL. *Improvements in the manufacture of paper used for letter-press, lithographic, and copper-plate printing, and for other purposes.* Dated May 21, 1858.

This consists in the introduction of chalk or whiting into the body or on the surface of such papers, which, in the case of printing papers, imparts weight and substance, and tends to render them more opaque. *Patent abandoned.*

1138. W. CLARK. *Improvements in the processes of treatment of peat, and of the hydro-carburets it contains, and in the apparatus for the same.* (A communication.) Dated May 21, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1139. J. ELCE and J. CHAMPION. *Improvements in parts of machinery used in preparing and spinning cotton and other fibrous materials.* Dated May 22, 1858.

Top rollers are usually made with two bosses, and this invention consists, 1, in making one of the bosses with a projecting stud in which the other fits loosely, so that each boss may turn independently of each other. 2, in supplying a loose tube between the two bosses for the weight hook or saddle to bear upon. 3, in making each boss of top rollers with two projecting studs or pivots to which the weight hooks or saddles are suspended. 4, in making the saddle of the weight with projections to hold the single top rollers in their places, and in jointing the saddle to a bar passing behind the rollers. *Patent abandoned.*

1140. P. FERON. *An improved bandage or truss.* Dated May 22, 1858.

The advantage of this truss consists in the fixity of the cushion laterally, and its mobility backward and forward during efforts of nature. The details are not described apart from the drawings. *Patent completed.*

1141. J. RONALD. *Improvements in dressing hemp, flax, and other fibrous materials.* Dated May 22, 1858.

This specification must be consulted; the machinery described cannot well be explained verbally. *Patent completed.*

1142. E. T. HUGHES. *Improvements in machinery or apparatus for embroidering.* (A communication.) Dated May 22, 1858.

This relates to embroidering, so as to introduce the pattern at the same time the fabric is woven, and consists of two frames working invertedly by two springs passing over each other under a double pulley, of a diameter proportioned to the number of teeth in a wheel which is fixed to a cross piece adjusted to the batten. The wheel gives motion to the machine by the levers, each having an independent hook corresponding to the jacquard. The frames rest on moveable feet, to which strings are attached with elastic springs to preserve the required tension. To produce the design a number of needles divided into combs are fixed to each of the frames, the needles being supplied with the materials for embroidering. On one side of the batten is fixed an escapement pulley, the other side resting on the wheel, rotary motion being given to the wheel by the pulley, and two small rollers, containing the materials to be embroidered, are fixed behind the batten on a suitable frame. *Patent abandoned.*

1143. E. T. HUGHES. *Improvements in machinery or apparatus serving the purposes both of saponification and of decomposing neutral fatty substances into fatty or oily acid and glycerine.* (A communication). Dated May 22, 1858.

By this invention, neutral fatty substances, whether animal or vegetable, produce fatty acid and glycerine, by putting them in contact for some hours at a high temperature: 1, with ordinary water; 2, with water to which is added one or two per cent. of alcohol to facilitate the dissolution of the glycerine; 3, with water and five or six per cent. of the spirits of wine, dissolved very powerfully; 4, with a mixture of sulphur of carbon, the essence of terrebenthine, and the essence of lavender, in equal parts. *Patent abandoned.*

1144. J. FOOT. *An improvement in the manufacture of fringes.* Dated May 22, 1858.

This consists in causing the weft thread to be carried across and be incorporated in both of the warps, only at the alternate motions of the shuttle, the weft threads being securely tied into the heads by being passed to and fro through sheds opened in the one warp, then across to the other warp, and there tied into that warp by passing to and fro through sheds opened into that warp. *Patent completed.*

1145. F. G. UNDERHAY and J. L. CLARK. *Improvements in cocks or taps, and in apparatus for flushing.* Dated May 22, 1858.

Here, means are provided for the passage of water from the face of the valve which closes the water-way, or passage, to the back of another valve or piston, so as to complete, more or less, an equilibrium in regard to the pressure of the water. *Patent completed.*

1146. T. S. CRESSY. *Improvements in apparatus for calculating wages.* Dated May 22, 1858.

Here an endless sheet is used, on which is marked in columns the amounts of wages for a week, days, and hours, and this endless fabric is carried by rollers, so that any one of the columns of figures may be brought into position at a particular part of the frame carrying the combined apparatus. At this part of the frame there are covered openings (generally twelve for the several days and double days of a week, nine for the hours of a day, and three for the fractions of the hours, but these may be varied to serve particular objects). There is also an opening through which can be seen the amount of a week's wages which the column then in position is calculated for. *Patent abandoned*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JANUARY 28, 1859.

SPECIFICATIONS OF PATENTS FOR INVENTIONS.

LOCOMOTIVES, steam-ships, electric telegraphs, and other modern agencies, have so greatly quickened the pace of the world, that scarcely one man in a hundred is able to resist, even for a moment, the general onward tendency, and turn to gaze on "days that are no more." The man of letters or of leisure may find time to do so; the historian and the antiquarian must. But the words of command of the man of business are—eyes front! quick march! Inventors especially are prone—perhaps beyond all others—to press forward, heedless of all but the future. Once visited by an idea new to himself, and full of seeming promise, the inventive enthusiast straightway demands the "provisional protection" which the law holds out to him, and at once rushes forward to squander his capital, or to make his fortune, as the case may be. So little does he doubt the originality of that which, in his own eye, glitters with novel brightness, that he is often guilty, not only of failing to examine if his conception really be as new as it appears to him, but guilty also of accumulating wealth by means of that which was known, and perhaps in use, years before he was born—the fortunate sinner! To the grudging dispositions of some, this gives terrible offence, and they have sought to remedy it by various devices. But it will never be otherwise; nor do we see why it should be. Of course, if an exclusive privilege to use a machine or to apply a process be granted to one man, it must be presumed that the machine or process is not at present in use by another; and if it be, the latter must not have his proceedings stopped or interfered with by the privileged party. But we cannot see that more than this is necessary. This is, however, a subject on which there is much to be said, and which we will not here pursue further.

The object of this article is to inform inventors that if they desire to satisfy themselves respecting the novelty of any invention of theirs, they may do so with greater ease and certainty, and at less expense, than the inventors of any former age. To facilitate their inquiries, the Commissioners of Patents, appointed under the Act of 1852, have done three very important things. First, they have printed and published the specification of every patent granted in England from the earliest times to the present. Secondly, they have commenced, and proceeded a long way with, the printing and publication of a series of small classified volumes, in which the whole of the specifications are abridged somewhat after the fashion of those which we have ourselves been in the habit of publishing for some years. (See "Abridged Specifications of Patents," in the present number.) Thirdly, they have gratuitously furnished their publications to free libraries in Birmingham, Leeds, Liverpool, Manchester, Nottingham, Sheffield, York, and from sixty to seventy other towns in the United Kingdom, as well as to numerous official departments, seats of learning, colonies, and foreign states; and have also established in London a central free library, where they may be consulted daily. The patents under the old law—that is, patents granted from the time of James I. (in whose reign the first grant was obtained), up to October, 1852—number nearly 15,000. The specifications of these are sold to the public at cost price, which, on the average, we believe is about 1s. These are literal reprints of the original specifications themselves, and, although not absolutely free from defects, have certainly been printed with wonderful accuracy. But as these 15,000 would probably cost nearly £1,000, and as they are added to at the rate of about 3,000 a year—involving a further annual expense of about £150 since 1852—the whole of the specifications of existing patents could not be purchased for much less than £2,000. Now, we need hardly say that many a man may have the brains to contrive an invention without having £2,000 to spend in ascertaining if it be new. In order, therefore, that this might not be necessary, the Commissioners took the second step—that of grouping the inventions into classes, and publishing the classified specifications in an abridged form in small volumes. Several of these are already published, and are now before us.* It is impossible to exaggerate their value. The whole of the books whose titles are given below—forming a pile of 12mo volumes, six inches high—may be purchased for about 22s. Taking the volumes singly, their value becomes still more apparent. In the second, for example, the price of which is 5s., we have an outline description of every invention for the improvement of iron and steel patented between the time of Lord DUDLEY—who, on the 21st of February, 1621, obtained the first patent granted for a successful attempt to improve the manufacture of iron—and the 24th of June, 1857. At the foot of each abstract are given references to notices of the inventions which have appeared in the volumes of the MECHANICS' MAGAZINE and other works, and to the reports of law proceedings for infringements, &c. Of course they are but "outline descriptions," and necessarily afford, in many instances, a mere hint only of the invention. The official compilers have manifestly been subject to the difficulty with which we ourselves are but too familiar—that of extracting *any* pith or point from some specifications, either because of the peculiar nature of the inventions, or because extremely ill-drawn specifications are filed by some patentees, and by some individuals who take upon themselves the office of agent for patentees. Let us notice a few examples of the manner in which the authors of these official abridgements have been compelled to pass over some specifications. Of No. 10,805, they merely say, "the invention relates to ores containing copper;" of No. 10,834, "the invention refers exclusively to ores containing tin;" of No. 12,074, "the specification and drawings describe, under eight heads, various improvements in the self-acting steam hammer;" of No. 1,209, (1852), "these [improvements] apply to the process of smelting sulphuret, copper, and other ores;" of No. 754 (1854), "it relates to stamping and washing machinery suitable for working the precious metals;" of No. 2,419 (1855), "the specification and drawings, which require to be consulted, describe an improved arrangement of valves and valve gearing and pistons applied to forge and other hammers worked by elastic gas, steam, or compressed air;" and so on. Some of these are shorter than the abstracts given in our columns when the specifications were filed. We put these facts forward, because correspondents sometimes suppose that our abstracts are briefer than they need be, and because we often feel dissatisfied ourselves when we are unable to give a condensed statement of an invention, and have to refer readers to the specification itself. The fault chiefly lies with those patentees who either file ill-drawn specifications themselves, or permit such to be filed in their names. A mere drawing with references is often deposited as a specification, without any statement of the nature of the invention, or of the manner in which it is to be performed. Such documents are worth nothing, and the patent rights which depend upon them are, of course, worth no more. Specifications of this kind most frequently proceed from foreign sources—sometimes from foreigners who do not understand the English law, but nevertheless act for themselves; and sometimes from foreigners who understand it no better, but nevertheless act for others! We regret to have to add that there are Englishmen who have no more knowledge, and no greater integrity. On the other hand, specifications of inventions are sometimes either so voluminous or so much in detail as to render any brief statement of the invention impossible—or, if possible, unintelligible. On the whole, we believe—and we may say with perfect confidence that we speak from a longer and more arduous experience in this matter than has fallen to the lot of any other person—these "Abridgments" are made with very great care, and are in every respect creditable, in the highest degree, to the Commissioners of Patents, to Mr. WOODCROFT, their Superintendent of Specifications, and to the Department generally.

We have no space left to speak here of the office—especially the library—in which all these publications are prepared. The *Times* lately denominated it a "gloomy office, only fit to be used as a cellar," although it "has a surplus revenue equal to that of some Principalities, and is stored with treasures of such accumulated knowledge and skill as, if once destroyed, could never be replaced." The *Times* did not exaggerate the truth. We can only now ask the Commissioners,—When is the gloomy cellar to be changed for an appropriate building? This question we shall urge upon them on an early occasion.

THE SILVER COINAGE.

THE *Times* of Monday last gives publicity to a letter from "H. F. B." on the silver coinage. This correspondent complains to the Editor of the great journal that many of the shillings, sixpences, and other coins of smaller value, now in circulation, are much the worse for wear. He appears, however, not to be aware that the Bank and the Mint are continually endeavouring to meet and to obviate the inconveniences arising from the incessant and inevitable deterioration of the silver coinage. When the constant moving from hand to hand, from pocket to pocket, and from counter to counter, which the silver family of coins have to undergo is taken into reckoning, it is not strange that they should exhibit the effects of such changings. The sharp edges of the engraving are first taken off by friction, then follow the legend and superscription, and finally the wear "begets a smoothness" which makes their individuality dubious. These are natural results. They are also unavoidable. The newly-minted shilling, with all the bloom of the well-polished die upon its surface, becomes, after a week's contact with the world, dull and spiritless. In a few more weeks, it is found lighter than when issued from the mint, and, in its restless course of existence, must display the effects more and more palpably of the "fast" life it leads. These things are patent to the public, as they necessarily are to those who have to provide a remedy for them. If "H. F. B," in place of writing grumbling letters to the Editor of the

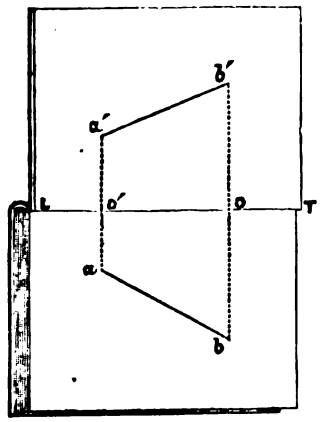
Digitized by Google

Times, would but take up the Commons' annual return of work done, and expenses incurred in producing at the Royal Mint current coins of all kinds for the convenience of Her Majesty's lieges, he would find that £10,000 is expended yearly in the purchase of worn silver, and that the quantity of new florins, shillings, sixpences, and threepences constantly being struck and sent forth to fill the voids created by its withdrawal, is more than proportionate to the occasion. At the Bank of England there is a constant detention of worn-out coins of the kinds referred to, which reach it from the branch banks of the United Kingdom; and, at intervals, when a sufficient accumulation has been made, they are despatched to Tower-hill, and passed once more through the melting-pot, and subjected to such other processes as are necessary for their conversion into new coin. "H. F. B." will thus learn that the constant and irremediable wearing out of the old metallic currency is met by the continual creation of a new, and that the quantity of old *and* new silver coin at present in circulation is greater now than it has been previously in the annals of England. The quotations of the *Times* correspondent from Macaulay as to what Newton and Bacon thought about the currency in their days, are interesting, because the men alluded to were giants in intellect, but they are not at all relevant to the exigencies of the present time.

LAYING-OFF;
OR, THE GEOMETRY OF SHIP-BUILDING.
No. II.

HAVING shown how points and lines may be projected and the positions and directions of plane surfaces recorded upon *two* planes at right angles to each other, we must now point out the means by which these *projections* and *traces* may be recorded on *one* plane—that of the sheet of paper on which we make a projection drawing. We have seen in fig. 2 (page 39) that the perpendicular distances of a' and b' from the axis are equal to the heights of A and B above the horizontal plane. Now if we bear in mind how these points a' and b' have been obtained, and what they represent, we shall know just as much about the heights of A and B if the cover of the book is turned down until it is in the same plane as the first leaf, as in fig. 5, as we should were it held at right angles thereto, as in fig. 2.

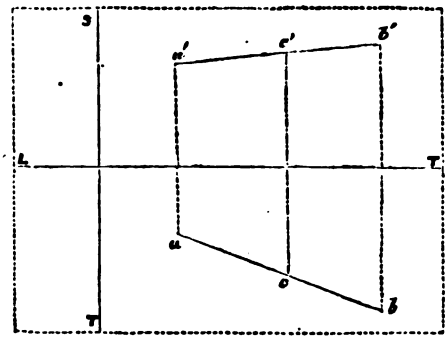
FIG. 5.



Let us suppose, then, that the vertical plane is made to turn about the axis until it comes into the same level as the horizontal plane. The projections (a, a') and (b, b') of the points A and B, and the projections (a, b) (a', b') of the line $A\,B$, will then appear as shown in fig. 5, $L\,T$ being the joint or axis. It must be observed that the projections of any particular point in $A\,B$ as of A will be immediately over each other, so that the line $a\,o'\,a'$ joining a and a' will be perpendicular to the axis.

This will be seen at once if we imagine a plane to be drawn across the two planes of projection in fig. 2, page 39, perpendicular to the axis, and therefore cutting each of these planes in a straight line at right angles to the axis—the two lines meeting in the same point in the axis. Now, it is evident that the *projecting lines* of A in that figure, viz., $A\,a'$ and $A\,a$, will be parallel to this supposed plane, and that therefore the projections a and a' will be at the same distance from its traces as A is from the plane itself. But when the vertical and horizontal planes are brought into the same level as in fig 5, the vertical and horizontal traces of the supposed plane will form one straight line S, T, fig. 6, at right angles to the axis; and as a and a' have been shown to be equally distant from these traces, it will follow that the line joining a and a' is also at right angles to the axis (fig. 6). The same might be proved of the line joining the projections of B, or of any other point, either in the line $A\,B$, or in space. From this

FIG. 6.

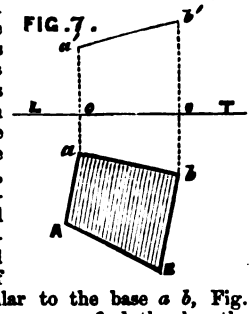


will follow the important fact, that if c is known to be the horizontal projection of a point C in the line $A\,B$, then c', the vertical projection of C, may be found by drawing a line from c at right angles to the axis to meet the line $a'\,b'$. We have shown by dotted lines, in the last figure, the boundaries of the planes of projection, but it will be seen that they answer no end, and may be dispensed with if we are careful to preserve the position of the axis L, T; for the future, therefore, we shall only give the axis, and suppose that all above this line belongs to the vertical plane—all below it, to the horizontal plane.

We shall now proceed to show, as we have promised, that the projections a, b and a', b' record the *length* of the line A, B as well as its position.

Since a and b, Fig. 7, are the horizontal projections of the points A and B respectively, we know that these points lie immediately over a and b, *i.e.*, in lines drawn up from them perpendicular to the paper, so that the line $A\,B$, its projection a, b, and the perpendiculars from A to a and from B to b, form together a four-sided figure, the sides of which are perpendicular to the base $a\,b$, Fig. 2, (page 39); if, then, we can find the lengths of the perpendicular sides, and construct the figure, we shall obtain the true length of $A\,B$. But we have seen before, that the length of the line $A\,a$ is $o'\,a'$, and the length of $B\,b$ is $o\,b'$; construct therefore the four-sided figure A, B, b, a, and $A\,B$ is the length required. It is the same thing as if, keeping $a\,b$, (in Fig. 2) fixed, we had turned the four-sided figure, $A\,B\,b\,a$, down upon the plane, that we might look at it. This operation of throwing the figures down that we may see them in their true shape and dimensions is called *rabatment*, the English of which is "throwing down." As we shall frequently have occasion to adopt this method, we should recommend the reader to be quite sure that he understands it before we pass on. It would be good exercise to

FIG. 7.

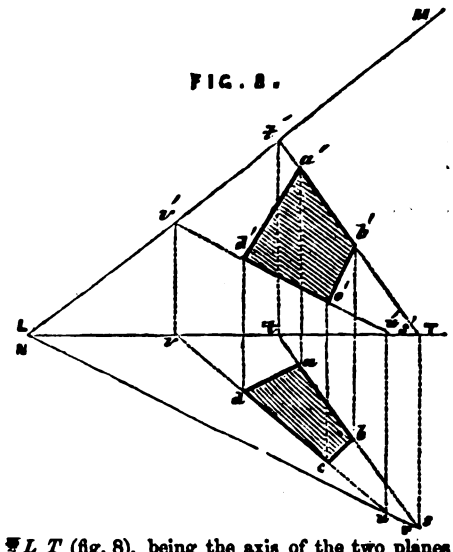


draw fig. 7 on a piece of paper, and to cut with a penknife along the lines $a\,A$, $A\,B$, and $B\,b$; then if the shaded figure is turned up until it is square to the paper, and the paper be bent at $L\,T$ until the vertical plane is perpendicular to the horizontal plane, it will be seen that $A\,B$ is really the line of which $a\,b$ and $a'\,b'$ are the projections.

As we are anxious to proceed to the drawings of a ship, we shall conclude these introductory considerations with a problem which is so far advanced in the theory of projections that we shall lay ourselves open to the charge of incautiousness in taking beginners beyond their depth. We must, therefore, beg them to proceed with care, and to give due heed to every step; and we promise, on our part, that where any explanation is really necessary, in addition to what has been already given, it shall not be withheld.

The problem is—having given the projections of a plane quadrilateral—*i.e.*, of a four-sided figure, find the true shape.

FIG. 8.



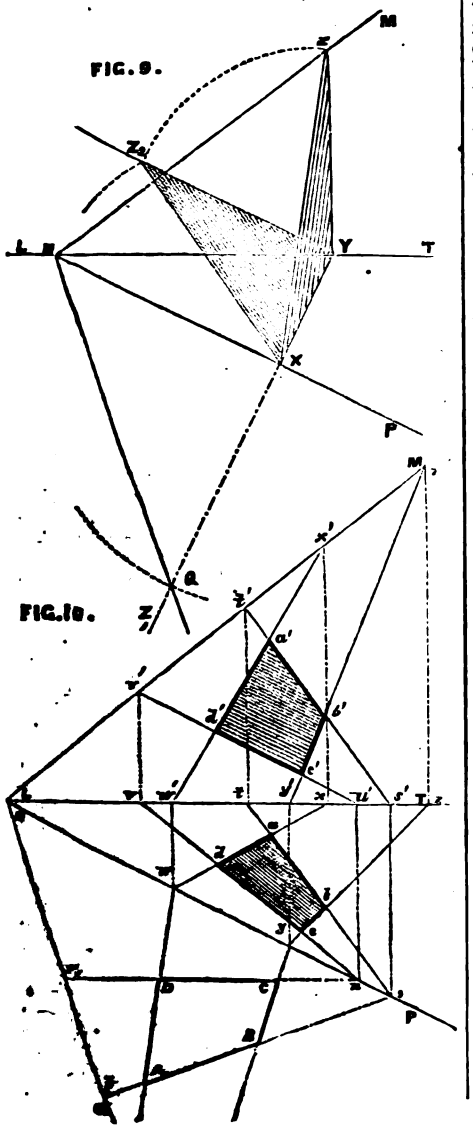
$L\,T$ (fig. 8), being the axis of the two planes of projection, let $a\ b\ c\ d$, and $a'\ b'\ c'\ d'$, be the horizontal and vertical projections respectively of a quadrilateral figure lying in an oblique plane, the position of which is not given. Neither of these projections being the true shape of the figure, it will be necessary to perform a rabatment—*i.e.*, to throw the figure $A\,B\,C\,D$, down upon one of the planes of projection. To do this, we must discover the plane in which the figure is lying, and then turn it about one of its traces until it coincides with the plane of projection. The figure sought may then be drawn upon it. First, to find the plane. Here it may be observed that, since the figure is plane or flat, the plane which contains any two sides of it must contain the whole figure, and that it will be sufficient to discover the plane containing the lines $(a\ b)$, $(a'\ b')$, and $(c\ d)$, $(c'\ d')$. To do this, produce $a'\ b'$ downwards until it meets the axis in s'. Then s' is the vertical projection of a point in the line $A\,B$, the height of which above the horizontal plane is nothing, and which is therefore *in* the horizontal plane. And if s' be the vertical projection of such a point, we have already shown that the horizontal projection s of the same point may be found by drawing a line from s' perpendicular to the axis until it meets $a\,b$—the horizontal projection of the side $A\,B$—produced. s, s' is therefore a point in the line $A\,B$, and also in the horizontal plane of projection, *i. e.*, is the point in which the line $A\,B$ pierces the horizontal plane. This point is called the horizontal *trace* of the line $A\,B$. Again, produce the horizontal projection b, a until it meets the axis in t; then t is the horizontal projection of a point in $A\,B$, the distance of which from the vertical plane is nothing, and which is therefore *in* the vertical plane. The vertical projection of this same point will be t', where a perpendicular from t meets $b'\ a'$ produced;

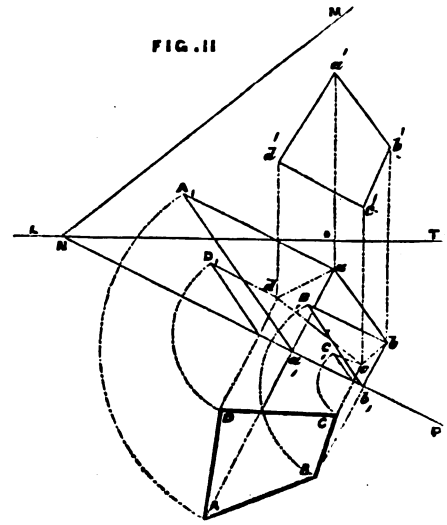
Digitized by Google

(t t') is therefore the point in which the line $A\,B$ pierces the vertical plane, and is called the vertical *trace of* $A\,B$. If the diagram were now bent so that the part above $L\,T$ were at right angles to that below it, it would be seen that a line stretching from s to t' would have $s\,t$ and $s'\,t'$ for its projections. We may find in a similar manner v' and u the vertical and horizontal *traces* respectively of the line ($c\,d$), ($c'\,d'$) or $C\,D$ produced. As we have now found the points in which two of the sides of the figure, when they are produced or extended, pierce the planes of projection, we are able to determine the lines in which the plane containing these sides cuts the planes of projection, for it is clear that the plane must cut the vertical plane of projection exactly where the lines pierce it, so that its vertical trace will be the straight line $M\,N$, passing through the points v' and t'; and that in the same way it will cut the horizontal plane in the line $P\,N$, joining s and u. $M\,N\,P$ will therefore be the plane containing the lines ($a\,b$), ($a'\,b'$) and ($c\,d$), ($c'\,d'$), and also the figure of which they form two of the sides. We have shown the traces $M\,N$, $P\,N$, discovered as just described, meeting in the axis. If in constructing the figure they should be found not to do so, it may be concluded at once that there is an error in the work, for a moment's consideration will show that $M\,N$ and $P\,N$ could not be the traces of one plane unless they met in the axis. Having thus obtained the plane in which the figure lies, we may proceed to *rabat* the portion $M\,N\,P$ included between the planes of projection.

To avoid confusion we will perform this operation in a separate figure, fig. 9, in which $M\,N\,P$ is the plane to be rabatted—suppose about its *horizontal* trace $N\,P$. Our object will then be to discover where the line $M\,N$ would lie if $M\,N\,P$ were thrown down upon the horizontal plane. It is at once obvious that the point N will remain fixed, and that we have only to find where one other point in the line $M\,N$ will be after the revolution. Let Z be this other point. From Z draw $Z\,Y$ perpendicular to the axis, and from Y draw $Y\,X$ perpendicular to $N\,P$ and join $X\,Z$. It will be evident that $X\,Y\,Z$ is a right-angled triangle, the hypothenuse of which, $X\,Z$, is in the plane $M\,N\,P$, and is perpendicular to the trace $N\,P$. Now any line in the plane $M\,N\,P$, which is perpendicular to $N\,P$ *before* the plane is thrown down, must also be perpendicular to it *after* the rabatment. So that after this operation the line $X\,Z$ must lie in the line $X\,Z_1$, drawn from X perpendicular, to $N\,P$ and the point Z will therefore be found in this line, and it only remains to discover how far it is out from $N\,P$. For this purpose we must find the true length of $X\,Z$. This may be done by remembering that it is the hypothenuse of a right-angled triangle of which $X\,Y$ is the base and $Y\,Z$ the perpendicular. Construct, then, such a right-angled triangle on the plane of the paper by drawing $Y\,Z_2$, perpendicular to $X\,Y$ and equal to $Y\,Z$, then $X\,Z_2$ is the real length of $X\,Z$, and the point Z must lie in $X\,Z_1$, at a distance from $N\,P$ equal to $X\,Z_2$ *i. e.*, at Q, found by sweeping the arc $Z_2\,Q$ from centre X. Join N and Q, and the line $N\,Q$ is $M\,N$ rabatted; and $P\,N\,Q$ is the true shape of $M\,N\,P$, the portion of the plane included between the planes of projection. In Fig. 10, we have added to Fig. 8 the line $N\,Q$ thus discovered, and have found the points (w w') and (y y') in which the other sides $A\,D$ and $B\,C$ of the figure pierce the horizontal plane, and which, for the reasons stated with regard to (s s') and (u u') must lie in $N\,P$. Similarly (x x') and (z z') are the points in which these sides pierce the vertical plane.

When we rabat the plane $M\,N\,P$, the points s, u, y, and w, in which the four sides of figure produced meet the horizontal plane, remain fixed, while the points t', v', z', and x' will be found along $N\,Q$, at the same distances as before from N. Therefore, set off these distances and find the points v t, &c. Then, if u and v be joined, the line $G\,D$, of which ($c\,d$) ($c'\,d'$) are the projections, will be a portion of it; and so, also, if s and t be joined, the line $A\,B$, of which ($a\,b$) and ($a'\,b'$) are the projections, will be a portion of it. Similarly join w and the point in $N\,Q$ produced corresponding to x', and we shall obtain $D\,A$; and by joining y with the point corresponding to z', we shall obtain the fourth side, $C\,B$. Thus is discovered the true shape and size of the figure of which ($a\,b\,c\,d$) ($a'\,b'\,c'\,d'$) are the projections.





This problem might have been solved by rabatting each of the points A, B, C, D without rabatting the plane. Fig. 11 shows the mode of effecting this. We know, for example, that if a plane be drawn through the point A, *before rabatment*, and perpendicular to the line $N\,P$, it will cut the horizontal plane in a line $a\,a_1$, and the plane $M\,N\,P$ in a line through a_1, perpendicular to the line $N\,P$. These two lines, together with the perpendicular leading down from A to its horizontal projection a, form a right-angled triangle of the same dimensions as the triangle $a\,a_1\,A_1$, in which $a\,A_1$ is drawn equal to $o\,a'$. If this triangle be now turned edgewise about the point a_1, and perpendicular to $N\,P$ until its hypothenuse reaches the horizontal plane, the hypothenuse will then coincide with the line $a_1\,A$ the distance $a_1\,A$ being set off equal to $a_1\,A_1$, the distance of the point A in its original position from $N\,P$. Proceeding in a similar manner with regard to the point B, *i.e.*, drawing from b, $b\,B_1$, perpendicular to $b\,b_1$, and therefore to the horizontal plane, and setting up on it the height of b' above the axis, we obtain a triangle in which $b_1\,B_1$ is the distance of the *unrabatted* point B above the axis; upon throwing this triangle down we discover the point B. Find in this way, also, the points C and D, join them, and the figure $A\,B\,C\,D$ is the same as that obtained in fig. 10, viz., the figure of which ($a\,b\,c\,d$) ($a'\,b'\,c'\,d'$) are the projections.

SHIPPING STATISTICS.

(*Concluded from page* 43.)

THE test of dynamic merit, as above set forth, based on the mutual relations of displacement, speed, and power, presumes on the net power effectively applied in propelling the ship being always in a constant and known ratio to the gross indicated power.

The inquiry, therefore, so far, is of such a nature as demands professional knowledge and skill in order to determine and discriminate between the merit that may be due respectively to the type of form of the hull, and to the construction of the engines, propeller, and boilers; for a good type of hull, propelled by an inferior construction of machinery and boilers, or an inferior type of hull propelled by a good construction of machinery and boilers may, by the above formula, produce equal results. This committee, however, considers it of vital importance to the promotion of the objects of this inquiry, viz., "the maturing of a system of statistical record conducive to the improvement of naval architecture," that the owners and charterers of ships, and the directors of shipping companies or agents by whom shipping affairs are conducted, should themselves have the means of ascertaining the relative dynamic merits and working condition of their ships without any reference whatever to the professional assistance of builders or engineers, but be enabled to judge for themselves whether the performance be good or bad by reference to the data afforded by their counting-house records; and this desirable object may be at once effected by the displacement of the ship being known, and by substituting in the foregoing formula the consumption of fuel in a given time (say the weight in cwts. (W) consumed per hour), in lieu of the expression for power, and regarding the hull, machinery, and boilers collectively as an integral equipment of which the co-efficient derived from the formula $\frac{V^3 \times D^{\frac{2}{3}}}{W}$ indicates the dynamic condition with reference to the dynamic condition of other vessels tested by the same rule, viz., multiply the cube of the speed by the square of the cube root of the mean displacement, and divide the product by the consumption of fuel per hour expressed in cwts. The quotient indicates the relative dynamic condition of the vessel. For example: A steam-ship (A) performed out and home voyages amounting to 7,200 nautical miles in 652 hours, being at the average speed of 11·04 knots per hour, the consumption of coal was 1,519 tons or 30,380 cwts., being at the rate of 47 cwts. per hour, and the mean displacement was

Digitized by Google

2,934 tons. Hence the co-efficient of dynamic duty indicative of the merits of the performance on this occasion is—

$$\frac{(11{\cdot}04)^3 \times (2934)^{\frac{2}{3}}}{47} = \frac{1345{\cdot}6 \times 205}{47} = 5870.$$

Again, another vessel (B), with a mean displacement of 840 tons, attains on long-continued service the average speed of 12·78 knots per hour, with the average consumption of 50·3 cwts. coal per hour, giving a co-efficient of dynamic duty—

$$\frac{(12{\cdot}78)^3 \times (840)^{\frac{2}{3}}}{50{\cdot}3} = \frac{2087{\cdot}3 \times 89}{50{\cdot}3} = 3693.$$

Thus, in one case (A) the co-efficient of dynamic duty, based on the consumption of fuel, is 5870, whilst in the other case (B) it is only 3693; that is, one cwt. of coal in A performs as much dynamically effective work as is performed by $1\frac{6}{10}$ cwts. in the case of B, a discrepancy which may well induce professional inquiry being instituted by the shipowner, whether the inferior performance of B is occasioned by inferior type of form, or foulness of bottom, or inferior principle of mechanical appliances, or inferior management, or bad coal; for these causes, combined, or indeed either one of them alone, may be sufficient to account for the result.

Now, what are the all-important elements of construction thus proposed to be embraced in public records, and thereby made known to the purchasers and charterers of ships with a view to enable such parties to test the economic working capabilities of ships, so conducive to the reformation above referred to? Why, by the rule above enunciated, the displacement corresponding to the constructor's load draught at which the ship may be tried, and to which approximately, as a general rule, the ship may be loaded, becomes the only item of statistical data that requires to be officially recorded, for the test trial and sea performances of ships, as above shown, will give the capabilities for speed; and the consumption of fuel per hour corresponding thereto will be known from the counting-house ledger.

It is, therefore, suggested that the registration records of every ship give the displacement when the ship is immersed down to some definite line, which may be denominated the constructor's load line.

The assignment of the constructor's load line draught forward and aft, and the corresponding displacement, is all the statistical data that is required to be registered in addition to the details of registration already enforced under the Merchant Shipping Act of 1854, in order to determine the comparative co-efficients, and put the system of practical rivalry hereby suggested into operation, as being the most effective system for inducing improvement in naval architecture.

As regards the existing system of shipping statistics and shipping registration, with reference to its affording data available for promoting shipping improvement, this committee has to observe that, although the aggregate register tonnage of mercantile shipping appears to be a very close approximation to the aggregate weight-carrying capability of the entire mercantile navy, still, when considered in detail with reference to particular ships, it is found that the register tonnage of a ship affords no approximate criterion whatever either of the load displacement or of the weight-carrying capabilities of ships respectively, for, by reference to the Appendix, it will be found that ships are frequently loaded with dead weight of cargo to the extent of double their register tonnage, and the statement shows the following extreme cases of weight-carrying capability with reference to register tonnage:—

Country traded with.	Vessels.	Weight of cargo.	Register Tonnage.	Ratio of Cargo to Tonnage.
		Tons.		
Morocco.....	34	11,576	4,075	2·8 to 1
Tunis	1	780	259	3 to 1
Bolivia	2	2,301	455	5·2 to 1

These cases appeared so remarkable that the committee were anxious to prosecute inquiries with reference to the build and sea performances of those particular ships, and with that view they addressed a letter to the Custom House for the purpose of identifying the vessels thus referred to; but the official fees demanded for responding to such inquiries, put it out of the power of the committee to avail themselves to any useful purpose of the shipping statistics of Government.

Another difficulty which greatly obstructs the collecting of statistics on the sea performances of mercantile shipping, is the great number of vessels bearing the same name. In many cases, there are scores of vessels bearing the same name, thus rendering it extremely difficult to trace and scrutinize the performance of a vessel of any name with certainty as to her identity; for, in publishing the arrivals and departures of shipping in mercantile navy records, the registered number of a ship, which constitutes the only means of identification, is not generally given in connection with her name.

A further instance of the insufficiency of our present system of shipping registration as statistical data indicative of the size of the hull of steam shipping, is afforded by the statement given in the Appendix, which has been deduced from a return of the House of Commons, showing the per centage deduction from the gross tonnage allowed for the engine rooms of steam-ships, whence we see that, without any reference whatever being made to the actual weight of the machinery, deductions are made from the gross tonnage varying from 5 per cent. to 92 per cent. of the gross measurement, the remainder only being brought to account as the registered tonnage of the ship.

In conclusion, this committee begs to observe, that if the views thus brought before the notice of the British Association should be deemed worthy of further prosecution, and be favourably entertained by the Government, the statistics of the Post-office, as respects the constructive elements, and test trials, and subsequent sea performances of the various steam-ships employed in H. M. Mail Service, would afford a collection of statistical data which, if duly analysed and applied as herein suggested, would greatly promote the objects of this inquiry which the British Association has thus been pleased to institute.

The committee has the painful duty of announcing the death of one of its members, James Perry, Esq.; whose personal character, practical intelligence, and public usefulness, were of such an order, that his decease may be mourned as a public loss.—(Signed)

WILLIAM FAIRBAIRN, Chairman.
CHARLES ATHERTON.
ANDREW HENDERSON.
HENRY WRIGHT.

LIEBIG ON SEWAGE.—The illustrious Liebig has lately addressed the following impressive letter to an English gentleman:—

My Dear Sir,—Pray accept my best thanks for your continued interest in my lectures on theoretical and practical agriculture; they are being translated by Dr. Blyth, of Cork, who has by this time nearly completed them. Since last week I have been lecturing on sewage; and I am firmly of opinion that if England wishes to remain an agricultural country she must use as manure the nightsoil and similar residues produced in large cities. This necessity would be increased in the event of a war with America, when the supplies of guano would cease. The price of corn depends upon that of guano, and it is most unnatural that, in a country like England, the production of corn and meat should be so dependent on the supplies of foreign manure. The heads of even the most enlightened agriculturists have been turned by a theory propounded by Mr. Lawes,—viz., that nitrogen or ammonia are the most necessary ingredients in manure, and that consequently solid excrements are valueless, the urine alone being of use. These views expose utter ignorance, and prove that in England leading agriculturists do not pay sufficient attention to the fundamental principles of chemistry. It is difficult, nay, perhaps impossible, at this moment, to convince them of their error. I have tried to do so in my "Letters on Chemistry" I have just published, and I shall feel most grateful to you, as well as to all who, like yourself, take an interest in the welfare of their country, for any assistance that may be tendered me in propagating this great truth.—Yours, JUSTUS VON LIEBIG.

LITERATURE.

The Construction of Wrought-Iron Bridges, embracing the practical application of the Principles of Mechanics to Wrought-Iron Girder Work. By JOHN HERBERT LATHAM, M.A., Civil Engineer, Fellow of Clare College, Cambridge. *With Numerous Detail Plates.* Cambridge: Macmillan and Co., and 23 Henrietta-street, Covent Garden, London. 1858.

MR. LATHAM, the author of this work, has had advantages which hitherto have not often been possessed by the same individual, for to his mathematical training at Cambridge has been added some valuable practical experience under the late distinguished engineer, Mr. J. M. Rendel. It affords us great satisfaction to see such a work issued from the press, for engineering practice has far outstripped the theoretical knowledge which exists upon the subject, and it is high time that the profession set about properly combining the two. It is undeniable that very few of our eminent engineers have possessed, or even now possess, any considerable knowledge of abstract science. For this they have had to depend almost exclusively upon others, and it has unfortunately happened that their dependence has sometimes been placed in men who have not themselves been either sound or skilled mathematicians. It is most desirable, manifestly, that this state of things should be brought to an end as soon as possible. We want to see the pure but unproductive virgin, *theory*, wedded to lusty *practice*, that from their union may spring a race of useful and comely works, such as we now look for in vain. We would cast no slur upon the engineers of either the past or present. Their want of theory to guide them has been no fault of their own, and without it they have filled the world with marvels. Common men, without position, without education, springing from the workshop, the colliery, the mine, have with their own unaided brains and hands devised and wrought out works which make the miracles of the past ridiculous, and throw the gods of the ancients eternally into shade. All honour to such men! Still, we must systematize the knowledge we have been accumulating by experience; we must bring it into order in the light of true theory. In the writings of Willis, Hodgkinson, Tredgold, and others, we have welcomed every attempt at this, and we now greet Mr. Latham in the same field with a cordial welcome. If he is a young man, as he seems to be, there is a splendid path open for him. He endeavours to narrow the chasm between the literature of our "highest experience" and our "highest reasoning;" and he temperately urges the propriety of shaping the theoretical studies of our universities to a certain extent by what is going on in the practical world. May he gain some success in these respects! In this matter, at least, there need be no "bridal dawn of thunder peals" at the wedding of *thought* with *fact*. The necessary progress may be made gradually, peacefully, and with the happiest results. Only readers who have mastered a moderate amount of mathematics will be able to read the whole of Mr. Latham's work, but it will amply repay the perusal of those who can read it. We have not space to review it here; our readers must content themselves with our assurance that it contains invaluable investigations and information respecting bridges and bridge-work, and that no cultivated engineer should attempt to do without it. The price (15s.) will appear to some rather high, perhaps; but those who know the expense of getting up mathematical matter and engraved plates, and who are able to estimate the intrinsic worth of the volume, will be far from grudging it.

The Literary and Educational Year Book for 1859. London: Kent and Co., Paternoster Row, and Fleet Street.

WE have already expressed a high opinion of this work, but we cannot allow its appearance (after an unexpected delay) to pass without again giving it a good word. It consists of more than 200 pages of tightly-packed information of very various character, and it is difficult to conceive

Digitized by Google

of a person by whom it would not be found of great use. To many it will be invaluable. We are very glad to find that the editor has had the good sense to give scientific persons and scientific matters their just position—which is a very prominent one; and we hope that an extensive sale among scientific individuals and institutions will prove to him that his wisdom in that respect is properly appreciated.

Electricity and the Electric Telegraph; together with the Chemistry of the Stars; an argument touching the Stars and their Inhabitants. By GEORGE WILSON, M.D., F.R.S.E., Regius Professor of Technology, University of Edinburgh, and Director of the Industrial Museum of Scotland. *New Edition, revised,* with the addition of a Description of the Atlantic Cable. London: Longman, Brown, Green, Longmans, and Roberts. 1858.

PROFESSOR G. W. WILSON in this little volume furnishes us with two very eloquent discourses, and besides these a poem. To eloquence he happily adds scientific soundness—which few eloquent men do. His discourse on electricity and the electric telegraph is a very excellent resumé of the principal known facts and theories bearing upon them. His discourse on the chemistry of the stars goes to show that we have no ground for supposing that anything like terrestrial life exists in what are called the "fixed" orbs of heaven. This essay is a very singular and interesting production, and as its first appearance preceded the celebrated "Plurality of Worlds," it should be consulted by those who studied the discussion which followed the issue of that work. The poem is on the Atlantic Cable, and appeared originally in "*Blackwood.*" Now, as then, we read it with astonishment, both on account of its merits and its defects. It seems incredible that the author who wrote

> "So now, methinks, this Earth of ours
> More like to Heaven should be,
> When we have seen an end of Time,
> And there is no more Sea,"

should also have written

> "Then rose the Demon of the Storm,
> And lashed the Vassal-sea,
> Until with desperate hands the link
> He broke in his great agony."

Why, in the name of all the Muses, was the word "great" forced into that last line, which would have been so incomparably superior without it? As specimens of the higher style of Professor Wilson's prose we quote the following passage from the first discourse:—

"In the year 1517, as the historians of the Reformation tells us, the Elector, Frederick of Saxony, had a strange dream. The monk Luther appeared to him, writing upon the door of the palace-chapel at Wittemberg, in his dominions. The pen which Luther handled was so long that its feather-end reached to Rome, and shook the Pope's triple crown on his head. The cardinals and princes of the empire ran up hastily to support the tiara, and one after another tried in vain to break the pen. It crackled, however, as if it had been made of iron, and would not break; and whilst they were wondering at its strength, a loud cry arose, 'and from the monk's long pen issued a host of other pens.' The Elector's dream has been fulfilled in our own day. The long pen of iron sprouting forth hosts of pens is in our hands, and every day grows longer. It *has* reached to Rome, and much further; it has shaken popes' and kings' and emperors' crown; and foretold, like the pen which Belshazzar saw, the fall of thrones and the ruin of dynasties. It has written much of wars and revolutions, and garments rolled in blood, and must write much more. But it is the emblem and minister of peace, and the long pen shall yet vanquish the long sword."

In his second discourse, the author takes the opinions of a lamp-lighter, a stoker, a sailor, a soldier, a poet, and other disinterested parties, upon the starry universe. Let us hear one of them express his views. We will take the sailor, who finishes thus:—

"If there are all these differences among our sailing vessels, are there likely to be fewer among the ships of heaven? Do you think it probable that if by means of some loudest speaking-trumpet we could hail each shining orb with 'Star-a-hoy!' and thereafter, by means of some farthest echoing, reverberating hearing-horn, could get back an answer, that from every one would be returned the same doleful or trivial earthly murmur—*Californian Diggings; Kaffre War; Ministers Outvoted; Fête at Paris; Insurrection in China; His Holiness the Pope's last Bull.* My friends, think of this. In the azure sea above us, there are no shores or landing-places; it is one boundless PACIFIC OCEAN, where the frailest bark never hides behind a bulwark, or drops anchor in a storm. The fleets of heaven are all phantom ships, for ever sailing, but never nearing port. If they are all, then, as nearly as possible identical, why are there so many? If the nature and object of each is the same, why are they not pieced together so as to make up one huge vessel? They might as well have been nailed and hammered into a single mighty sun, or sun-earth, lighting up and darkening itself, while it floated through space, like a gigantic Noah's ark, laden with every living creature."

Who Invented the Locomotive Engine? with a Review of Smiles's "Life of Stephenson." By OSWALD DODD HEDLEY. "*Palmam qui Meruit Ferat.*" London: Ward and Lock, 158 Fleet-street. 1858.

VERY few know how to write the lives of great men wisely. Biographers, with but few exceptions, first make the mistake of overlooking the elements which constitute the true greatness of their heroes, and then commit the further error of supplying what they consider becoming in a great man. The veritable greatness which God gives to the man has substituted for it the best artificial excellencies which the poor author can invent for him. Hence, we are often painfully reminded that His ways are not man's ways, nor His thoughts man's thoughts. We should be very sorry indeed to imply that Mr. Smiles's much-discussed "Life of George Stephenson" is any other than a very excellent work; but, while we give it that credit, we cannot believe that his conception of his hero is precisely a true one. We do not think the illustrious engineer was a less noble or less able man than Mr. Smiles represents; but we do think that gentleman has, to a certain extent, covered ground belonging to others with his monument. This belief is suggested not by the appearance of the volume now before us only, but by several things that have transpired lately, and by others that we knew before. Mr. Oswald Dodd Hedley is decidedly of our opinion in this matter; and, for aught we yet know, of much more than our opinion; for he believes that, in his pages, evidence is adduced "that most irrefragably proves Mr. William Hedley to have been the inventor of the locomotive engine on the present principle." The author (a son of William Hedley, we presume) writes warmly, but ably nevertheless, and should be read by all who take an interest in the question which he discusses. As the whole subject is likely again to come before our notice, and to claim our consideration on an early occasion, we shall at present content ourselves with having stated the object of Mr. Hedley's book, and brought it to the notice of our readers.

On the Military and Naval uses of very large Shells, and the comparative Powers of Shells in relation to Diameter. A Paper read at the United Service Institution, London, May, 1858. By ROBERT MALLET, Memb. Inst., C.E., F.R.S., Hon. Memb. U. S. Inst. From the *Journal of the United Service Institution*, vol. ii. 1858.

IN this paper, which Mr. Mallet has wisely reprinted, we find, 1, on elaborate investigation of the general relations as to power of shells in proportion to calibre, and the proportionate power of 3-foot shells as compared with 13-ins., which are the largest at present in common use in European armies; 2, a description of the construction and form of the celebrated 36-ins. mortars, with which the author, under the personal sanction of the Prince Consort and Lord Palmerston, startled us all a year or two since; 3, a statement of some of the peculiar purposes to which these very large shells are specially applicable. Mr. Mallet is not only a cultivated and sagacious engineer, but is also possessed of such experience in military matters as was to be acquired by presence at the siege of the citadel of Antwerp by the French in 1832. His paper is most valuable. At the very outset of it; he corrects a popular misconception respecting the objects of his large shells, and explains that they are for use, not against troops in the field, but against works—are "the means, in fact, of transferring to any point within range of the besieger an ignited mine, whose penetrative power shall bury it to the required depth before its explosion." After setting forth, first the purposes, and then the construction of his huge mortars, he gives a very excellent review of the history of shells, in which he evinces great research, and then explains in detail what he conceives to be the advantages which would result from the application of his great-shell system to siege operations. The entire paper is of a most entertaining character, and we almost regret that it is not less lengthy, and less remote, as a whole, from our objects; were it so, we should gladly give it *in extenso*. We commend it to the attention of our readers, many of whom have, we know, both naval and military tastes.

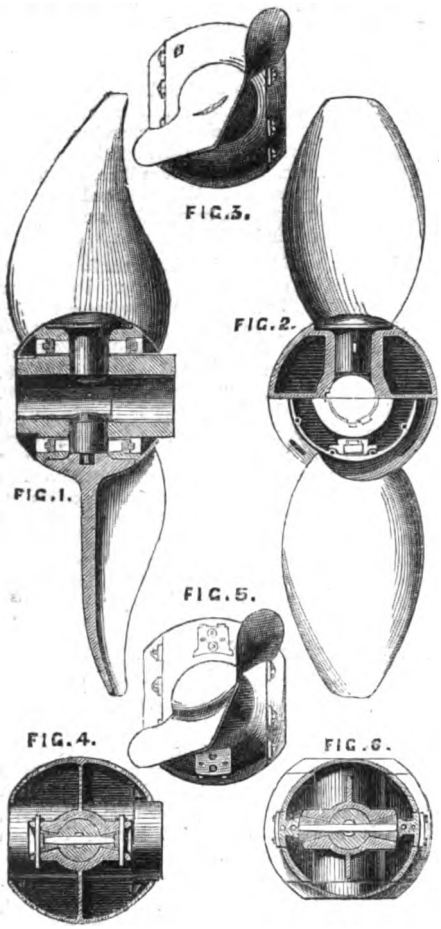
A Discourse on the Study of Science in its Relations to Individuals and to Society. By HENRY HENNESSY, F.R.S., M.R.I.A., Professor of Natural Philosophy in the Catholic University of Ireland. *Second Edition.* Dublin: W. B. Kelly, 8, Grafton Street. London: Simpkin, Marshall, and Co., Stationers' Hall Court. 1859.

THIS is an exceedingly healthy and invigorating discourse, and does great honour, in many ways, to the author. He is evidently imbued, not only with a noble appreciation of science, but also with a consciousness of the harmony which exists between the faculties to which *truth* appeals and those by which *beauty* is embraced. It is from first to last a very manly and generous production. We cannot, of course, attempt to reconcile his liberal language with his religious profession as a Roman catholic; but we care but little for this, especially as his only appeal to his fellow-catholics is designed to stimulate them to intellectual pursuits. We entirely sympathize with his belief that catholics have a right to cultivate science if they please, in halls of their own. Let them do so by all means. The study of science will never make them worse citizens, or greater fanatics; nor will it in any way tend to strengthen that unnatural arrogation of political power by a priesthood, which is now the one great barrier between catholics and protestants.

Description of Griffith's Patent Screw Propeller: with its Recent Improvements. London: Soul, Leadenhall-street, 1858.

WHEN he first introduced his propeller, Mr. Griffiths expected, he here tells us, that considerable advantages would result from an arrangement in its construction, whereby the "pitch," or angle of the blades, could be increased or diminished, and even "feathered," during the voyage with facility, to suit the varying exigencies of sea-going steam-vessels. Experience, however, obtained from many experiments and careful observation, has convinced him, he says, that the risk of derangement, incident to the machinery requisite for this purpose, is too great to admit of practical success, and also that the advantages to be obtained thereby are far less than was supposed; and having lately patented some further improvements in his screw propeller (which is now very generally known), whereby greater speed is obtained, and also greater stability in its construction, with increased facilities for altering the pitch or replacing a broken blade in case of accident without the necessity of docking the vessel, he now draws attention to it by means of this pamphlet. From the engravings, figs. 1 to 6, (next page,) these improvements can be seen. From experiments lately made, he finds that the extremities of the blades do not propel, but act as feeders for the supply of water to the central part of the screw. By curving the blades, as shown on the engraving, from the front or propelling side towards the vessel, the screw (according to Mr. Griffiths) is enabled to get a greater hold of the water, and offer much greater resistance to the power of the engine, in consequence of the water that is drawn from outside the disc in front coming against the propelling side of the blades, instead of their backs, as with straight blades. "The improvements in the construction of my screws," says Mr. Griffiths, "consist in the mode of fixing the blades in their places, and were adopted in consequence of one or two accidents which arose from the giving way of the cast-iron lugs by which the blades were previously fixed. I now substitute for these cast-iron lugs a strong wrought-iron cotter, which

Digitized by Google



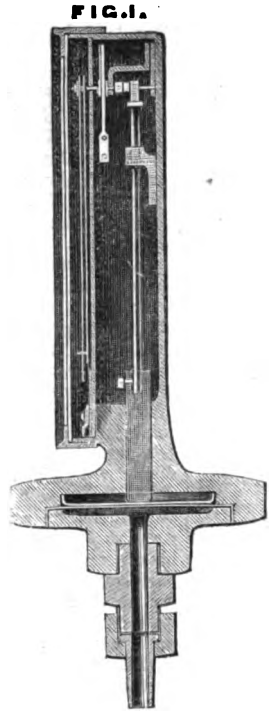
passes through the centre of the shank of the blades, and will entirely do away with any *possibility* of accident from this source. I also considerably increased the diameter of the shanks, and now fit them in such a way that the pitch of the screw can be altered, or a blade removed with much greater facility than before." Amongst the numerous advantages which Mr. Griffiths considers his propeller to possess over all others are, increased speed of vessel, relative to the power employed; less vibration of the vessel; improved facilities for ascertaining the "best pitch" to suit vessels and engines to which it is fitted; the disuse of a spare *screw*, spare *blades* only, which stow in very little room, being necessary; the absence of all necessity for raising or feathering the screw; and the non-liability of the principal propelling portion of the blade, which is near the water, to be lifted out of the water when the vessel is pitching. Mr. Griffiths' pamphlet is well worthy of perusal.

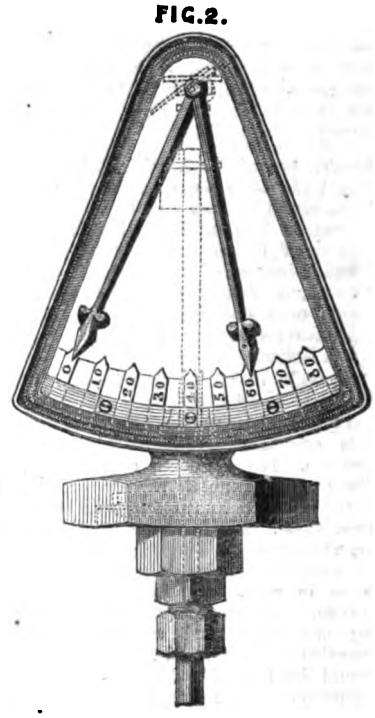
CAPTAIN RAYMOND'S LIFE RAFTS.

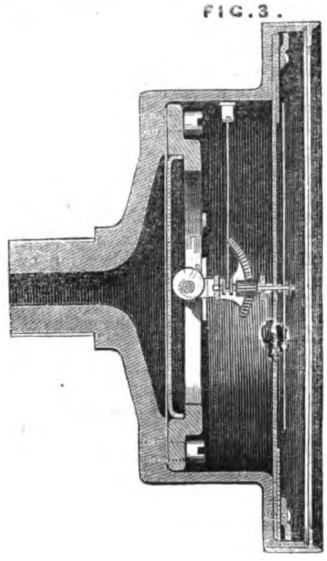
CAPTAIN RAYMOND, of Dalston, last year obtained provisional protection for certain improvements in life rafts, which, we regret to observe, he did not proceed with. He proposed to form his raft of two double galvanised iron cases, cylindrical at top, and flat at bottom. The inner case was to be corrugated, with round ends, and partitioned within; the concave portion filled in with cork, attached by marine glue; then a casing of cork over that, fitting tightly inside the outer case of galvanised sheet iron. To obtain extreme lightness combined with strength, the outer case was to be surrounded at intervals with hollow bands, filled in with cork, to act as fenders, and to contain swivel rings, with the view to prevent numerous lashings in the construction of the life raft. The ends were, also, to be fortified and strengthened by similar means. A space was to be left between the two cases, and the lining of cork even with the openings, fitted with a suitable cover, bag, and plug, to contain rockets, blue lights, lucifer matches, powder, short musketoon, chopper, &c. To the outer were to be fitted iron bars, so arranged that they could be immediately attached to corresponding swivel eyes, thus forming twin tubes with the corresponding bars and marks. When these bars were thrown across and connected, a deck was to be formed on them by means of bamboos or rods of buoyant material. A raft of this description would be speedily constructed, and combine safety, lightness, strength, and durability.

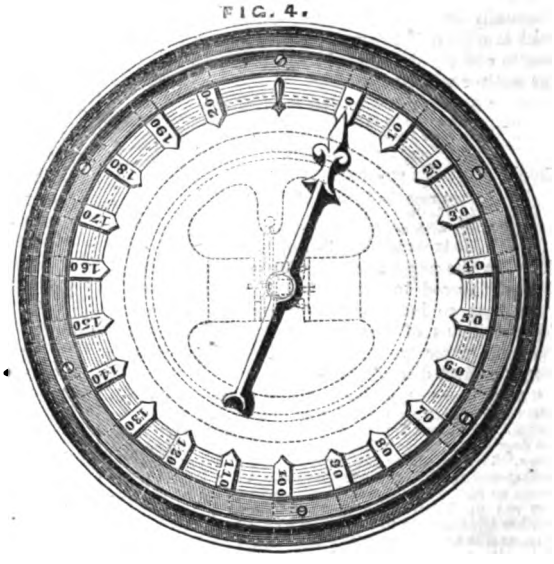
JOHNSON AND VARLEY'S IMPROVED PRESSURE AND VACUUM GAUGES.

Mr. S. W. Johnson and Mr. J. Varley, of Perborough, have submitted to our notice an improved form of pressure gauge, which possesses some important advantages. In the first place, they adopt a new form and arrangement of spring pressure disc or plate, which communicates motion through rods, levers, &c., to the pointer used for indicating the pressure or vacuum. They take a circular plate or disc, and bend up the edge all round till it forms a right angle, or nearly so, with the flat part or body of the disc. They then fit this dished or flanged plate truly into a recess without any other description of fastening, when it is to indicate pressure, with the flanged edge upwards, and in the reverse position when it is to indicate a vacuum. When pressure is exerted on the bottom or back of the disc, the plate springs, or is deflected, and moves about the edge of the flange. In the next place they employ moveable figures on a dial plate, so that the gauge can









be adjusted or changed without disturbing the dial plate itself. Even a new pressure disc may be applied, and the figures be adjusted to it, without any alteration of the dial plate being required.

The annexed engravings illustrate the improvements of Messrs. Johnson and Varley. Fig. 1 is a cross section, and fig. 2 a front elevation of one of their low pressure gauges; fig. 3 is a cross section, and fig. 4 a front elevation of one of their high pressure gauges. The figures are so clearly cut, and the action of such gauges is so well understood by engineers, that we have not thought it necessary to indicate the respective parts by letters of reference. In addition to the advantages mentioned above, it is evident that the form of spring disc adopted in them, being in no way fastened or bound at the edge, will move with great freedom; at the same time a stronger plate than usual can be applied, and greater deflection be given out with safety. In the low pressure gauge an additional pointer is employed for showing the maximum pressure attained. The improved gauges work with great precision and certainty of action, and will, we doubt not, prove very durable.

H. EDWARDS' IMPROVED PIPE-STEM OR TUBE FOR SMOKING.—Mr. Henry Edwards, among other useful patented inventions, has devised a new and improved pipe-stem or tube for smoking, which is adapted for any bowl—meerschaum, china, clay, &c.—prevents the essential oil of the tobacco being drawn into the mouth, and is easily cleaned. This patent Cornucopian pipe, after the insertion in the tube of a small piece of wool, with a few drops of scented water, acts on the principle of the Hookah, and forms what smokers would doubtless consider a luxurious fire-side pipe, imparting fragrance, and destroying the unpleasantness of the tobacco to others. We much approve of the pipe, and as we understand it will be inexpensive, it will, we think, become a favourite with smokers.

NEW ELECTRIC CONDUCTOR.—The power of straw as a conductor of electricty has been utilized in the south of France, no less than eighteen Communes in the neighbourhood of Tarbes having been provided with conductors composed of straw. Experiments show that an electrical shock sufficiently powerful to kill an ox may be discharged by a single straw.—*Athenæum.*

THE CONSERVATION OF FORCE.

(Continued from p. 27)

METAPHYSICS and mental philosophy enter largely into Mr. Grove's disquisitions on natural science. I would not voluntarily enter on a discussion of metaphysical theories, in which the inquirer is like an unfortunate squirrel in a whirling cage, leaping with dizzy speed from bar to bar, but making no progress on his journey. I have been inducted into this doubtful region by my author, and must call for the aid of common sense to help me out again. He will admit nothing into his list of external realities beyond matter and motion. All else is mere mental abstraction. Matter and motion are the only objective facts; all else is subjective fancy. He apologises for using the terms "particles" and "molecules," saying, that they are only employed as the geometer makes use of the terms "lines" or "points," and "in an abstract sense; though there does not exist in fact a thing which has length and breadth without thickness, and though a thing without parts or dimensions is nothing." This statement I should think is narrower than Mr. Grove intended, for it excludes everything except solid space, and perhaps matter. For if he cannot admit an area to be a reality, he will equally object to distance, which has neither breadth nor depth. And if he excludes distance, how can we accept motion, of which distance is a constituent idea? How, too, can depth have the marvellous power of turning nothing into something. If length, breadth, and depth be each equal to nothing, how can the three taken together make up a compound something. Then, again, since we cannot say of a portion of time it is ten feet long, five feet broad, and two feet deep, therefore time itself is "*nothing*." Mind and thought no one will imagine of three linear dimensions, so mind and thought are "*nothing*." Hence follows the outrageous *reductio ad absurdum* (as logicians say): *everything is nothing*. I do not wish to go any further in that direction, so I will turn to the statement of Mr. Grove's views with regard to heat. To this subject, however, the above remarks have a direct relation. Mr. Grove desires his reader to "divest his mind of the impression that heat is anything substantive," and to "put aside the sensation which heat produces in our own bodies," and to judge of the phenomena by the eye only. And what we thus learn, he tells us, amounts to this, "that matter has pertaining to it a molecular repulsive power, a power of dilatation which is communicable by contiguity or proximity." Now, I do not think it philosophical to put aside the sensation which heat produces in our own bodies, when the subject of heat is under investigation. By sensation alone can we examine the external world, and to ignore the sensation of heat if it can teach us anything, is eminently blameworthy. "Heat, thus viewed, is motion, and this molecular motion we may readily change into the motion of masses, or motion in the most ordinary and palpable form; for example, in the steam engine, the piston and all its concomitant masses of matter are moved by the molecular dilatation of the vapour of water."

The same confusion of terms may be observed in these quotations as I alluded to last week; heat is in the same breath stated to be repulsive power and to be motion. Beyond this peculiarity, Mr. Grove's account of the various phenomena associated with the idea of heat does not differ essentially from that ordinarily adopted. He takes great pains to show that the doctrine of what is commonly called *heat* may be intelligibly stated without the use of that term, and without the hypothesis of any substantive cause for the effects which we generally ascribe to heat. But he does not succeed very well, for he seems unable to get through a sentence without introducing the term heat, or some exact equivalent, such as "repellent force," or "repellent power." But if success were attained, as I believe it might be, no good could result from the achievement. The analytic mind, on witnessing the phenomena, would naturally conceive the idea of heat, and would demand for this idea a distinct verbal symbol. What matter whether the name adopted be *heat*, *caloric*, repellent force, expansiveness? The last would perhaps come nearest to Mr. Grove's ideal of a scientific term. But there is this objection to it, that heat manifests itself not always as an expansive, but sometimes also as a contractive agent—an objection which Mr. Grove endeavours to answer and remove; but I think his effort ineffectual. On this account the term heat is preferable to those in favour with Mr. Grove, as it does not imply uniformity of manifestation, while it connects the phenomena in question with one of our most common and constant sensations.

It may be readily shown that the law of the equality and opposition of action and re-action holds in all the ordinary phenomena of heat. When two bodies of different temperatures are put in communication, in no very long time the temperature of one will be diminished, and that of the other increased, till both assume exactly the same condition. Now in this interchange of actions it is proved by a variety of calculations and of experiments that the heat abstracted from the warmer body is exacly equal to that acquired by the colder. You cannot indeed make the body which has received restore the heat to the giver, and so prove the doctrine by causing the two bodies to return to their original state without a fresh supply of heat, or its equivalent. But it may be shown by using an independent source of heat, that the same action as will restore to the one body the heat which it has lost, would have been exactly sufficient to produce the change which has taken place in the other. This I believe is the correct statement of the principal property of heat, and it is, perhaps, a complete expression of the law of action and reaction in all natural phenomena, in which heat alone is concerned. But Mr. Grove's statement of the conservative properties of this agent is of a very different character; and therefore is, in my opinion, open to serious objection. A good deal which he advances I do not understand, and therefore shall not attempt to criticise, but there are a few statements and modes of argument for the rejection of which I believe I can show sufficient reason. Take the following extract:—

"Assuming that (with the exception of bodies which expand in freezing, where through a limited range of temperature the converse effects obtain) whenever a body is compressed it is heated—*i.e.*, it expands neighbouring substances; whenever it is dilated or increased in volume it is cooled—*i.e.*, it contracts neighbouring substances, the conclusion appears to me inevitable that the mechanical power produced by heat will be definite, or the same for a given amount or intensity of heat, whatever be the substance acted on."

I should not be able, for my own part, to perceive the necessary connection of this grand conclusion with the facts cited, even if the important exceptions given in the parenthesis did not exist. Still less, then, are my faculties equal to the leap which separates the above premises from the conclusion when these wide barriers come between. Here follows, however, a proof which is intended to bridge the chasm:—

"Thus let *A* be a definite source of heat, say a pound of mercury at a temperature of 400°; let *B* be another and similar source of heat. Suppose *A* to be employed to raise a piston by the dilatation of air, and *B* to raise another piston by the dilatation of the vapour of water. Imagine the pistons attached to a beam, so that they oppose each other's action, and thus represent a sort of colorific balance. If *A* being applied to air could conquer *B*, which is applied to water, it would depress or throw back the piston of the latter, and, by compressing the vapour, occasion an increase of temperature; this in its turn would raise the temperature of the source of heat, so that we should have the anomally that a pound of mercury at 400° could heat another pound of mercury at 400° to 401°, or to some point higher than its original temperature, and this without any adventitious aid: it will be obvious that this is impossible, at least contradictory to our whole range of experience."

One seldom meets with so complete a sophism as this. Major proposition is wrong, minor proposition is wrong, conclusion is wrong. The argument stands thus:—

I. One pound of mercury at 400° cannot, without adventitious aid, heat another pound of mercury at 400° to a temperature higher than 400°.

II. If, after the application of the two separate pounds of mercury to the two gases, as described in the above extract, the pressure of one gas preponderated, the temperature of the opposite pound of mercury would be so raised.

III. Therefore the pressure developed in the one fluid must be equal to that developed in the other.

With regard to the first proposition, if we adopt partially Mr. Grove's own method, we may readily prove that a pound of mercury at 400° may raise another pound of mercury at 400° to a higher temperature. We may make the following assumptions without outrage to any known physical law—viz., that the air is itself at a temperature of 400°; that the steam is at a temperature of 800°; that the area of the pistons are equal; that the beam which connects the two pistons is pivoted at its centre; and that the two fluids at first are of equal pressure and volumes. Now apply the two pounds of mercury at 400° one to each of the fluids. To the air, which is already at 400°, no heat will be communicated, and therefore its pressure will not, by this means, be increased. The steam, however, will receive an accession of temperature from the mercury, its pressure will be augmented, and a consequent expansion of the steam and compression of air will take place. Now, this compression of the air will be accompanied by a corresponding increase of its temperature and pressure. And the increased temperature of the air will be communicated to the mercury with which it is in contact. Hence, one pound of mercury at 400° may, without adventitious aid, raise another pound of mercury from 400° to a higher temperature.

The second proposition is of equal merit, for it by no means follows that the preponderance of the pressure of one of the gases would increase the temperature of the other to a point *above* 400°. If the temperatures of the two gases, to begin with, were both less than 400°, they would still be less than 400° when their temperatures were equalised with the mercury. And thus all that could be said if the pressure of either began to preponderate, would be that the temperature of the other gas would be raised above this mean temperature—not necessarily above the 400°. Indeed, it seems to me that however this experiment is imagined to be varied, in every case in which the first proposition is not falsified the second is untrue.

The conclusion itself so far from being a general truth, will not hold for the most simple variations of this single experiment. It is allowable to suppose that the air and the steam are at first of equal temperatures, equal pressures, equal weights, and enclosed in equal cylinders, and acting on pistons of equal area, attached to an equal armed lever. Now, in such a case, if Amonton's law be worth anything, the pressures of these two quantities of gas will continue equal only while their temperatures are equal. And if, as is likely, their specific heats are different, the same amount of caloric added to each will make their temperatures different, and therefore their pressures unequal, and the pressure of one will conquer that of the other. Mr. Grove attaches to his experiments none of the conditions of equality which I have put forward, and I imagine he did not have them in view. If in addition to the inequality of specific heats there are also inequality of area of pistons, initial temperature, weight of gas, or arms of lever, Mr. Grove's syllogism becomes still more distorted. The difficulty would be to find a case in which the proposition would hold, unless the two parts of the experiment were made with the same gas under identical conditions.

A MECHANIC.

MONUMENT TO DR. KANE.—It is proposed to erect a monument to the memory of the late Dr. Kane in the central Park at New York. A course of lectures in aid of the object will be given at the Cooper Institute.

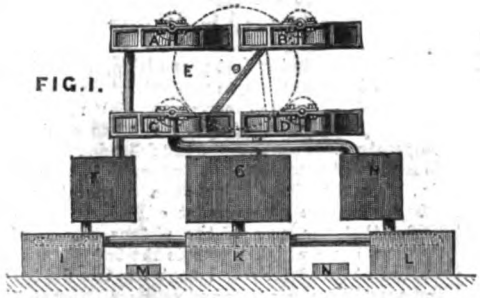
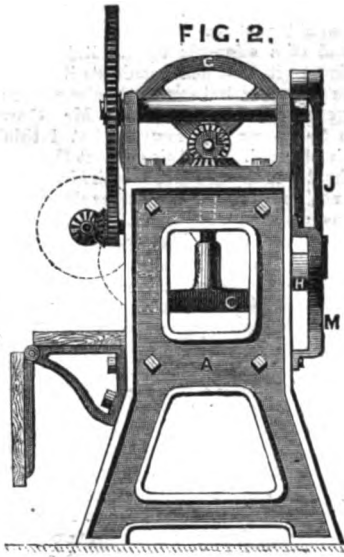
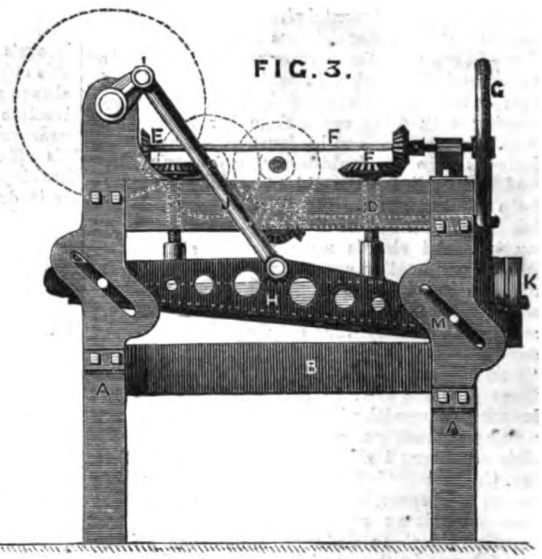
WHITELEY'S APPARATUS FOR MAKING MILLBOARD, ETC.





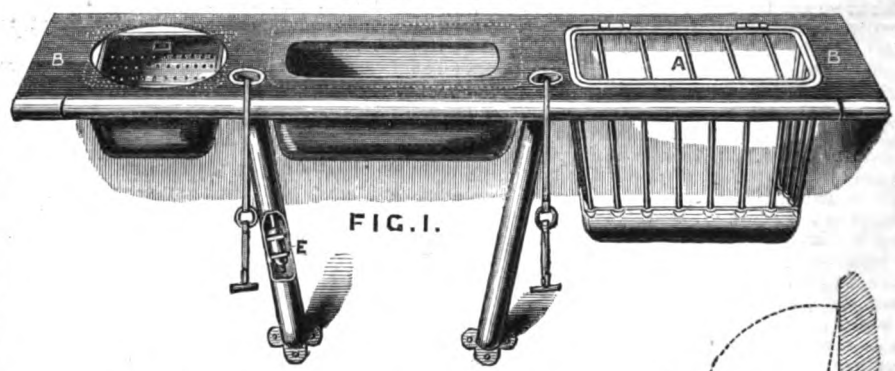


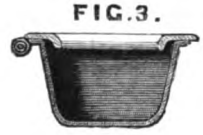
MR. J. WHITELEY, of the firm of J. Whiteley and Son, Firth House Mills, Stainland, near Halifax, have patented the following improvement in apparatus for making millboard and for cutting millboard and paper. These improvements are of a manifestly useful character, and need no recommendation from us. The invention relates, 1, to the manufacture of millboard composed of different qualities and colours of materials, and consists in so arranging and working the machinery or apparatus used for grinding and washing the various pulps simultaneously, and in juxtaposition, that the patentee is enabled to make the middle portion of the millboard of inferior or coarse material, and the outside of a finer quality, and of a different colour, as may be required. Heretofore, paper or pasteboard (resembling millboard) has been made by first forming a millboard middle of coarse or inferior pulps with the outsides of a finer quality and of different colours, but in the process of manufacture each part when formed had to be dried and rolled, and then pasted together; but by these improvements millboards of various qualities and colours can be manufactured at one operation, thereby saving the time required to dry the separate sheets, and also the costs of rolling, pasting, &c. This part of the invention is performed by having several washing and breaking or grinding engines arranged side by side, or in such other relative position that they can be worked simultaneously, in order that one or more of the engines can be operating upon one quality or colour of materials, whilst other engines are operating upon other qualities or colours, the products thereof being conducted to their respective "pulp chests" and "vats," which are placed side by side, or in such relative positions that one workman or more can be making the middle layers of the pulp from coarse materials whilst other workmen are making the outside layers of finer qualities of pulp, or of different colours, as may be required, each man placing his layer of formed pulp in the proper relative position on the same pile to form one millboard, according to the thickness, quality, or variety of colour that may be required. 2, the invention relates to machinery or apparatus employed for cutting off the edge of millboard and paper to form the proper size of sheets, and consists in the application of a straight-edged knife, set or arranged so as to be at an angle with the bed of the machine or press in which the millboard is placed for cutting, and imparting to such knife a slide cut by means of a crank and connecting rod with suitable guides for the knife.

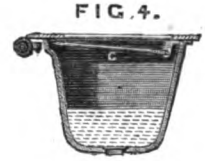
Fig. 1 of the accompanying engravings is an elevation of the apparatus employed for manufacturing millboard, constructed and arranged for carrying out the first part of this invention. *A*, *B*, *C*, *D* are the washing and breaking or grinding engines, which are all driven by spur pinions gearing in with the main driving wheel *E*. The products or pulps are conducted by pipes to the pulp chests *F*, *G*, *H*, from which they are drawn away by other pipes to the vats *I*, *K*, *L*. It will be seen that whilst one, two, or three of the engines are employed in grinding inferior materials for the middles, the other may be employed in grinding a fine quality or coloured material for outsides, the products of each being conducted to separate pulp chests for supplying their respective vats. The conducting pipes from the upper engines are flexible, so that they can be readily changed from one to the other of the lower engines, and the pipes from the engines to the pulp chests and vats are supplied with sluices or stop valves so as to change the course or flow of the pulp to any of the chests or vats as may be required; or flexible pipes may be employed. It will also be readily seen that if a fine qualitity of pulp be conducted to the vat *K*, and an inferior quality to the vats *I*, *L*, the makers at *K* would pass their "dips" to each pile or piller *M*, *N*, whilst the makers at *I* would pass to *M*, and the makers at *K* will pass to *N*, according to the number of dips or layers of each required, by which means the inventor is enabled to make millboard of different qualities or colours of material at one operation.

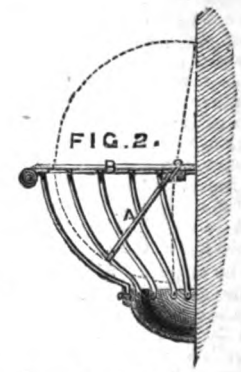
The second part of the invention will be understood by reference to fig. 2, which is an end elevation, and to fig. 3, which is a front elevation of the machine for cutting off the edges of millboard and paper. *A*, *A* are the end frames; *B* is the bed of the machine on which millboards, &c., are laid for cutting; *C* is a presser forced down by the screws *D*, bevil gear *E*, and shaft *F*, with the hand-wheel *G* for holding the materials in position; *H* is a knife set at an angle with the bed, the motion of which is derived through the crank *I* and connecting rod *J*, by the train of spur and bevil gear from the driving pulleys *K*. The knife is caused to slide in an oblique manner by the studs *L*, which are guided by the slot plates *M* affixed to the frame of the machine.

HOOD'S PATENT STABLE FITTINGS.





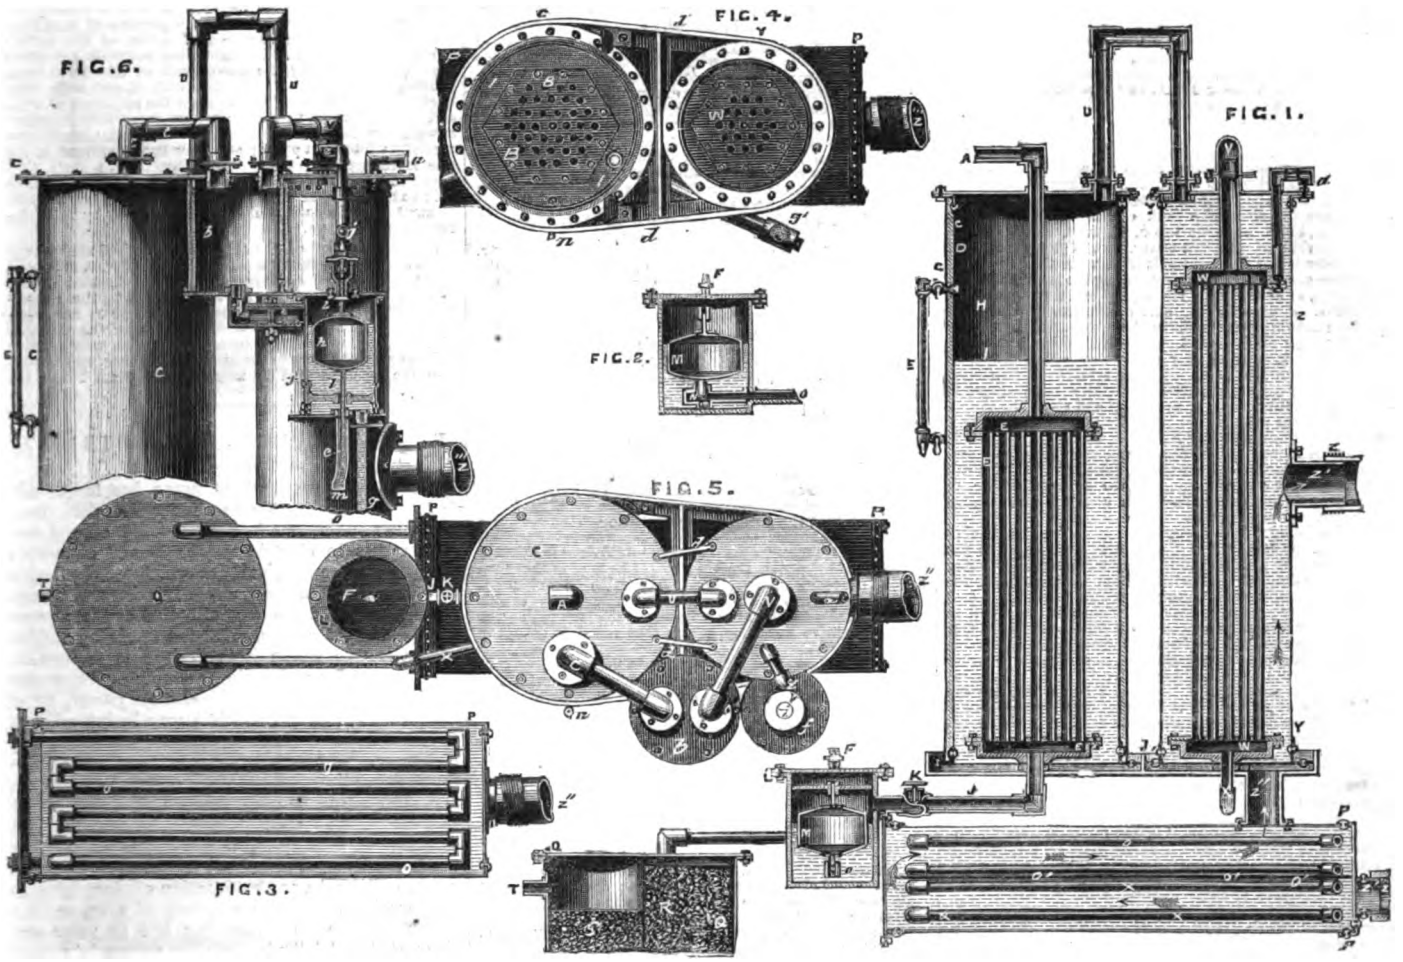




IRON stable-fittings—consisting of a rack and manger, or a rack, manger, and water-cistern, in one range, by which a horse was enabled to feed in his natural position—were introduced about ten years ago. The previous system of feeding from racks over-head was the cause of much irritation and injury to the animal, and of much trouble to the attendant, from the seeds and dust falling on to the head and into the eyes of the animal; and the introduction of the new fittings, with which these evils were not possible, was consequently regarded as a very great improvement. Even these, however, were found imperfect in some respects. In the first place, horses were found to injure themselves by striking themselves against the fittings, many of which had the top-plates merely turned down in front, presenting a sharp edge against which the knees of the horses frequently got cut. This defect is now obviated in the best kind of fittings by the application of a wrought-iron tube or roller extending along the front, which revolves upon being rubbed or struck against by the horse. In the next place, the waste caused by the feeding has always been a serious drawback to the use of the new iron fittings. This and some other disadvantages have

Digitized by Google

NORMANDY'S PATENT MARINE FRESH WATER APPARATUS.



lately, however, been remedied by Mr. Hood, iron-merchant, of Upper Thames-street, London. The woodcuts annexed illustrate Mr. Hood's improvements. It will be seen that the patentee has, by exceedingly simple and inexpensive contrivances, effected the following improvements, viz.:—1st. Waste from the rack is prevented by a grating, *A*, figs. 1 and 2, fixed to the top-plate, *B*, by means of two spring hinges. This grating opens back to the wall whilst the rack is being filled, and then follows the course indicated by dotted lines in fig. 2 as the hay is being withdrawn, always so compressing it that the horse is unable to withdraw it wastefully. 2nd. The top-plate having a flange projecting inwards all round of the form shown in section, fig. 3, renders it impossible for either corn or chaff to be thrown out of the manger. 3rd. The water-cistern is fitted with a cover, *C*, figs. 1 and 4; for although, as a rule, a horse should always be allowed to drink when he requires, still there are times when —on entering the stable in a state of heat, for example—the privilege should be withdrawn temporarily. In this instance the cover, *C*, consists of perforated metal (the edges being covered with gutta percha or similar substance, to prevent noise and the chipping of the enamel with which the cistern is lined), working in slots so constructed that the horse cannot interfere with its action. 4th. The tubes, *D*, in which the tying apparatus works, act as brackets for the support of the fittings, and also prevent the balls from getting under the horse's feet. The tying apparatus itself is rendered noiseless by the balls, *E*, which work inside of the tubes, being covered with a non-resonant substance. These improvements are manifestly the result of practical experience, and as they will promote economy, security, and comfort, we strongly recommend them.

NORMANDY'S PATENT MARINE FRESH WATER APPARATUS.

A SERIES of experiments has recently been made by direction of the Board of Admiralty, with a view to ascertain by what apparatus the largest and best supply of water can be obtained for the use of ships at sea. The experiments have been made upon the apparatus invented by Mr. (now Sir R.) Grant, and that invented by Dr. Normandy, the well-known chemist, of London. The first was made on Saturday week, on board the *Sphinx*, in the steam-basin, Portsmouth, under the superintendence of Captain G. T. Gordon, C.B., of the *Hannibal*, and Captain Harris, of the *Illustrious*, assisted by Mr. Murdock, inspector of machinery afloat. The quantity of water produced by Dr. Normandy's apparatus is said to have been 92 gallons, with a specified quantity of coals. With the same quantity of fuel, under the same conditions, and with the same boiler, Sir R. Grant's apparatus (under the superintendence of Mr. Miller, of the condensing department) was tested on board the *Erebus*, on Friday last, and the result is said to have been the production of only 32 gallons of water. There is also this important difference in the qualities of the water produced —that Sir R. Grant's is purely distilled water, whereas the other becomes aërated in the process of distillation, and is perfectly cold and fit for use when it leaves the apparatus.

With these experiments before us, we have thought it desirable to publish a description of the improved apparatus, that its nature and advantages may be thoroughly understood and generally known. It should be further stated, that the trials above mentioned are by no means the first that have been made with Dr. Normandy's machines, for they were fitted, to the number of twelve, on the island of Heligoland, while the Foreign Legion was stationed there during the war, giving great satisfaction to the governor, and others have since been purchased by the Peninsular and Oriental Steam Packet Company, the Royal Mail Steam Packet Company, the Prussian Government, &c., &c.

The accompanying engravings represent the apparatus in its most improved form:—

Fig. 1 is a vertical section of the apparatus; fig. 2, a vertical transverse section of the steam trap L; fig. 3 is a horizontal section of the refrigerator *P*; fig. 4 is a horizontal section of the cylinder *C* and condenser *Y*; fig. 5 is a plan of the apparatus; fig. 6 is an elevation of the upper part of the apparatus, showing a vertical section of the priming box and of the feed box. *Description of Figure* 1.—*A*, steam pipe from a boiler leading the steam thereof into the vertical tubes *B*. *B*, evaporating tubes placed in a cylinder, called the evaporator. *C*, cylinder, called the evaporator, containing the tubes and the sea water to be evaporated, and which for this reason is called the evaporator. *D*, felt surrounding the cylinder *C*, in order to prevent loss of heat by radiation. *E*, water gauge. *F*, air cock of the steam trap *L*. *G*, outer casing. *H*, steam room. *I*, sea water to be evaporated. *J*, pipe leading the condensed steam into the steam trap *L*. *K*, intermediate cock between the steam trap and the evaporator, which cock is always left open, and is used only in case the float should become water-logged. *L*, steam trap—it is a cast-iron box containing a float. *M*, provided with a plunger, *N*, acting in such a way that when the cast-iron box *L* contains only steam or a quantity of condensed water insufficient to buoy the float, the plunger closes the exit pipe *O*, but as soon as enough condensed steam has accumulated to buoy up the float, the plunger of course no longer closes the exit pipe *O*, and the condensed water may then escape as fast as it is produced. *M*, float just alluded to in the steam trap *L*. *N*, plunger of float *M* just alluded to. *O*, exit pipe for the condensed steam, which pipe is coiled in two layers in the upper portion of the refrigerator *P*, whence it issues in a cooled state to enter the filter *Q*. *P* is a box, or refrigerator, for the purpose of cooling the water which has been condensed by the tubes B of the evaporator, whence it flows into the steam trap *L*, and thence into the tubes *O*; and also for cooling the water condensed by the tubes *W*, of the condenser, whence it flows into the tubes *X*, in the said refrigerator. This refrigerator, as is seen, has a partition *O'*, for separating the two sets of pipes *O* and *X*, and causing the cold sea water to circulate in the direction of the arrows. *Q* is the filter for receiving the condensed

Digitized by Google

water from both pipes, *O*, of the evaporator, and *X*, of the condenser. This filter, as is seen, is divided into two portions, *R*, *S*, each of which is filled with animal charcoal, as represented. *R*, *S*, divisions of the filter. *T* is the pipe for the exit of the perfect fresh water. *U* is the air pipe, leading the air which separates from the water *Z*, used for condensation, into the steam chamber *H* of the evaporator. *V*, pipe admitting the steam from the priming box *b* into the pipes *W* of the condenser *Y*. *X*, exit pipe for the condensed steam, which pipe is subsequently coiled into two layers in the lower portion of the refrigerator *P*, and thence into the filter *Q*. *Y*, condenser, or cylinder, containing the condensing pipes *w*, *w*. *Z*, sea water used for condensation, and which enters the apparatus through the apertures *Z' Z'* and *Z''*, connected with two holes, *Z' Z'*, communicating with the salt water outside, either through the walls of the ship, or through the sides of a tank containing the said salt water. *Z'*, holes, or large tubes, through which the apparatus is charged with salt water. *Z''*, pipe by which the refrigerator is put in communication with the condenser. *Z'''*, tubes of caoutchouc for connecting the tube in the side of the ship, or of the tank containing sea water, with the apparatus. *a*, pipe for the exit of the excess of air, and also for removing pressure from the apparatus.

Descriptions of Figures 3, 4, 5.—*b*, Priming box,—it is simply a box into which any salt water which might be mechanically or otherwise projected, is arrested and carried back again by pipe *e*, into the evaporator *C*, as shown in fig. 6. *c* is a tube carrying the steam and air of the evaporator *C* into the priming box *b*, and thence through pipe *V* into the condensing tubes (*W*, fig. 1) of the condenser *Y*. *d*, *d*, straps of iron uniting the evaporator *C* with the condenser *Y*. *g*, tube by which the evaporator is fed with salt water. *s*, brine cock for removing the saturated water, or preventing saturation by allowing a constant discharge of sea water. *q*, feeding pipe.

Description of Figure 6.—*e*, tube connecting the priming box *b* with the feeding box *f*, and thus returning into the evaporator *C* by means of pipe *g*, any salt water which may be projected into the said priming box. *c*, pipe leading the steam from evaporator *C* into the priming box *b*. *f*, feed box containing a float *h*, provided with a valve *i*, and so adjusted that when the evaporator is filled with the proper quantity of water, the float being buoyed up will close the valve, and thus prevent the flow of any more salt water into it. *i*, valve provided at top with a detached vulcanized India rubber covering. *j*, hand cock for regulating the feed, in case of any accident interfering with the proper working of the float *h*, or of the valve *i*. *l*, guide rod hanging freely into a sheath or tube of vulcanized caoutchouc, so that by grasping it through the tube of caoutchouc, the operator may freely move the float to which it is attached up and down, and thus ascertain whether it is working properly or not. *m*, vulcanized caoutchouc tube.

The manner of working the apparatus is as follows:—

The first thing to be done is of course to charge the apparatus with water, and this is easily done by establishing a communication between *Z'* and the external salt water, whereupon the salt water fills up both the refrigerator *P*, and the condenser *Y*, then passes through the feed tube *q*, through the feed cock *j* (which should be left always open except on an emergency, that is to say, except the valve *i*, or the float *h*, should become damaged or out of order, in which case the supply of salt water to the apparatus would have to be regulated by the cock *j*), thence through the valve *i* into the feed box *f*, down through pipe *g* into the evaporator *C*, up to a line standing at about the middle of the gauge glass *E*, where it is maintained at a uniform level by the float *h*, which is then buoyed up so as to close the valve *i*, whereby all supply of salt water is shut off until such time as by evaporation, or blowing off the brine, the level of the water in *E* will have been lowered, whereupon the float *h* sinking, will allow a fresh quantity of salt water to flow in, and the level will be restored. The valve *i*, as it is seen, is provided at its upper extremity with a stem, rounded at the top, and touching, or nearly so, the caoutchouc covering, so that on pushing the caoutchouc covering with the finger, the operator is enabled at any time to feel that the float is acting properly. The apparatus being charged as just said, and admitting that the pipe *A* is in communication with the boiler charged with steam, it is evident that on turning the steam on it will rush through pipe *A* into the pipes *B* of the evaporator, in which it will be condensed by the salt water which surrounds them, and flow in the state of condensed non-aërated water through the pipes *J* into the steam trap *L*, and thence through the pipes *O* in the refrigerator *P* to the filter *Q*, whence it will issue at *T*. But the heat of the steam in the pipes *B* of the evaporator soon brings the water *I* round them to the boiling point, and converts it into steam; that steam passes through the pipe *c*, *c*, *c*, into the priming or safety box *b*, in which any salt water with which the said steam may be mixed, is deposited and returned through pipe *g* to the evaporator whence it came, while the pure steam continues its course through the pipe *V*, *V*, into the condensing pipes *W*, immersed in the salt water contained in the condenser *Y*, whence it flows, in the state of aërated water, into the pipe *X*, coiled up like pipe *O* in the refrigerator *P*, and thence into the filter *Q*, where it mixes with the non-aërated water of pipe *O*; both the aërated and non-aërated water flowing out together at *T* in the state of pure fresh water, containing an average quantity of air equal to that of river water, and perfectly sparkling, palatable, and fresh.

The aëration is thus effected: the steam coming through the pipe *V* at the top of the condenser, and into the pipes *W*, heats the sea water outside of these pipes in the condenser, between the large hole *Z'* and the top of the condenser, to a degree sufficient to liberate or disengage the air contained in that condensing salt water; the air thus liberated ascends into the air pipe *U*, and is poured into the steam-chamber *H*, where it mixes with the steam contained in that space, and thus the steam which passes through pipes *c*, *c*, *c*, and *V*, *V*, is not steam only, but a mixture of steam and air, so that the result of the condensation is fresh water aërated to the maximum, the superabundant air being discharged through the pipe *a*.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Ordinary Meeting, January 11th, 1859. W. FAIRBAIRN, F.R.S., &c., *President, in the Chair.*

THE President exhibited various specimens of the iron of certain locomotive boilers which had been found to have suffered local corrosion of a dangerous kind, after only a few years' work. The first specimen was from the boiler of the goods locomotive engine "Goliah," built by Messrs. Hick and Son, in 1839. It was a part of the fire-box, through which one of the longitudinal stays had passed. The iron (Low Moor) had been cut away by the corrosive action in grooves radiating from the stay as a centre. The second specimen, taken from the same engine, and likewise of Low Moor iron, was from a part which had been rent asunder in the explosion of the boiler in 1847, before the engine was nine years old. A third specimen was from the boiler of the "Bat" goods locomotive, built by Mr. Woods. It consisted of a part of the angle iron ring at the smoke-box end. A deep groove had been formed by the corrosive action, and water escaped through the angle iron after the engine had worked less than six years. A fourth specimen was taken from the passenger locomotive "Ostrich," built by the Liverpool and Manchester Railway Company. The bottom plate of this boiler, made of Low Moor iron, had been corroded in less than four years to such an extent that water escaped throught it. The President observed that these remarkable effects belonged exclusively to locomotive boilers, and had not been noticed in those of stationary engines. He recommended the subject to the attention of the Society as one of scientific interest, as well as great practical importance, indicating, as it did, a source of hitherto unsuspected danger.

A lengthened conversation ensued, some members being of opinion that the phenomena were owing to the vibratory motion of the engine, predisposing certain parts to chemical action. Others thought that currents might exist in uniform directions, by which the part might be kept in that condition, as to cleanliness, most favourable to oxidation. Several members thought that the action was owing to galvanic currents arising from portions of the iron taking the electro-negative condition, which that metal is so apt to assume.

Professor Roscoe called attention to the pernicious consequences attending the use of unglazed arsenical green paper hangings. His own experience corroborated the observation of Dr. Taylor, that dust collected in rooms, so hung, contained a large quantity of arsenic. He had analyzed the dust from the shelves, &c., of a room occupied by himself, and had found a considerable quantity of this poisonous substance.

Mr. Dyer read a paper on "Imponderable Matter, considered as an *Element*."

He stated, that about two years ago, his first paper on the "Nature of Heat," was read before the Society, and he therein maintained that the "Matter of Heat" was not a misnomer, but, in fact, a material element, that pervaded all space and all bodies in the universe; and in its neutral state was identical with the electrical and magnetic fluids, as also with light, or the luminous principle.

Since then, he had read three other papers, to illustrate and explain his views of elemental heat, and its agency in phenomena, exhibited by its mutations from the elemental state, into and out of the conditions commonly expressed by the terms sensible, radiating, and latent heat; the present paper being intended to give a summary of the views advanced in the former. For the sake of brevity, his own is treated as a "heat-force theory," to denote its being opposed to the "force-heat theory;" and considering that this latter theory has been advocated by many eminent philosophers among the ancients, as well as the moderns, it would be a great temerity in him to oppose that theory, unless he had some strong grounds of objections to offer to it, as well as those in support of his own views. In explanation of these, he said, the common terms applied to heat in its sensible, radiating, and latent states, do not apply to or convey the meaning he attaches to the term "neutral and elemental heat," which condition he defines to be "an imponderable, elastic element" that permeates, and his equally diffused through matter and space, except when its elastic force is exceeded by other disturbing forces. Many instances of such disturbing forces were set forth and explained, and in reference to these he observed, "that great confusion had arisen from the vague and discordant senses in which the term 'physical force' is often employed by very eminent physicists." In treating of the "nature" and "conservation of force," the term is said to mean "that which produces or resists motion," thus implying that force is of itself a substantial existence, whereas it merely indicates action among bodies. These exert force upon one another, and upon their own component parts, so that force means exerted action of matter upon matter, and to give it substantial attributes is absurd.

In support of the identity of heat and electricity, many cases were cited.—(1.) That heat ascends latent in aqueous vapour, which being condensed, the latent heat becomes neutral or elemental in the upper regions, and this *because* no substance is present other than "the thin cold air" with which it can unite and become sensible heat. This neutral element is the electric fluid, and is made known to us in all the forms of electrical phenomena.—(2.) Again, when water descends through the crevices of the earth down to the incandescent mass, it is converted into steam of great force, causing volcanic eruptions and earthquakes, according to the intensities of the forces so generated, by the union of water with heat. This heat latent in the vapour, ascends and is liberated in the upper air, and flashes forth as lightning, always attending those convulsions, and proving the identity of the calorific element with the electrical phenomena so exhibited. It was stated that his (Mr. Dyer's) heat-force theory was in strict accordance with Dr. Black's latent heat doctrine, and that it went to support it, and to explain some anomalous cases that had been adduced against the beautiful system of latent heat so long an established basis of wide ranges of phenomena, alike in nature and in art. Considering that the "force-heat theory" is inconsistent with Dr. Black's, and as this latter is embodied on most of the standard works on physics, it should not be abandoned to make way for another theory that fails to account for such phenomena. Apart from the mutations of heat from chemical changes, the mechanical action of the earth's movements was described as exhibiting magnetic and luminous phenomena, by the movements of elemental heat, proving these also to be identical with it, and with electricity. He then proceeded to show the sameness of light and heat, as proved by the many incontrovertible instances advanced of their inseparable connection, and mutual convertibility into each other; and thus finally arrived at the sole inference fairly to be drawn therefrom, namely, that heat and light, as also heat, electricity, and magnetism, are only so many different conditions in which the one calorific element exists in nature, and manifests itself by its mutations in phenomena.

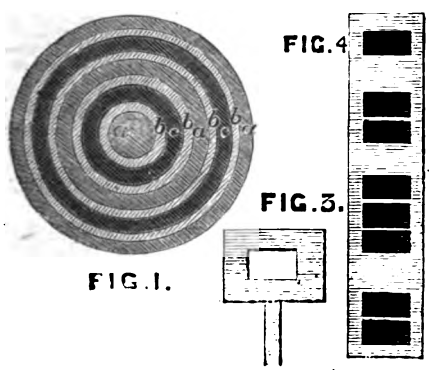
Dr. Joule described the experiments he had made many years ago on the thermal effects of the dilation of elastic fluids, which he considered fatal to the doctrine of the materiality of heat. He called attention to the experiments which Mr. Dyer had made twenty years ago, indicating the possibility of generating heat by the agitation of water. These experiments, he believed, would prove to be of great interest to the history of science, and trusted that the author would be able to place them before the society.

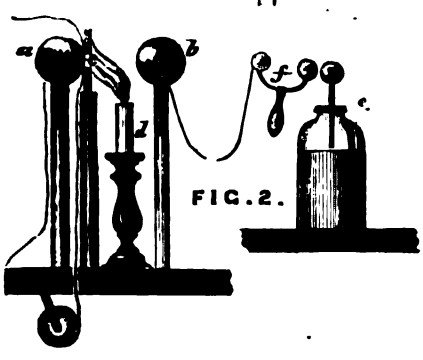
BAGGS' IMPROVED ELECTRICAL APPARATUS.

MR. ISHAM BAGGS, whose name has frequently been before the public in connection with electrical inventions, has lately patented several improvements in electric telegraphs and apparatus employed therewith, parts of which are applicable to other electrical purposes. His invention consists, 1, in the use and application at the remote end or ends of a wire, or at the receiving station or stations to which it is desired to convey intelligence, of an electric reservoir or reservoirs capable of accumulating the electric power, or of rendering the effects which it may be intended to produce more decisive or concentrated in their character. These reservoirs consist of coated surfaces, formed on the principle of the Leyden jar, arranged either as a simple electrical element or as a compound series. Coiled wire may be used in place of coatings, but the principle used in every case is that of induction. By this arrangement, if there be any retardation of electricity in a submarine wire, or in an overland wire, or in a subterranean wire connecting two or more stations, the electricity is caused to accumulate until it reaches the required intensity or force, when discharge takes place at the remote station or stations. 2. Wherever it may be desirable to exalt the intensity of the induced electricity from a coil, he causes such electricity, whether produced from one or more coils, to accumulate in condensers, or their electrical analogues arranged as a series of Leyden jars, whereby electrical manifestations of any required intensity may be produced. Also, if in any such arrangement only the first surface of a series be connected with the positive and the last with the negative, or vice versâ, or if the first be connected with a source of electricity, whether positive or negative, and the last with the ground, it will be found that the intensity is greatly exalted. 3. Where a succession of makes and breaks of contact are required to be made with great velocity or regularity in developing the successive electrical impulses of the coil, he employs machinery, when necessary, for such purposes, embodying proper mechanical contrivances for the regulation of speed and synchronous discharge, such as multiplying wheels, the fly, a wind or water regulator, &c. 4. His invention consists in the use of electricity to deflect flame, gases, vapours, or light bodies through stencilled plates or otherwise, in order to mark or record telegraphic communications upon substances or materials fit to receive them. He remarks that it is not necessary to use points in all cases for such purposes, as quiet discharge and consequent deflection of some of the bodies referred to will take place between conducting knobs, or, indeed, between conductors of other form. It is necessary, however, that the conductors should not be too near each other, or the effect will be marred by sudden disruption, as, for instance, through an interposed flame. 5. His invention consists in causing telegraphic communications from two or more instruments to pass

Digitized by Google

simultaneously through the same wire without interference, by the employment of electricities differing in quantity and intensity from each other, so as to be only capable of acting each one respectively upon a different class of instrument at the receiving station or stations; that is to say, for instance, a magneto-electric or other electric current to deflect a needle; a quantity current through the same wire to effect decompositions on chemically-prepared paper in another instrument; and a series of high intensity discharges through the same wire again to cause a succession of perforations in paper or other indications in a third instrument. The electricity employed for the foregoing purposes may be derived from any convenient source whatever, provided that it is adequate to fulfil the duties required of it. 6. His invention consists in the construction and use of a coil of the following description, which he considers to possess great advantages over those ordinarily used; namely, a core or cores of soft iron are wound with primary and secondary coils of insulated wire, on principles well understood, and over these are placed hollow cases or cylinders of soft iron (either in solid masses or in pieces) similarly wound with insulated wire: or plates of iron following in succession to each other may be used in the same way. He observes that the same principle also applies to hard steel when used in the development of magneto-electricity, and that he sometimes uses such arrangements of magneto-electric machines for the purpose, and the use of them consequently forms a part of his invention. In the accompanying engravings fig. 1 is a cross





section of his improved coil. The parts *a* represent iron; *b*, the primary coils; and *c* the secondary coils. A core of iron is first insulated circumferentially with gutta percha, and two large discs of gutta percha to form flanges are placed at its ends, and firmly fixed by heat, so as to form one unbroken covering of gutta percha from end to end. A primary wire is then wound from end to end upon the covered iron core. This being well insulated, two or three miles of secondary coil are superposed upon the primary. On this last a second coil of primary is wound. This last primary wire, being safely insulated, is covered over with a hollow cylinder of soft iron. Over this hollow cylinder comes another primary coil, then three or four miles of secondary again, then another coil of primary, and, lastly, another soft iron cylinder, so that in the coil here represented there is one iron core and two hollow iron cylinders, four primary wires, and two secondary wires. Every layer of wire must be well insulated from other layers and from the iron. He insulates the successive layers by three or four thicknesses of very thin gutta percha (in bands) followed by a thin covering of calico, also in a band, for each layer of wire. Other systems of insulation may also be used. The wire should properly be all wound the same way. The ends of each coil should be marked and made safe. The secondaries should be connected as a single coil when the machine is finished. The primaries will work better under general circumstances of action if connected as one bundle of four wires, and it will be found greatly to improve the power of the coil if the two primary currents next the core flow in one direction, and two other primary currents in the other direction. This follows from the general theory of magnetism, and its application will be seen where the details of the coil are altered in number or otherwise. The iron core and cylinders may be solid or in pieces, or otherwise. Figs. 2 and 3 show the manner in which a flame is deflected, and fig. 4 is a representation of paper marked at intervals by the deflected flame. The same apparatus applies to gases and vapours. *a*, *b*, are two brass *c* is a glass plate with an aperture therein, as knobs; seen more clearly in the detached view, fig. 3; *d* shows the candle and flame deflected; *e* is the Leyden jar; and *f* the discharging rod.

THE NATIONAL LIFE-BOAT INSTITTION.

During the past year the Royal National Life-boat Institution has incurred the following expenses, on either additional new life-boat stations, or the replacing of old boats, transporting carriages, and houses, by new ones: Norfolk—Cromer, £276 16s. 5d.; Mundesley, £223 9s. 5d.; Bacton, £377 11s. 11d.; Palling, £272 17s. 6d.; Winterton, £400 5s. 11d.; Yarmouth (two boats), £859 3s. 5d.; Suffolk—Lowestoft, £153 14s. 6d.; Southwold, £127 19s. Berwick, £73; Boulmer, £73; Alnmouth, £41; Whitburn, £247 1s., Hornsea, £44 12s.; Exmouth, £140 1s.; Appledore, £4; 12s.; Aberdovey, £138 3s. 1d.; Rhyl, £52 17s.; Penmon4 £72 15s.; Fleetwood, £140 1s.; Fraserburg, £255 2s. 2d.; Lossiemouth, £140 1s. Ireland—Newcastle County Down, £282 7s.; Dundalk, £191 1s.; Kilmore, £140 1s.; Carnsore, £187 8s.; Tramore, £322 18s. 9d.; Dungarvan, £191 1s.; and Ardmore, £81 11s. 5d. The Institution has also expended on the repairs, stores, alterations, and inspection of its numerous life-boats, boat-houses, and transporting carriages, £2,714 5s. 3d., making altogether a total of £8,265 3s. 9d. It has also granted, during the same period, £952 as awards for saving 427 persons from 64 wrecks on our coasts. A most satisfactory result, and clearly showing how much has been accomplished by the well-directed efforts which the Life-boat Institution has brought to bear on this humane cause. This great and national work has, however, only been accomplished by involving the society in a debt of £3,047, and an expenditure of £1,000 from its small reserved capital. Impelled by every feeling which we hold dear, to save a fellow-creature from an appalling death by shipwreck, one would suppose that the National Life-boat Institution had claims which came home to the hearts of every one and there pleaded for support and sympathy; and most particularly does this apply to the United Kingdom, which is so much indebted for so large a portion of its greatness and prosperity to its hardy seamen. In respect, then, of the Life-boat Institution, its objects being so truly national and philanthropic, we do not hesitate to recommend it earnestly, and on all occasions, to the support of those who are able to render it. That help was never more needed than at present, when, through the extraordinary exertions the society has made within the past few years, it has now eighty-one life-boats under its management. To maintain these boats in a state of thorough efficiency, a large permanent annual income is absolutely needed, if its humane mission is to be perpetuated. We feel assured that after this plain statement of facts relative to one of our most useful societies, we shall soon have the pleasure to report a very large increase to its permanent income.

LIST OF NEW BOOKS.

Barry's Theory and Practice of the International Trade of the United States and England, 8vo., cl., 6s.
Exhibition of Art Treasures held at Manchester in 1857: Report of the Executive Committee, royal 8vo., cl., 6s.

Webster's English Dictionary, new edit., 8vo., cl., 7s. 6d.

INDIAN ITEMS.

On the 15th ult., 64½ additional miles were opened by the Great Indian Peninsular Railway Company, which has now 177 miles in operation. The line now opened proceeds from Poonah to Kheirghaum, and thence to Patus, from which place it goes on to Decksal, and eventually will extend to Sholapore. This last portion will not, however, be completed for some months.——Government have sanctioned a proposed permanent establishment for the maintenance of the Vehar Water Works, on their completion, by the contractors at a monthly outlay of 2,500 rupees, as a charge for the management of the works.——An intricate network of telegraphic wire will soon cover the Indian empire. From Bombay, a coast line is being laid down viâ Nagotna, Severndroog, Rutnagherry, and Vingoria to Goa. This will join another line in course of construction, viâ Cochin to Cape Camorin, so that there will be an independent coast line the whole way from Calcutta to Bombay, viâ Madras and Manaar. North of Bombay, another coast line is being constructed viâ Bassein, Mahim, Demaun, and Bulsar to Surat, so that the latter place will communicate with Bombay direct instead of taking the circuit of Nassick. From Surat the line has already been completed to Kurrachee viâ Broach, Baroda, Ahmedabad, and Deesa; and from Kurrachee it is being pushed forward through the Punjaub to Lahore so that the latter will shortly be in direct communication with the western presidency. Another line is to be carried from Bombay to Nagpore viâ Poonah, Seroor, and Ahmednuggur, with a junction between Ahmednuggur and Nassick. From Nagpore a distinct line communicates with Calcutta viâ Benares, so that when Bombay is connected with Nagpore, there will be three separate wires communicating between Bombay and Calcutta, viz., viâ Madras, Nagpore, and Agra, besides a distinct line to Ceylon on the one side, and Lahore on the other (which are being carried out).

EXPLORATION OF AUSTRALIA BY BALLOONS.

Mr. H. Coxwell, of Tottenham, designer and constructor of the balloons ordered in this country by Mr. G. Coppin for use in Australia, gives the following account of the balloon explorations in Australia:—The balloons now at Melbourne were built simply for public amusement. The aëronauts, however, who went out in accordance with Mr. Coxwell's recommendation, were requested to make frequent meteorological observations, both in the higher region and lower currents, especially with a view of observing how far it is likely a balloon would be influenced by inland and return breezes. Mr. C. H. Brown, assisted by Mr. Dean, are now making the required observations, and from the accounts already received there appear to be good grounds for believing that certain reliable currents will facilitate the undertaking. As a matter of course, an expressly-built machine, of ample dimensions, will be requisite, together with every conceivable appliance, to afford a return journey by a diametrically opposite wind to that embraced at the outset. The party will also be provided with an improved and gigantic fire balloon, in a collapsed state, which can be inflated in the most desolate interior locality without gas, a reserve expedient, which in the event of injury or exhaustion to the parent machine, will provide the means for a second trip. Mr. Coxwell is also maturing a totally novel apparatus, to regulate the altitude of the exploring balloon, so as to avoid the continual loss of gas and power resulting from extreme variations in the atmosphere. This contrivance will bring the aërial vehicle under a larger amount of mechanical control. The expedition will be provided with a photographic apparatus for obtaining a series of bird's-eye views, the correctness of which will be invaluable. Viewing calmly the danger likely to accompany such an attempt, I do not think it can fairly be pronounced greater than that which attends an arctic voyage, or any other which originates from a desire to attain useful knowledge by intrepidity and personal risk.

METAL AND COAL TRADES, &c.

[FROM OUR OWN CORRESPONDENT.]

The Iron Trade generally—The Trade in South Wales—In Derbyshire, Yorkshire, and Lancashire—In Staffordshire—The Scotch Market—The Coal trade of the Country—The Labour Market—The general trades of the Country—The Hardware trades of Yorkshire and the Midlands—The Glasgow Pig Market—Prices of English Pigs—Copper and Tin.

Although there has not been so much doing in the past nine days or a fortnight as in the previous three weeks, yet the orders now on the books in most of the iron-making districts of the kingdom show a good demand for finished iron of all kinds, both for home and foreign consumption; such as will afford employment in some of the large works for several months. Less apprehension is entertained as to disturbances on the Continent than was the case a few

Digitized by Google

days ago. The fears of a disruption had begun slightly to check the progress which was setting in. It is the almost universal aspiration of the iron interest that peace may be maintained. If a war should not break out, a time of great prosperity is regarded as almost certain. The reports from America, upon which country the iron trade of Great Britain so greatly depends for customers, are very favourable as to the future prospects of that country. Its financial difficulties have been nearly all overcome, and there seems to be no question that as the season advances the advices from the United States will be of an encouraging nature, and if due care is exercised as to the price and quality of the iron sent from this country we may still look upon the Americans as our best customers. Having said this much in regard to the iron trade generally, it may be added upon the particular districts, that

In South Wales a slight advance has taken place in the price of bar iron, and the arrival of several fresh orders has increased confidence, which, it is anticipated, will be further strengthened as the spring advances. There is a tolerably good inquiry for France and Russia.

In the Derbyshire, Yorkshire, and Lancashire district the iron trade is said to be in a most healthy and satisfactory condition. The makers of the best brands of iron are well supplied with orders, but there is a difficulty experienced in disposing of inferior brands. Some large orders for railway iron have been taken by two houses in Yorkshire trade.

The South Staffordshire trade was reported on change at Wolverhampton on Wednesday to be no exception to the existing state of things generally. The first-class works are in full operation, and the makers of less note are steadily creeping up to them. Except at an advance large orders will not be accepted in South Staffordshire.

There is a quietness in the Scotch market which is causing the produce of that market, which is almost constantly oscillating, to move in favour of buyers.

The coal trade of the country is tolerably healthy, and remunerative rates are being got; but the supply is hitherto quite equal to the general demand. The labour market is gradually assuming a state of satisfactory quietude. The Wigan strike, which bore a serious aspect at the date of our last report, may be considered to have terminated. The men were expected to resume work yesterday (Thursday).

With respect to the general trades of the country, whose condition very much affect the metal trades in their early stages, it may be reported of the fabrics of Lancashire and Yorkshire, and Scotland, that, as a whole, they are in the midst of a period of healthy activity, attended with constant employment for the operatives, and good prices for the manufacturers.

The hardware trades of Yorkshire and the Midlands are tolerably well employed, and, except in a few branches, the workmen of Sheffield, of Birmingham, and of Wolverhampton, and of the dense district surrounding the two last-named towns, are working full time.

The Glasgow pig market is an exception to the other iron markets in relation to prices, as well as to the copper and tin market. English pig makers continue to ask higher rates; and copper and tin can only be purchased at the prices that may prevail at the time of delivery.

NOTES FROM THE SOUTH WEST.

[FROM OUR OWN CORRESPONDENT.]

Another Atlantic Cable—Drinking Fountains: Plymouth—South Coast Railway: New Works—The Peninsular and Oriental Company's Service: The Vectis—Water Supply of West Cowes—Experiments with Apparatus for supplying Water to Ships at Sea—The Narrow Gauge at Reading—An Adventurous Little Cutter—Warming Churches—West Somerset Railway—Extension of Railway Communication to Wells—The Bath and West of England Society—Cornwall Railway—H.M.S. Agamemnon—Docks for Falmouth: Important Movement—Loss of the Ceres Steamer—The Isle of Wight Railway—Dockyard Talk: The Mersey and the Howe—Adjustment of the Dispute between the Brighton and South Western Companies—Gunboats at Haslar.

The "Great Ocean Telegraph Company, Limited" have issued a prospectus in which they announce their intention to submerge, if they can find the necessary funds, a submarine cable from the Land's End to Halifax. The system which the Company propose to adopt is that of Mr. Thomas Allan, and lightness is the prominent feature of the proposed cable, which can be submerged without cumbrous paying-out gear from one vessel.——At Plymouth, a Mr. Bryant has addressed a letter to the Mayor announcing his intention to erect six drinking fountains and three cattle troughs at his own expense, only imposing the very fair condition that the water shall be supplied free of charge. *A propos* of this subject it may be stated, that four years since Liverpool did not possess one public fountain, while the number now amounts to 40. There is little doubt that this is one of the most practical efforts ever made in connexion with the temperance movement.——Some interesting facts are stated in the report just presented by the directors of that well-managed undertaking, the London, Brighton, and South-Coast Railway. It appears, that in order to satisfy the wishes of certain leading landowners in the district traversed by the Shoreham, Henfield, and Horsham line, application is to be made to Parliament to sanction a deviation in the northern portion of that branch, without, however, increasing the originally-estimated cost. As regards the southern portion, the directors state that the plans for carrying the line over the river Adur have now received the approval of the Admiralty, and the works are shortly to be commenced. The constant and heavy expense incurred in maintaining the timber viaduct which carries the Horsham line across the Ilfield Mill Pond renders its replacement by a solid embankment desirable, and the directors propose applying for parliamentary sanction to effect this object, and also to construct the short Spur line at Norwood, in accordance with certain arrangements made with the Mid-Kent Company. The extension to Leatherhead will shortly be ready for traffic, and a further extension to Dorking is contemplated.——Captain Hicks, late chief officer of the *Pera*, is appointed to the command of the *Nepaul*, a new screw steamer of 3,000 tons and 200-horse power. The engines of the *Vectis* are to be transferred to a larger ship. All these vessels are part of the magnificent fleet of the Peninsular and Oriental Company.——The West Cowes Local Board of Health propose to purchase the works of the Local Water Company, and have applied to Mr. Stephenson to act as arbitrator in the matter. Mr. Stephenson is unable, however, to undertake the office, but names two gentlemen whom he considers suitable. It is considered that the matter will soon be carried through.——The Board of Admiralty have been conducting a series of interesting experiments with the view of ascertaining by what apparatus the largest and best supply of water can be obtained for the use of ships at sea. (See article on Dr. Normandy's apparatus, p. 77.)——For some time a mixed broad and narrow gauge line has been laid down on the Great Western Railway, between Reading and Oxford, but from the want of a loop-line to connect the Great Western with the South-Eastern and South-Western Railways, goods could not be transmitted from the northern districts without being transferred by vans from one company's depot to the other. This impediment has now been removed by a short narrow-gauge loop being completed at Reading.——A small 28-ton cutter which sailed from Southampton on the 3rd November, arrived at Grenada on the 15th of December, after a very tempestuous passage. The name of the little craft is the *Royal Charlie*.——St. Peter's church, Clifton Wood, (Bristol,) is now reported to be effectively heated by a large descending stove, lined with Stourbridge bars, placed in the school-room under the church. From this stove the heat is conveyed to five ventilators in the floor of the church through as many pipes, covered with hair felt, which prevents the hot air contained in them from being neutralized by the outer cold, so that none of the heat is lost. The apparatus was designed and constructed by Mr. A. A. Harris, Marsh-street iron works.——The works on the West Somerset Railway which will connect the town of Taunton with the harbour of Watchet—and thence by steam communication with the Welsh coast—are to be shortly commenced, the directors having decided to proceed with the construction of the railway. The first sod will probably be turned in a week or two.——The quiet old cathedral town of Wells will be brought into connection with the turbulent world of railways next month.——The next meeting of the Bath and West of England Agricultural Society is to be held at Barnstaple, and the council has determined that the implement yard shall be open for exhibition on Monday and Tuesday, May 30 and 31. The system of prizes for implements has been abandoned, the council at the same time recording thanks to the judges in this department in past years for their valuable services. Mr. Thomas Dyke Acland has submitted a lengthy memorandum to the council embodying a proposition for extending the exhibitions of the Society to arts and manufactures. This memorandum stated that the agricultural implements exhibited at the Society's meetings had increased from 400 in 1852 to 1,100 in 1857; noticed improvements in the practical character of the implements; and added that the attendance of exhibitors from a distance had increased from 16 to upwards of 40 annually. A committee has been appointed to consider Mr. Acland's proposition, and if it is carried out—and there seems every probability that it will be—Exeter will be the town in which the proposed arrangement will be first reduced to practice.——The Cornwall Railway is now in such an advanced state, that the whole line from Plymouth to Truro (54 miles) is expected to be opened in a few weeks. The stations are all more or less advanced, the splendid Royal Albert bridge is nearly complete, and the permanent way has been laid on the Plymouth side as far as Saltash. From Truro to Dubwalls the permanent way is also completed, and from St. German's to within a short distance of Liskeard, while the rails are all prepared for the remainder, and as soon as the contractor, Mr. Ritson, can finish the St. German's viaduct, the whole will be ready for the passage of the locomotive. This line will of course supply through communication between London and Truro; and it is not a little singular that Cornwall should have been so long left without this advantage.——The boilers of H.M.S. *Agamemnon* have undergone a thorough repair, and she has been fitted with a new water casing.——An important effort is being made to promote the formation of docks at Falmouth. The tonnage of ships calling at the port—notwithstanding the want of any adequate accommodation beyond the natural advantages of the place—has more than doubled within the last nine years, 1,519 ships with a tonnage of 319,242 tons having entered in 1850, against 2,700 ships with a tonnage of 776,330 tons in 1858. The promoters of the proposed docks estimate that this trade would have been still further augmented if docks and slips had been provided; and it is also urged that as Truro is on the eve of being connected with the metropolis by railway, the mails will probably be restored to Falmouth, which is only ten miles from Truro, and is the most western point in the kingdom. Various attempts have from time to time been made, but without success, to induce the Government to re-establish the packet station at Falmouth, the removal of the mails to Southampton having been severely felt. An important county meeting has been held at Truro, at which Mr. T. H. Tilly entered into a variety of interesting details on the subject. It seems that the proposed tidal harbour is to comprise 12½ acres, and the close dock 8 acres, two graving docks to be constructed in the latter, and two patent slips in the former. The mouth of the tidal harbour is to be 350 feet wide, and it is proposed that the channel should be deepened to 18 feet at low water. This would require 9 feet of dredging, but the light character of the bottom—mud and shells—renders this part of the undertaking, it is said, comparatively easy. Mr. Tilly, referring to Southampton, drew a comparison with Falmouth, adverse to the former port. In Falmouth, he said, the entrance to the tidal harbour would be straight, and the passage from that harbour into the close docks inside it would be straight also—a great advantage for large vessels. The entrance to Southampton is at right angles, and the large steamers have to be warped round. The tidal harbour in Southampton is 16 acres in extent, and the dock inside is 10 acres, the breadth of the entrance being only 40 feet, as it was constructed when ships were not of their present capacity. The entrance to the Falmouth docks, on the other hand, is to be 80 feet. The average rise of tide is 18 feet springs and 13 feet neap, and it is intended to deepen the channel so as to make it 18 feet at low water. The beautiful harbour of Falmouth, (said Mr. Tilly, waxing eloquent), the outlet of the kingdom, the eye of the British Channel, had been allowed to run to decay, and silt up; and it was strange that it was considered national policy to allow the national harbours to fall into decay, while millions and millions were expended on experiments. Sir Charles Wood, he added, had stated that there never was but one opinion at the Admiralty that Falmouth was the proper packet station; "Make docks," Sir Charles is reported to have said, "and the steamers will come back to you." Mr. Abernethy, Admiralty Engineer—who is said to possess the rare faculty of keeping within his estimates—has been employed in surveying the port, and the expenditure for the proposed docks and other accessories is estimated at £200,000, against £800,000 expended at Southampton.——The *Ceres* steamer struck on the Lizard Point on Saturday afternoon, and foundered.——In the case of the proposed Isle of Wight Railway bill, the official examiner has decided that the standing orders of Parliament have not been complied with.——The *Mersey*, 40, a fine new screw frigate, is progressing rapidly in the steam-basin, Portsmouth Dockyard. Her engines have been tried with a favourable result, and the screw has arrived from the establishment of the Messrs. Maudslay. In consequence of its great size and weight (14 tons), it has been divided into three portions. The two blades are cast with flanges, and screw on to the centre boss with nuts and screws, so that they can be easily taken apart in case of accident. The tonnage of the *Mersey* is 4,000 tons, and she will be ready for her sea trial in February. She is being fitted on both sides with Clifford's patent boat-lowering gear.——The *Howe*, screw steamship of the line, will be launched in the course of the summer. The *Howe* will be a noble line-of-battle ship, and will carry 130 broadsiders and one pivot-gun. She will be rather larger than the *Duke of Wellington*. Great activity prevails in Pembroke Dockyard in getting ready for launching several fine vessels which are on the stocks; the first launch will take place in April.——It is stated that the unfortunate dispute between the Brighton and South-Western Companies, with reference to the Portsmouth traffic, has been amicably arranged; happily there does not seem to be such an appetite for law as formerly.——Forty gunboats are now hauled up on the slip at Haslar, and could within a few hours be made ready for sea.

NOTES FROM THE EASTERN DISTRICT.

[FROM OUR OWN CORRESPONDENT.]

East Suffolk Railway—Implement Makers and Prizes at Local Agricultural Exhibitions—Steam Plough Trial—Branch Railway at Lincoln—Embanking Marshes near Wells-next-the-Sea—West Ham Drainage: The New Metropolitan Works—Boston and Sleaford Railway.

They say the East Suffolk Railway and its tributary branches to Yarmouth and Lowestoft will be ready for traffic by the 1st of March.——The members of the Suffolk Agricultural Society have been discussing at their annual meeting the question whether they shall give prizes for implements and steam cultivators at the next exhibition. The implement makers have long been setting their faces against the expense and vexatious trouble which local societies have expected they should incur in the trial of implements for prizes; and an interesting letter was read to the Suffolk meeting from Mr. J. Allen Ransome, who observed:—"In the present state of the manufacture of the ordinary class of agricultural implements, their relative degrees of merit or superiority cannot be fairly settled unless much more time and tests by scientific instruments be applied than the ordinary facilities afforded by a local meeting will allow; and an award made under these circumstances of a specific prize marking one implement with a badge of superiority when many may be of equal or possibly of even superior merit, is unjust in its effect upon the competitors, and disadvantageous to the purchasers. This feeling is so strong with ourselves, and with several others who have been accustomed to contribute to exhibitions, that we should decline to exhibit as competitors where prizes were offered by local societies, while on the other hand we should be fully disposed to do our best to make such an exhibition as interesting as possible where the element of competition is avoided. It may not be out of place here to state that after very full correspondence and conference with the class of implement exhibitors, the Bath and West of England Society—which, with the exception of the Royal Society, is the largest and most influential of English agricultural societies—has come to the decision to abolish the principle of competition for prizes at their ensuing meeting. The only encouragement which we think lies within the scope of local agricultural associations to promote good exhibitions of implements, lies in the facilities they may afford for providing good places and covering for the machinery, and the material for the various machines to operate upon free of cost to the exhibitors; and possibly, if a society could afford it, facilities of transport from the ordinary railway stations and wharves to and from the place of exhibition. These remarks apply mainly to the general class of implements and machines to be acknowledged as standard implements, but are not intended to apply to any fresh development of agricultural machinery which may be entirely new in its application, as at the present time steam cultivation may be considered." A lengthened discussion took place on the subject, Mr. R. Garrett elaborating the views of Mr. Ransome on the part of the implement

Digitized by Google

makers; and Major Parker, on behalf of the farming element of the society, endeavouring to show cause in favour of adherence to a resolution passed by the association at a late meeting at Bury St. Edmund's, "that the committee should offer, if they think fit, a medal or reward to the best specimen of steam cultivation, if they deem it of sufficient merit." Steam, said the gallant major, had made rapid strides; Mr. Fowler's machine had received the approbation of the Royal Society, and the premium of £500 for the application of steam to land; and Mr. Smith had obtained a medal. Looking, too, at what took place at the Baker Street Exhibition, one was led to the conclusion, that public feeling was in favour of bringing steam into general use; and he must express his surprise that eminent agricultural implement makers should endeavour to throw cold water on a movement so fraught with good. Mr. Garrett, in reply, denied that he wished to do this, but urged that local societies would have immense difficulties in arriving at a proper conclusion on the subject. The Royal Society undertook elaborate trials, and if their decisions were impugned or reversed by local societies, the public mind could be only perplexed and disturbed. The trial of three or four steam machines would occupy a week, with endless expense to exhibitors, besides which the society did not know where to look for proper judges. The chairman (Sir Edward Kerrison) and Mr. Hawkins, supported the views of Mr. Garrett and Mr. Ransome; and jeventually Major Parker, who adhered to his proposition with some tenacity, consented to withdraw it—the chairman suggesting that the society should give all possible assistance to prove reaping machines, mowing machines, and steam cultivators; and that suitable fields and other facilities should with this view be provided. So the implement makers carried the day. ——A steam plough, manufactured at the establishment of Messrs. Clayton, Shuttleworth, and Co., of Lincoln, has been tested on the farm of Mr. Clarke, at Red Hall, in the presence of Mr. Amos, C.E., and a large party of agriculturists. Two men in the employment of Mr. Fowler, the patentee, took the management; and a local paper states that the work was accomplished in a satisfactory manner. ——At Lincoln a branch railway from the Midland station to the Great Northern has been visited by the Government inspecting-officer, and will soon be opened for traffic.—— Some operations have been for some time in progress for embanking an extensive tract of marsh land (700 acres), in the neighbourhood of Wells-next-the-Sea, Norfolk, the Earl of Leicester—descendant of "Coke, of Holkham," of world-wide agricultural celebrity—being the prime mover in the matter. The sea was shut out a few days since, on the completion of the embankment. Mr. Buxton has been contractor for the work.——With regard to the drainage of West Ham, it is stated that the works of the main outlet will be in all probability finished in the course of the summer. The Rev. A. J. Ram has directed the attention of the Local Board of Health to the circumstance of the great metropolitan sewer about to be constructed coming across the sewer of this district. The centre line of the sewer at Stratford will pass through Waterworks-row, and will diverge in the direction of West Ham Abbey. Some slight deviations will probably be made from the original plan in the sewer in the Stratford district, with the view of meeting the levels of the outlying districts of the London docks, and adjacent neighbourhoods. The sewer, it is stated, will materially interfere with the high-road east of Peg's-hole bridge, extending to near Christ church, Stratford Marsh, which will, it is said, be necessarily raised from 12 to 14 feet.——The new railway from Sleaford to Boston will be opened in the summer, or possibly late in the spring.

CURRENT EVENTS

IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

[COMPILED BY OUR OWN CORRESPONDENT.]

Opposition to the South-Eastern Harrogate Stray Scheme —St. Helen's Canal Company and the London and North Western—The Line from Garston to Liverpool—Launch of a large Iron Screw Steamer—Operations on the Worcester and Hereford Railway—Fearful Boiler Explosion —Meeting of Collier Delegates at Wigan—Protest against the Truck System by South Staffordshire Colliers—The War between the Glass Blowers and their Employers— The Wages Question of the Factory Operatives of Lancashire, Yorkshire, Derbyshire, and Cheshire—Decision of the Judge of Preston County Court as to Damage of Machinery.

THE owners of Harrogate Stray resolved that the most active measures ought to be taken to prevent the North Eastern Railway Company from obtaining possession of any portion of the Stray, for the purpose of converting it into a line of railway. A borough meeting at Knaresborough has resolved to oppose the scheme in Parliament.——The long-pending negotiations between the St. Helen's Canal Company and the London and North-Western Railway Company have at length been brought to a very satisfactory conclusion. The London and North-Western Railway have agreed to rent that portion of the line extending from Warrington to Garston. It is reported that the rental will be fixed at £9,000 for the first year, £10,000 for the second year, £12,000 for the third year, the lease being for three years.——The bill for the extension of the line from Garston to Liverpool will be brought forward in Parliament early in the ensuing session. The branch line from St. Helens to Eccleston is rapidly approaching to completion; when finished it will greatly facilitate the coal and stone trade of that district.——A large iron screw-steamer has been launched at Newcastle-upon-Tyne. She is named the *Empress of India*, and has been built with unprecedented strength, to be used in the whale fishing trade in the Arctic Seas. After being built under the special inspection of Lloyd's surveyors, she is classed 12 years A1., and in addition is fortified with cellular chambers, on the principle of the *Great Eastern*, besides double plating forward, the internal plates of which exceed 30 feet in length. Indeed, it is almost impossible to conceive anything stronger. She is fitted with two large permanent tanks, and other moveable tanks equal to a capacity of six hundred tuns of oil. In addition to the machinery, the vessel is full rigged. When the vessel is ready for sea there will be upwards of 100 men on board, the largest crew of any vessel in that trade. The engines are of 100-horse power. The screw is so constructed that it may be disconnected, and raised on deck in a few minutes.——The construction of the Worcester and Hereford Railway has so far progressed that the portion between Worcester and Malvern is expected to be opened at Midsummer. From the tunnel near the Shrub-hill station of the Oxford, Worcester, and Wolverhampton, and Midland Railways, to the Foregate-street, the line will pass over a huge embankment of brick and earthworks. The Foregate will be spanned by a handsome open ironwork bridge, at an altitude of about 20 feet, the piers to support which are nearly, if not quite completed. A succession of bridges then carries the line on to the river, and here a graceful iron structure of two arches, rising 47 feet above the water-level, is being constructed. The length of this bridge will be about 250 feet. The remainder of the line through Henwick and Malvern involves no work beyond the ordinary character, and here about a quarter of the permanent way is already laid. The boring of the tunnel through the Malvern range of hills is a most difficult and protracted undertaking, but there appears no doubt that in time it will be successfully accomplished.——A most fearful boiler explosion occurred on the Brunton and Shields Railway on Tuesday. The coals are sent down this railway by incline to the staiths in the Tyne, and a man named William Brunton was in charge of a standing engine about a mile and a half from Percy Main, when the boiler exploded with fearful force. The engine-house was completely demolished, and Brunton was buried under the roof and ruins of the building, whence he was dug out, dreadfully mutilated, an hour and a half afterwards. There was considerable damage of property, with miraculous escapes. Deficiency of water is supposed to have occasioned the calamity.——Another pit-chain has broken, near to Wolverhampton, occasioning the death of one man and the expected decease of a second. A long-standing defect in a link in the chain has been discovered.——At a meeting of collier delegates at Wigan on Tuesday, it was resolved to cease the strike.——The South Staffordshire colliers assembled at an open-air meeting on Monday in large numbers, to protest against the truck system practised by some of the iron and coal masters there.——The war between the glass-blowers and their employers continues to be waged with much determination on either side.—— The factory operatives in the manufacturing districts of Lancashire, Yorkshire, Derbyshire, and Cheshire, have for some time past contemplated a general movement for securing an increase of wages, considering that the prosperity of the cotton trade would amply justify them in such a course. The spinners and self-actor minders have taken action in the matter, and the general body representing the four counties above mentioned, has made a draft of a memorial to the employers, setting forth the views of the workers on the subject. The agitation assumes entirely the character of a request to the employers; in many instances the amount of the advance of wages desired is not even named. In case of a refusal, there is no intention, we believe, of attempting to gain the object by a "strike." From the prevalent feeling among the manufacturers and spinners, it is not improbable that an increase will be generally conceded. The power-loom weavers contemplate a similar movement, characterised by exactly similar means.——The Judge of the Preston County Court has ruled that an operative who damages machinery by neglecting to properly attend to it must pay for the damage sustained by the master. In this case an operative had neglected to oil his mules sufficiently.

PROVISIONAL PROTECTIONS.

Dated December 3, 1858.

2766. E. S. Jones, of Marylebone-st., Golden-sq., Professor of Music. Improvements in cornets, trumpets, horns, and similar musical wind instruments.

Dated December 21, 1858.

2916. A. S. Beliard, of Bordeaux, Hatter. An improved machine for pumicing felts, tissues, and skins.

Dated December 27, 1858.

2954. J. Radley, of Dublin, Hotel Keeper. An improved cooking apparatus.

Dated December 30, 1858.

2984. H. C. Vion, of Paris, Civil Engineer. A new mode of obtaining atmospheric electricity, and terrestrial electricity, and its industrial applications, and in apparatus for the same.

Dated December 31, 1858.

2999. J. H. Johnson, of Lincoln's-inn-Fields. Improvements in the manufacture or production of boots and shoes or other coverings for the feet, and in the machinery and apparatus employed in such manufacture. A communication.

3001. M. D. Wyatt, of Guildford-st., Russell-sq., Architect. Improvements in tiles and tessaræ and other wall coverings, and in the means of securing the same to walls and buildings.

3003. J. Lees, of Park Bridge, near Ashton-under-Lyne, Roller Maker, and W. Heap, of Ashton-under-Lyne, Tool Maker. Improvements in machinery for punching square holes in the ends of rollers and other articles.

3005. F. W. A. Casper and G. H. Schmahl, of Paris. Using spart or Spanish broom in manufacturing seats of all descriptions.

3007. J. H. Johnson, of Lincoln's-inn-fields. Improvements in the manufacture or production and casting of steel, and in the apparatus employed therein. A communication.

Dated January 1, 1859.

1. J. T. Pitman, of Gracechurch-st. An improved mode of making and fitting bungs to casks and other vessels. A communication.

2. H. C. Traphagen, of New York. Improvements in skirts for ladies.

3. A. Anderson, of Lancaster, United States. An improvement in governors for machinery.

4. B. J. Gosteau, of Paris, Merchant. An improved grid-iron which may form a complete cooking apparatus.

5. J. E. Drouot, of Paris, Baker. Improvements in bakers' ovens.

6. W. Footman, of Water-st., Strand. Improvements in breaks for retarding and stopping railway trains, carriages, or other vehicles.

7. J. Oliver, of White Bank, near Chesterfield. Improvements in lubricators for steam-engine cylinders.

9. J. Garforth, of Dunkinfield, Engineer. Certain improvements in steam engines.

10. H. Ashworth, of Littleborough, Manager. Certain improvement in power looms for weaving.

11. R. Smith, of Beith, Ayr, Wright. Improvements in casting, applicable to printing surfaces, and for other purposes.

12. P. E. Guérinot, of Paris, Jeweller. Improvements in the application of an apparatus to railway locomotives, waggons, and carriages, for the purpose of lessening the effect of concussion in the event of collision.

13. W. Eccles, of Surrey-st., Strand, Master of Arts. Improving the machinery or apparatus for regulating the tension of the twist threads or warp whilst it is weaving in power looms into cloth.

15. A. Prince, of Trafalgar-sq. Improvements in the construction of cylindrical presses. A communication.

16. W. A. Von Kanig, of Leipsic, Gentleman. Improvements in machinery or apparatus for digging and cultivating land.

17. J. Harris, of Hanwell, Engineer. Improvements in apparatuses for regulating the pressure and flow of steam, water, and other fluids.

19. G. Skinner and J. Whalley, of Stockton-on-Tees, Earthenware Manufacturers. Improvements in the manufacture of ornamental and other tiles, and other similar articles.

20. J. Brown, jun., of Rotherham, Ironfounder. Improvements in buffers, draw springs, and bearing springs.

21 G. T. Bousfield, of Brixton. Improvements in machinery for forming dough into cakes or bread crackers. A communication.

22. A. L. Lévêque, of Paris, Gentleman. An improved apparatus for subduing or stopping runaway or restive horses.

23. J. B. Morgan; of Liverpool, Cotton Broker. Improvements in propelling navigable vessels.

Dated January 3, 1859.

24. J. Luis, of Welbeck-st. New economical candles. A communication from A. Michaut.

25. R. Tempest and J. Tomlinson, of Rochdale, Machine Makers. Improvements in certain machines for preparing cotton and other fibrous materials.

27. C. B. Blyth, of Dundee, Mill Manager. Improvements in machinery for preparing and treating jute, hemp, flax, and other fibrous materials.

29. W. Renton, of Leeds, Cloth Dresser, T. Renton, of Leeds, Millwright, and W. Binns, of Leeds, Cloth Finisher. Improvements in raising the nap or pile of textile fabrics.

30. J. Furnival, of Leamington, T. Furnival, of Cobridge, J. Derbyshire, of Longton, and F. J. Emery, of Burslem. Improvements in apparatus for supporting articles of china and earthenware in kilns and ovens.

Dated January 4, 1859.

31. L. J. Higham, of Edmund-pl., City, Mechanic. Improved means for obtaining submarine electrical conduction.

32. J. Buchanan, of Greenock, Gentleman. Improvements in oil cans or lubricating apparatus.

33. J. B. Joyce, of Bradford, Machine Maker. Improvement in means, machinery, or apparatus, applicable to wool combing.

34. W. Hood, of Upper Thames-st., Iron Merchant. Improvements in racks and water cisterns for stables.

35. A. Bedborough, of Southampton, Architect and Surveyor. An improved chimney cowl and ventilator.

36. C. de Forest, of Leicester-sq., Gentleman. An improvement in the manufacture of springs for carriages, and other uses. A communication from C. Goodyear, jun.

Dated January 5, 1859.

37. F. Clark, of King-st., Bloomsbury, Turner. Improvements in connecting knobs and handles to the spindles of locks and latches, and other articles of a like nature.

38. W. Draper, of Brixton. Improvements in machinery for printing on paper and other fabrics.

39. J. Howard, of Bedford, Agricultural Implement Maker. An improved construction of lever-neck plough.

40. R. Rumney, of Manchester, Manufacturing Chemist, and W. S. Macdonald, of the same place, Mechanic. Improvements in printing and dyeing woven fabrics and yarns or threads.

41. A. V. Newton, of Chancery-lane. An improvement in the process of, and improved apparatus for, separating metals from their ores. A communication from L. Solomon, of New York.

Dated January 6, 1859.

43. J. Kirkman, of Bolton-le-Moors, Manufacturer, and I. Grundy, of the same place, Cotton Spinner. Improvements in certain kinds of bed covers or counterpanes, and other textile fabrics of similar character, and in the mode or method of weaving the same.

44. G. Bury, of Everton, near Liverpool, Overlooker. Improvements in part or parts of apparatus commonly used and applied for effecting the pick in power looms for weaving.

Digitized by Google

45. H. G. Coombs, of Union-st., Borough, Ironfounder. An improved method of constructing railings, bars, gates, gratings, columns, and all other builder's work, of a like nature or description.

46. E. T. Hughes, of Chancery-lane. Improvements in machinery or apparatus for preparing cotton and other fibrous materials to be spun. A communication from C. Vallée.

47. W. Renton, of Leeds, Cloth Dresser, T. Renton, of Leeds, Millwright, and W. Binns, of Leeds, Cloth Finisher. Improvements in finishing woollen and other fabrics.

48. J. Aspinall, of Great Tower-st., Civil Engineer. Improvements in machines for the manufacture of bolts, rivets, and spikes.

49. J. H. Johnson, of Lincoln's-inn-fields. An improved textile fabric, applicable to the manufacture of varnished cloths, and to other purposes. A communication from A. P. Roger.

50. J. H. Johnson, of Lincoln's-inn-fields. Improvements in machinery or apparatus for boring or piercing rocks, applicable also to the dressing or working of stone, and as a power hammer generally. A communication from G. Sommeiller.

Dated January 7, 1859.

51. W. Spence, of Chancery-lane. Improvements in the mode of taking photographic pictures on wood. A communication from C. B. Boyle.

53. E. Heywood, of Halifax. Improvements in weaving.

55. G. K. Geyelin, of London, Civil Engineer. Regulating gas burners, which he calls the "Universal Gas Burner Regulator."

57. J. Paterson, of Wood-st., City, Warehouseman. An improvement in bands and belts for the waist.

59. W. E. Newton, of Chancery-lane. Improvements in machinery for winding, twisting, and doubling fibrous materials. A communication from L. B. Duboc, jun.

Dated January 8, 1859.

61. C. F. Vasserot, of Essex-st., Strand. An improved chain and bucket pump. A communication from A. X. Dubrulle-Chevalier.

63. T. B. Hubbell, of Castle-st., Manufacturer. An improved trap for rabbits, rats, mice, and other like animals and vermin. A communication from C. B. Hubbell.

65. A. W. Williamson, of University College. Improvements in condensers for steam engines and other purposes.

67. W. Clark, of Chancery-lane. Improvements in purifying natural phosphates of lime. A communication from E. C. Martin.

69. J. T. Forster, of Kensington, Gentleman. Improvements in bed births, applicable for bunks, hammocks, cots, and other fixed and moveable sleeping places.

71. W. A. Lyttle, of General Post-office, Ireland. Taking the place of springs in many, if not all, of the combinations into which they enter, and also for equilibrating a varying force or weight.

Dated January 10, 1859.

73. L. A. Normandy, jun., of Judd-st. Improvements in the process of distilling and clarifying resinous substances. A communication.

75. F. Lehr, of Hoboken, New Jersey. Improvements in machinery for manufacturing metallic ribs for umbrellas, parasols, and other articles.

77. J. White, of Finchley, Surgeon. Improvements in cleansing or purifying air, and in increasing or reducing the temperature thereof, and in the application of air so treated to sanitary and other uses.

Dated January 11, 1859.

79. E. Agneni, of Devonshire-st., Bloomsbury, Painter. Increasing the effect of decorative pictures, landscapes, drawings, and prints, through looking-glasses.

81. J. Biers, jun., of Kentish Town, Coach Maker. A self-acting carriage wheel break.

83. W. Tillie, of Londonderry, Shirt Manufacturer. An improvement in the manufacture of shirts and shirt fronts.

85. B. J. Rubenstein, of London, Dentist. Improvements in dentistry.

87. C. W. Siemens, of John-st., Adelphi. Improvements in supports for electric telegraphic line wires, and in tools or apparatus to be used in the construction of such supports, part of which improvements are applicable to the joining of pipes and other articles.

89. N. P. Burgh, of Sheerness, Engineer. Improvements in steam engines.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

2071. W. Thomson. Bleaching.
2088. S. St. C. Massia. Fire Places. A communication.
2102. C. Hadley. Omnibuses, &c.
2108. J. B. Beasley. Guns.
2110. H. W. Grylls. Laying down cables.
2113. H. Barrow. Cartridge boxes.
2114. H. Firmin. Cleansing chaff, &c.
2119. L. de Pariente. Gas burners. A communication.
2120. J. C. E. Malvesin. Tubes, pipes, or mains.
2121. J. Bethell. Treating pyrites.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table:—

STEAM ENGINES, &c., 1200, 1214.

BOILERS AND THEIR FURNACES, 1169, 1206.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c. 1151, 1183, 1191, 1200, 1203, 1206.

SHIPS AND BOATS, including their fittings, 1161, 1163, 1169, 1173, 1216.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1182, 1184, 1196, 1198.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1150, 1192, 1198, 1207.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1155, 1157, 1158, 1174, 1179, 1183, 1186, 1190, 1193, 1209, 1210, 1217.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. 1160, 1176, 1180, 1181, 1199.

LIGHTING, HEATING, AND VENTILATING, 1195.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1147, 1153, 1156, 1211, 1212.

METALS, including apparatus for their manufacture, 1148, 1149, 1162, 1171, 1188, 1189.

CHEMISTRY AND PHOTOGRAPHY, 1187, 1217.

ELECTRICAL APPARATUS, 1152.

WARFARE. 1159, 1164, 1172.

LETTER PRESS PRINTING &c., *None*.

MISCELLANEOUS, 1151, 1154, 1160, 1166, 1167, 1168, 1170, 1175, 1177, 1178, 1182, 1194, 1197, 1201, 1202, 1204, 1205, 1211, 1213, 1215, 1217.

1147. J. H. JOHNSON. *Improvements in curtain rods.* (A communication.) Dated May 22, 1858.

This rod has spiral grooves formed upon it, and may be made to rotate upon its longitudinal axis by barrels having cords wound round them in opposite directions. The curtain rings are each contained in a separate groove of the series formed by the spiral, so that on turning the rod they will run along its surface in either direction. *Patent completed.*

1148. A. P. PRICE. *Improvements in the treatment and smelting of certain argentiferous or silver ores.* Dated May 22, 1858.

This consists in combining silver ores when in a fine state of division with bituminous coal, or with coal or carbonaceous matter and bituminous coal, or with coal or carbonaceous matters and pitch, tar, asphalte, or bitumen or other bituminous matter (such materials being by preference employed in a state of division), and subjects such mixtures to compression. It further consists in the admixture of suitable fluxes with the silver ores, together with the carbonaceous or bituminous tarry or pitchy materials, also in the use of all such materials for the reduction of the silver ores in the manufacture of silver in a cupola blast, or other suitable furnace. *Patent completed.*

1149. A. P. PRICE. *Improvements in the treatment of certain zinc ores and compounds of zinc, and in the manufacture of zinc and oxide of zinc.* Dated May 22, 1858.

To render more advantageous the use of calcined ores of zinc, or of artificially prepared oxides of zinc for obtaining metallic zinc, the patentee proceeds as follows:—He by preference reduces the ore to a fine state of division, and subjects it to a process of calcination or oxidation. He then mixes calcined blendes, carbonates or oxides of zinc, oxides of zinc when artificially obtained or prepared, or metallic zinc, with bituminous coal, with coal or carbonaceous matter and bituminous coal, or with coal or carbonaceous matter and pitch, tar, asphalte, or bitumen, and subjects such mixtures to pressure. It further consists in the admixture of suitable fluxes. Also in the use of all such materials, in any suitably arranged blast cupola, or other furnaces for obtaining metallic zinc or oxide of zinc. *Patent completed.*

1150. G. WHITE. *A liquor suitable for manufacturing beverages, and for culinary purposes.* (A communication.) Dated May 22, 1858.

This consists in forming by means of tartaric acid dissolved in any suitable solvent such as water, spirits of wine, or others, a liquor to which flavour is imparted by mixing therewith any suitable essential oil, such, for instance, as the oils of lemon or orange peel, neroli, or others, and to which may be added cane, grape, beetroot, or other suitable sugar, thus forming a concentrated liquor for instantly preparing refreshing beverages by being mixed with water, wine, arrack, tea, or other drinks, or which may be used as a condiment for culinary purposes. *Patent completed.*

1151. A. ELLISSEN. *Improvements in signalling in railway trains.* Dated May 22, 1858.

The patentee claims an adaptation of tubes for operating pistons, bells, and other signals for signalling in railway trains. The invention is not described apart from the drawings. *Patent completed.*

1152. I. BAGGS. *Improvements in electric telegraphs, and in the apparatus employed therein and therewith, parts of which are applicable to other electrical purposes.* Dated May 22, 1858.

This invention is described at page 78 of this Number. *Patent completed.*

1153. G. F. PARKE and J. BRIANT. *Improvements in bonnets.* Dated May 22, 1858.

The body of the bonnet consists of four pieces, two of which form the head piece, and two the sides. The head

Digitized by Google

pieces are cut of such form that when united at a certain line they retain the required form. *Patent abandoned.*

1154. W. CLARK. *Improvements in machinery or apparatus for moulding articles of cement.* (A communication.) Dated May 22, 1858.

This relates to manufacturing paving blocks or squares, flags, bricks, sculptured ornaments, pipes for gas, water, &c. Plain articles are conducted into a mould-frame which shapes them. They are taken out of the moulds by a machine, having a lever, cam, and treadle, which removes the bottom of the mould. For pipes, the inventor uses a hollow mould having a conical part which forms the collar or socket. In the centre of this tube is another tube having a longitudinal hinge which forms a core. To remove the pipe from the mould the moveable axis is removed from the hinges, which allows of the core being withdrawn. The pipe is then taken out of the exterior mould all in one piece. *Patent abandoned.*

1155. R. HATTERSLEY. *Improvements in looms for weaving.* Dated May 20, 1858.

This relates to looms with rotary motion shuttle-boxes, and consists, 1, In the use of portable hooks for connecting the levers acted upon by the cam on the picking shaft with the levers which operate the rotary shuttle boxes, such hooks being connected to the boxes at the time only when the boxes require to be changed, by taper rods alone or in connexion with cams or levers which are operated by the jacquards. 2, In having the first-named levers so attached at the fulcrum end as to be capable of lifting therefrom if the shuttle does not box, or go properly into the box, which levers are so constructed as to act upon the strap guide and stop the loom. 3, In working the rotary shuttle boxes by right and left hand ratchet wheels and catches, which catches are kept out of gear therewith at all times except when acted upon by the before named levers through rods for turning or changing the boxes. 4, In applying a friction roller or pulley to the spring pin which acts on the star wheel attached to the rotary boxes for holding them in position. 5, In the use of friction rollers or pulleys at the end of the shuttle boxes for pushing the shuttle back into the box. 6, In having a groove formed in the bottom of each shuttle box for the picker tang to move in to keep the picker steady. *Patent completed.*

1156. J. EDWARDS AND T. LOVERIDGE. *Improvements in the manufacture of buttons and other fastenings for articles of dress.* Dated May 24, 1858.

This relates to making double shell trouser buttons. The front shell is so made that the back shell may be brought over the front, and form a rim round the button. Part of this button is coated with varnish to protect the metal from the action of the atmosphere. *Patent abandoned.*

1157. M. STEVENS. *Improvements in machinery for pulping straw and other vegetable fibres.* Dated May 24, 1858.

The patentee employs a roller with plates secured therein at intervals, so as to leave between every two plates a groove or space. Or he takes a plain roller with grooves along the breadth thereof, and causes this roller to rotate in a bed composed of a semi-cylinder, of a diameter and form corresponding with, but little larger than, that of the roller. The roller is kept clear of the bed, and by shifting bearings, the distance between the roller and bed can be regulated. There is a cover to the pulper, and the fibre is fed in between the roller and bed by an inclined shoot. The roller rotating rapidly reduces the fibre to an even pulp by the rubbing action kept up upon them between the surfaces of the roller and bed. *Patent completed.*

1158. J. SCHOLFIELD and W. CUDWORTH. *Certain improvements in machinery or apparatus for preparing, doubling, and twisting cotton, and other fibrous substances.* Dated May 24, 1858.

This relates principally to the "tubes" or hollow spindles of "dyers' frames." It consists in closing and tapering the delivery end of these tubes, and forming holes in the sides of them, in such a position that the sliver may pass from the inside of the tube to the outside and thence to the inside again, as many times as required, and be finally delivered to the bobbins from one of the holes in the opposite side of the tube, by which a more permanent twist is given to the sliver. The tubes and connected apparatus are driven in the ordinary manner. *Patent abandoned.*

1159. W. HARDING. *Improvements in revolver fire-arms.* Dated May 24, 1858.

Here the cylinder turns on two centres. The body of the firearm is in two pieces, one fixed to the stock and the other made part of the barrel. The two pieces are readily separated in order to take out the cylinder. The lock or action is thus made:—On the trigger is a projection which, when the trigger is drawn back, acts on an incline on the hammer, and thus raises the hammer. When the projection on the trigger comes to the end of the incline the hammer escapes, and by falling explodes the cap, the trigger then returns by the action of its spring, the incline receding. When the hammer has been raised a short distance by hand certain notches lock together, and the hammer is then held at half-cock. If the hammer is raised a little higher than it can be raised by pulling the trigger, then the end of the projection on the trigger drops into a notch on the projection from the hammer, and holds it at full-cock. By pulling the trigger the projection from it is lifted, and the hammer falls and explodes the cap. *Patent completed.*

1160. G. HAMILTON and W. H. NASH. *Improvements in locks and keys.* Dated May 24, 1858.

Here a lock is constructed of two or more discs which turn round the drill pin, and a portion of the circumference of each of the discs projects beyond the case of the lock, and serves as a bolt. A portion of each of the discs is cut away around the hole in its centre, and projections on a key enter the space so formed, which projections act on the discs and move them round. Other forms of lock are also modified by the inventors. *Patent abandoned.*

1161. P. A. GALITZIN, S. SOUSCHKOFF, and P. E. GUERINOT. *An improved apparatus intended to prevent boats or ships to be destroyed and sunk when running full against each other.* Dated May 25, 1858.

This consists of iron rods having one end pointed, whilst the other is provided with a large wooden disc or buffer. The rods run and may slide through guiding pieces placed fore and aft, and can penetrate into the hull of the boats or ships provided with them when the buffers meet with an obstacle. *Patent abandoned.*

1162. J. A. PHILLIPS. *Improvements in the production of zinc, lead, copper, and silver from ores containing these metals.* Dated May 25, 1858.

This consists in roasting the substances either in heaps, kilns, or furnaces. The ores are subsequently heated for the zinc they contain, either by the English, Belgian, or Silesian process. The residues withdrawn from the reducing apparatus are afterwards fused either in a reverberatory or blast furnace, with or without the addition of plumbiferous matter. The copper is obtained in the form of matt, whilst the lead and silver are procured as an alloy. *Patent abandoned.*

1163. W. WEBSTER. *Improvements in machinery for the propulsion of vessels.* Dated May 25, 1858.

This invention is not described apart from the inventor's drawings. *Patent completed.*

1164. G. W. MORSE. *An improvement in fire-arms, and cartridges to be used therewith.* Dated May 25, 1858.

This relates to firearms loaded at the breech, and adapted to the use of a metallic cartridge case, and consists in combining a percussion rod in a moveable breach piece with a sliding bolt, so that the lock in the act of firing shall both lock the breach piece and fire the charge. It also consists in the use of the globular surface on the front end of the moveable breach piece in combination with the cylindrical cartridge case for preventing the escape of gas at the joint, also in the use of the lever as described, for retracting the cartridge case from the barrel. Also in the use of cartridge cases as described, for preventing all escape of gas at the breach joints. The invention is not fully described apart from the drawings. *Patent completed.*

1165. W. WEBSTER. *An improved method of rigging vessels.* Dated May 25, 1858.

This invention is not described apart from the inventor's drawings. *Patent completed.*

1166. C. F. D. MONNIN. *Improvements in the manufacture of rivets, screws, spikes, pins, and nails, and in machinery for that purpose.* (A communication.) Dated May 25, 1858.

This invention relates to modes of, and machinery for, raising or stamping the heads of rivets, screws, spikes, pins, and nails, for turning and nicking the heads of screws, and for threading or worming screws, and also for introducing, feeding, transporting, and removing the screws or blanks into or from one part to another of machines adapted for such purposes. In raising the heads of screws and rivets and similar articles by compression, especially when the heads are of hemispherical form, the metal is apt to be cracked and split, and the heads rendered imperfect or spoiled. This defect is obviated by raising the head at two or more operations. This invention is not susceptible of being intelligibly described apart from the drawings. *Patent completed.*

1167. C. F. VASSEROT. *An improved construction of rails for fences and gates.* (A communication.) Dated May 25, 1858.

This consists in giving either a concave cross T or V shape to the bars, cross bars, and posts, and by rivetting the same together. *Patent abandoned.*

1168. P. GRIFFITHS. *Improvements in manufacturing bushes for firing drums on shafts, and other similar purposes.* Dated May 25, 1858.

These bushes are formed in pieces of the exact form that is required by casting them in suitable iron moulds, by which all turning and cutting into pieces is dispensed with. *Patent completed.*

1169. G. ALTON and J. FERNIE. *An improvement in the construction of steam boilers and other vessels capable of resisting pressure, and in the manufacture of plates for the same.* Dated May 25, 1858.

This invention consists in forming boiler-plates with thickened edges bent into an angular or flanged form. See MECHANICS' MAGAZINE, page 592, No. 1845, Vol. 69. *Patent completed.*

1170. J. F. BELLEVILLE. *An apparatus for indicating the work of pumps.* Dated May 25, 1858.

This consists in leading from the suction pipes of suction pumps, or from the eduction pipe of force pumps, or from both, a pipe open to the suction or eduction pipe at one end, and provided at the other with an indicator, acted upon by the pulsations of the liquid, through a flexible diaphragm, and showing upon a dial the force and frequency of the pulsations. The patentee sometimes fixes a stop-cock in the indicator tube. *Patent completed.*

1171. J. COURAGE. *Improvements in furnaces for smelting and calcining.* Dated May 25, 1858.

This consists in so constructing these furnaces as to be enabled to regulate and distribute the heat therein. The patentee uses a hanging or other bridge, perforated or not, and employs one or more dampers which can be moved to or towards the bridge, to shut off entirely or partially the flame and products of combustion from passing to the melting pots. The same object may also be effected by dispensing with the bride and employing dampers only. *Patent completed.*

1172. W. E. NEWTON. *Improvements in breech-loading fire-arms, and cartridges for the same.* (A communication.) Dated May 25, 1858.

This consists, 1, in using a breech which closes by a forward movement of the barrel, and a ball which fits with its bare lead in contact with the bare metal, so that by closing the breach the ball will be forced forward into the rifle grooves of the barrel; 2, in placing the lock within a hinged unchambered breech piece; 3, in the use of an adjustable screw at the rear of the breech, to force the breech up to a tight joint with the barrel; 4, in the construction of the vent plug with a spring lip or lips, or an elastic mouth, which will be opened by the explosion of the priming, but be closed by the explosion of the charge; 5, in certain methods of constructing an elastic metal lip to the breech or barrel, which will close perfectly the joint between them; 6, in providing for a tight joint at the breech by applying a piece of india-rubber in the form of a piston-packing in the rear of the barrel, protected from the fire, so that it will be compressed against the breech by the explosion and expand itself laterally against the barrel to prevent escape of gas; 7, in an improved metallic cartridge, for firing paper cartridges repeatedly; 8, in a contrivance which is attached to a moveable breach for withdrawing the shells of the exploded metallic cartridges from the barrel by the act of opening the breech. *Patent completed.*

1173. R. C. WITTY. *Improvements in protecting ships of war and land batteries and fortifications from injury from shot and other projectiles.* Dated May 26, 1858.

This consists in applying blocks of vulcanised india-rubber to the sides of the ship of war, or to the face of the battery or fortification to be protected. The blocks are hollow, and of a cylindrical form, and are applied so that the axes of the cylinders run parallel with the side or face to be protected. Over the cylinders, slabs of vulcanised india-rubber are fixed, so as to produce a flush surface to receive the first shock of the shot or other projectile, and this shock it transfers to the cylinders underneath, which act as springs modifying the intensity of the blow, and spreading its action over a considerable surface. *Patent abandoned.*

1174. F. A. GATTY. *Improvements in treating cotton or cotton yarns and fabrics when dyed with certain colours.* Dated May 26, 1858.

After the yarns and fabrics have been printed or prepared with aluminous mordants in the ordinary way, and dyed with any preparation of madder, they are immersed in a solution of a salt which becomes acid by heating for producing an acid reaction upon them. He prefers a solution of alum. When the fibres are well impregnated, the excess of liquid is removed by a hydro-extractor, and the prepared materials are dyed and then heated to from 180 deg. to 212 deg. Fah. for about an hour. *Patent completed.*

1175. R. H. NICOLLS. *Improvements in taps or cocks for drawing off liquids.* Dated May 26, 1858.

To prevent and admit the discharge of the liquid through the tap, the inventor uses a valve or plug, which is *lifted up* out of the socket, by a cross lever fixed on a pin on the side of the tap, and applied to a stem which projects from the valve or plug. This lever is pressed down at one end by the hand being placed upon a key constructed for the purpose. *Patent abandoned.*

1176. J. LUIS. *An apparatus for baking fire-brick clay.* (A communication.) Dated May 26, 1858.

This patentee praises his apparatus, but forgets to describe it satisfactorily without reference to drawings. *Patent completed.*

1177. J. LUIS. *A distilling pipe.* (A communication.) Dated May 26, 1858.

This consists in replacing in the distilling and rectifying pipes the plates fitted up with the bells or knobs by a simple copper plate, pierced with holes, much in the same manner as a skimmer, the clearing pipe or pipes for the descent of the wine being retained as in the old plates. The jutting out of these pipes determining the height of the liquid must be in proportion to the thickness of the liquid; should it be very thick, the pipe must not jut out at all. *Patent completed.*

1178. J. LUIS. *An apparatus for cutting square-headed corks, and for corking bottles with the same.* (A communication.) Dated May 26, 1858.

This invention is not described apart from the inventor's drawings. *Patent completed.*

1179. J. LUIS. *The application and use of the fibrous textile plant, called in Arabia, "Diss," or in Latin, "Arundo festuca patula," or by botanists, "Festu coides et Donax tenuax," in the manufacturing of pulp for paper and tow for thread, tissues, and cordage.* (A communication.) Dated May 26, 1858.

The plants are sorted, cut by a machine into lengths of from 15 in. to 20 in. and placed in a boiler. They are there boiled for two hours in a mixture of soft water and American potash. They are then acted on by pestles moved by machinery, a current of fresh water being kept running over them. The matter thus obtained is carefully sorted, put in a bath of fresh water, taken out, dried, and stowed away ready for convenience. *Patent completed.*

1180. J. C. RIDDEL, D. RITCHIE, A. WATSON, J. F. ALLAN. *Improvements in cooking ranges, and other fire-places.* Dated May 26, 1858.

This embraces several details, including a flue space on top of the oven, provision for heating air, &c. The ranges are so formed as to need no setting. *Patent abandoned.*

1181. G. CHEADLE. *A new or improved flooring cramp.* Dated May 26, 1858.

This consists of a flooring cramp in which the mechanism for compressing the boards is actuated by a worm and worm wheel, the said worm wheel being situated upon the axis of the screw from which the compressing bolt or ram derives its motion. *Patent completed.*

1182. W. BAYLISS. *Iron tubular fencing to be used for general fencing as well as for the purpose of irrigation, and conveying water where required for agricultural or horticultural purposes.* Dated May 26, 1858.

This invention was described and illustrated at page 26 of No. 2, New Series. *Patent completed.*

1183. W. COWAN. *Improvements in machinery or apparatus for disengaging horses from carriages in cases of accident.* Dated May 26, 1858.

In one modification of apparatus there is fitted up, in the centre of the front of the vehicle, a vertical lever set upon a stud centre low down, and capable of a transverse vibratory traverse. This lever has at its lower end a segmental toothed rack in gear with a transverse horizontal rack formed upon the actual disengaging lever. Each end of the rack bar has an underneath elbow piece terminating in a small stud. These terminal studs fit into the double eyes formed upon the splinter and cross bars, taking the place of the joint studs for connecting the shafts to the bars for single harness work. And similarly for double harness

Digitized by Google

they fit into double eyes on the crossbar to which the splinter bar for the traces is attached by corresponding single eyes. To disengage the horse or horses, the driver works the actuating lever across from one side to the other, when the attaching studs are traversed out of their eyes, and the shafts or splinter-bar are released. To allow the pole in double harness to get free, provision is made for its attachment to the splinter-bar, so as to let both go together. *Patent abandoned.*

1184. P. A. FOURNASSIE. *An apparatus for clod-crushing, rolling, weeding, and scarifying, clearing, or preparing land.* (A communication.) Dated May 26, 1858.

This consists of a set of wheels or rollers with curved teeth, and combined with a set of arms or blades, so mounted as to be free to rise and fall and clear the earth, &c., thrown up by the teeth on the wheels. *Patent completed.*

1185. M. HENRY. *A new or improved fabric, and improved sewing and stitching machine, especially applicable for manufacturing the same.* (A communication.) Dated May 26, 1858.

Here the materials as they come from the carding engine are arranged in layers super-imposed to the desired thickness, and subjected to the action of needles (to which they are forcibly led by guide rollers), whereby the layers and also their component filaments are stitched together; the fabric is then fulled and finished off. The sewing and stitching machine is not intelligibly described apart from the drawings. *Patent completed.*

1186. S. C. SISTER and J. WARBURTON. *Improvements in spinning.* Dated May 26, 1858.

This consists in combing or heckling flax, &c., and then spinning it either wet or dry upon mules. Also in spinning flax, &c., upon cotton machinery, after being reduced to a state of flax cotton and then heckled or combed, or to a fibre, from half an inch to three inches in length. The patentees prefer to use galvanized iron rollers. Also in spinning the yarn soft, and then passing it through size or water. *Patent completed.*

1187. J. STUART. *An improvement in distilling asphalte, pitch, tar, and other bituminous substances.* Dated May 26 1858.

Here the asphalte, pitch, or tar, &c., is first ground, with lime or chalk, and then introduced into a still or retort, and products are distilled therefrom and condensed by condensing apparatus. *Patent completed.*

1188. F. BOUQUIE. *Improvements in the manufacture of chains.* Dated May 26, 1858.

Here each link is made out of two or more parts, each of which has received by the rolling process a form of such cross sections that one part may be introduced lengthwise and exactly fit into the other, so that when the overlapping sides of the various parts of each link have been brought together they will form joints of great solidity. *Patent completed.*

1189. A. C. ENGERT. *A method of preparing tinfoil or leaf, in order to its employment as a substitute for silver leaf.* (A communication.) Dated May 27, 1858.

This consists in mixing with the metal before being rolled out into leaf or foil, borax and nitrate of potass, or in coating the tin foil or leaf after being rolled with a solution of borax and nitrate of potass. *Patent abandoned.*

1190. J. SCHOLFIELD and G. HARLING. *Improvements in means or apparatus employed in weaving.* Dated May 27, 1858.

These relate to giving motion to shuttle boxes when a series is used, so that any one may be brought in position with the lay. The lever for lifting the series of boxes is connected to a lever or levers, formed with a series of segmental surfaces of varying depths, capable of being operated by rollers or pulleys, and adapted in number and depths to the distance of change of shuttle required. The patentees form the pulleys with bosses, to obtain capability of varying the changes by reversing these pulleys on their axes. *Patent completed.*

1191. C. CUIT and A. GODEFROY. *Improvements in railway breaks.* Dated May 27, 1858.

This relates to a brake having a frame with three sides, two of which are horn beams, between which the beams roll. To put on the break this frame is lowered on to the line of rolls thereon, on rollers, each having double spindles and a flange, and presents an incline to the wheel of the carriage, on which the latter wheel ascends. To remove the brake, the frame is raised between the wheels. *Patent abandoned.*

1192. W. CLARK. *Improvements in preserving butter.* (A communication.) Dated May 27, 1858.

The patentee beats up butter between two thicknesses of linen cloth, within seventy-two hours after it is made, to remove the whey, &c. He covers the butter with paper coated on each side with albumen made from the white of eggs, in which 15½ grains of chloride of sodium and half that quantity of salt of nitre is dissolved for the white of every egg. The paper is submitted to a hot iron. *Patent completed.*

1193. C. COWPER. *Improvements in machinery for combing and preparing wool, cotton, and other fibrous materials.* (A communication.) Dated May 27, 1858.

This relates to an invention patented by J. Heilmann, 25th Feb., 1846. In one of the machines comprised in this former patent the lap silver or fleece, &c., is broken asunder, and the fibres combed at each end, pincers being used to hold the material. Instead of giving the pincers a motion in a direction tangential to the combing drum, they move in a more radical direction, or to and from the centre of the drum, by which the motion of the lower bar of the pincers may be dispensed with. The upper bar may be moved by a crank, eccentric, or cam, the pressure being regulated by a spring. The feeding apparatus is made with a porcupine roller, which receives an intermittent motion from a disc and pin, and a star wheel, &c. A guide plate embracing some parts of the periphery of the porcupine roller serves to force the fibres into its pins. The detaching rollers are carried by levers mounted on an axis on the opposite side of the drum, or so placed as to admit of their moving to and fro from the pincers. These levers are worked by a cam or cams. *Patent completed.*

1194. G. H. BOVILL. *Improvements in the manufacture of fuel.* Dated May 27, 1858.

This consists in mixing with breeze or small coke, coal tar, melted pitch, &c. The materials are pressed into moulds to a density of 68 lb. per cubic foot. It also consists in a mode of carbonising fuel, so as to utilise the products evolved and prevent smoke. The blocks of fuel are placed in a closed chamber, heated to from 500 deg. to 700 deg. The volatile gases pass through a series of pipes in which a portion will condense from these condenser pipes; the uncondensed gases pass into heated retorts charged with coal, coke, charcoal, peat, &c., and are there mixed with the gas from the retorts,, converted into permanent gas, and pass into the gas-holders. The patentee blows into the ovens super-heated steam, to accelerate the process. *Patent completed.*

1195. V. S. VODOZ. *An improvement in the chimneys and glasses of gas and other lamps.* Dated May 27, 1858.

Here a disc of fine iron-wire gauze is raised at its edges, so as to produce a ring or frame suitable to fit on the upper part of a chimney or glass of a lamp. The flame is thereby improved, and smoke prevented. *Patent completed.*

1196. C. CLARKE. *Improvements in machinery for dibbling wheat and other grain or seeds and manure.* Dated May 27, 1858.

Here a series of dibbles are set round on the periphery of a wheel. Each dibble moves on an axis, so that, as it enters the land, it rotates on its axis. To deposit seed and manure in the holes, two apparatus are used in combination with the wheel, one of which contains the seed and the other the manure, and to each apparatus is applied a funnel having a valve at its lower end, which is opened and closed as the wheel is moved. The funnel of one apparatus supplies the seed or grain, and the funnel of the other the manure. *Patent completed.*

1197. J. BOWER. *Improvements in the manufacture of glass.* Dated May 27, 1858.

Here sulphate of barytes, reduced to powder, silica, or fine sand, and muriate of soda, are calcined at a strong red heat till they become a dry powder, consisting of silicate of barytes and sulphate of soda; this compound, with the addition of lime, is then converted into glass. When the glass is required free from colour the sulphate of barytes and sand are first purified with acid. *Patent abandoned.*

1198. S. OSLER. *The manufacture of fish into guano and food.* Dated May 28, 1858.

The patentee claims various methods of preparing fish for manure, by extracting the fluids and reducing the solid parts to a dry powder, by the prolonged application of heat. And preserving fish for food by separating in the same manner the fluid from the solid parts, and treating these solids with salt, saltpetre, sugar, &c., and with pepper, cayenne, or other spices. *Patent completed.*

1199. C. STANLEY and J. FITTALL. *Improvements in skylights and glass roofing.* Dated May 28, 1858.

This consists in giving the glass plates a trough-like figure, the plates being fixed on bars, &c., by clips engaging with the plates, the clips being fixed on the bars.—*Patent completed.*

1200. T. DUNN and W. IRLAM. *Improvements in machinery for altering the position of locomotive engines and carriages on railways.* Dated May, 28, 1858.

This relates, 1, to turn-tables, and consists in casting a flange at or near the lower edge of the ring of the turn-table top. 2, in making turn-tables of large dimensions with low string sides, or with tubular stays. 3, it relates to railway traversers, and consists in making the ends of the traverser rails of iron plates forming spring points, which points are depressed by the wheels of the carriage. 4, in making the ends of the traverse rails to swivel on fixed studs. 5, in placing the cross tram rails for the traversers on different levels. 6, in making a portion of the cross tram rails for the traverser capable of being raised and lowered by levers, screws, &c. *Patent completed.*

1201. M. A. F. MENNONS. *An improved key-joint for connecting detached pieces of wood or metal.* (A communication.) Dated May 28, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1202. M. A. F. MENNONS. *An aperient biscuit.* (A communication.) Dated May 28, 1858.

This biscuit contains the resin known as "Aleppo scammony." *Patent completed.*

1203. L. TINDALL. *Improvements in machinery or apparatus for sweeping and cleansing roads and streets.* Dated May 28, 1858.

This invention was described and illustrated at page 61 of our last number. *Patent completed.*

1204. J. F. LACKERSTEEN. *Improvements in machinery for cutting and splitting wood.* Dated May 28, 1858.

The pieces of wood are fed into a rectangular frame through which they are pressed at intervals the required distance. The ends of the frame are formed to admit a series of short cuttings to cut into the wood to a depth somewhat greater than that which is to be cut off at the next cut of one of the knives. *Patent completed.*

1205. A. GODET. *Improvements in raising weights.* Dated May 28, 1858.

When a windlass is employed, it is driven from a capstan by cog-wheels. By this means the windlass is driven by a continuous movement. *Patent abandoned.*

1206. A. ARNAL. *A nose-bag for horses.* Dated May 28, 1858.

This consists in forming the bag so that the corn is supplied to the horse in small quantities in place of the mass of corn being in contact with the horse's mouth. *Patent abandoned.*

1207. E. BOND. *An improved aerated liquid.* Dated May 28, 1858.

This consists of citrate of quinine and silicine dissolved in water with a little sulphuric acid. *Patent completed.*

1208. J. SHUTTLEWORTH. *Improvements in portable and other steam engine boilers.* Dated May 29, 1858.

In constructing the fire-boxes of steam boilers, the covering and side plates are made with flanges, which project upwards and outward, and to which the tube plate and front plate are fixed. The upper edges of the flanges of the covering plates and of the tube and front plates receive the ends of the stays which strengthen the covering plate. *Patent completed.*

1209. E., R. and P. SYKES. *Improvements in continuous spinning and roving machines for spinning and roving wool, a part of which is applicable to spinning other fibrous substances.* Dated May 28, 1858.

The patentee claims, 1, the contrivance of a drawing and retarding wing revolver. 2, a regulating and steadier blade. 3, an adjusting screw to raise or depress the regulating and steadier blade. 4, the arrangement and fixing of the tube box and the cap bar to the roller stands. The invention is not described apart from the drawings. *Patent completed.*

1210. W. and H. HODGSON. *Improvements in machinery, or apparatus for preparing and spinning or producing mottey yarns from rovings of unequal thickness of wool or other fibrous substances.* Dated May 29, 1858.

In place of only one pair of back rollers, the patentees use three rollers placed one over the other, and the smaller roving passes first over the top roller and betwixt the two uppermost, and then along with the other or thick roving between the second and third rollers, thus giving to the small roving an individual or independent nip. *Patent completed.*

1211. A. DOLD. *Improved apparatus for winding clocks, which apparatus is also applicable as a motor for all machinery usually turned by hand, horse, or other power, and for preventing the descent of smoke into chambers or other places.* Dated May 29, 1858.

On an upright hollow shaft, the upper end of which shall be in the open air, the inventor fixes a horizontal circular plate, above this a ring, and over the ring a dome; vertical bars or plates (working diagonally) pass from the circular horizontal plate to the ring supporting it. These plates are arranged to allow a greater or less quantity of air to pass through them to cut on fliers; a rod passes through the hollow shaft and circular plate; on the top portion of this, and between the plate and ring, certain volants or fliers are attached. The wind passes through the diagonal vertical plates impinged on the volants, and having turned the rod passes out; the rod thus rotating works into a gearing, and communicates motion thereto. *Patent abandoned.*

1212. S. ROCKEIT and J. J. REYNOLDS. *Improvements in the manufacture of umbrellas and parasols.* Dated May 29, 1858.

Owners of these umbrellas have only to remove a small portion thereof, and the umbrella becomes useless, until the said portion be replaced. *Patent completed.*

1213. J. MARTIN. *Improvements in means or apparatus for the prevention or cure of smoky chimneys.* Dated May 29, 1858.

The inventor forms, on the upper part of the stove, a moveable plate inclining upwards from front towards the back, and in the back of the stove applies a moveable plate extending inwards to within a short distance of the inclined plate, and so as to be overhung by it. This moveable plate has a passage behind it, and there is an opening from the passage thus formed to the apartment under the grate bars. He also forms the chimney pot with inclined plates projecting over, and at a distance from each other. *Patent abandoned.*

1214. T. V. LEE. *Improvements in the construction of steam generators, applicable to marine, locomotive, and all other uses where steam is applied as the motive power.* Dated May 29, 1858.

The inventor constructs the generator in two compartments, and through the under portion are a series of passages leading to a chamber in which a coil is placed. The heat and gases passing through the passages heat the coil, and is fully utilised before leaving the chamber by branch flues leading to the main flue or "take up," within the base of which is a chest to which the termination of the coil is connected; branches from this chest have suitable valves, cocks, &c. The steam generated in the under compartment is passed through the coil to the upper, which is fitted in the interior with suitable piping, a portion of which is perforated for the equal diffusion of the superheated steam or hydro-caloric throughout the water; suitable valves are placed on each compartment of the generator; steam for power is taken from a chest upon the upper portion, and when required a jet of hydro-caloric is taken direct to the cylinders of the engines from the chest within the "take up." *Patent abandoned.*

1215. M. A. F. MENNONS. *An improved fumigating apparatus.* (A communication.) Dated May 29, 1858.

This invention is based on an application of the reacting steam turbine principle to the construction of an apparatus for separating and distributing the volatile constituents of various perfumes and pharmaceutical products. *Patent completed.*

1216. D. HERSON. *Improvements in ships' gear, part of which is applicable to forming ropes for general purposes.* Dated May 29, 1858.

Here the masts, yards, &c., and the standing rigging are formed wholly or partly of steel, alone or in combination with wood. *Patent abandoned.*

1217. M. HENRY. *Improvements in, and in preparing agents for, dyeing, preparing for dyeing and tanning, and applying certain of the resulting products for obtaining pulp for paper and pasteboard, and the manufacture of blacking.* (A communication.) Dated May 29, 1858.

This relates to the treatment with acids or chlorine of vegetable agents for the above purposes. *Patent completed.*

DEATH OF DAVID TOD, ESQ.—We announce with regret the death of David Tod, Esq., of the eminent ship-building firm, Tod and M'Gregor, of Glasgow.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, FEBRUARY 4, 1859.

THE INCREASE OF THE NAVY.

"THE universal introduction of steam-power into naval warfare will render necessary a temporary increase of expenditure in providing for the reconstruction of the British navy; but I am persuaded that you will cheerfully vote whatever sums you will find to be requisite for an object of such vital importance as the maintenance of the maritime power of the country."—*Queen's Speech.*

THE gentlemen who discover in all taxes raised for naval and military purposes nothing but the cunning devices of a knavish aristocracy, should correct their opinion by what is now transpiring in reference to the navy. The Admiralty have determined to add considerably to the number of our line-of-battle ships; the First Lord of the Admiralty and the Surveyor of the Navy are early and late together, devising the necessary measures; the Chancellor of the Exchequer has coolly added a million or two sterling to his budget for the purpose; and the Navy Estimates will, in all probability, be passed with as great alacrity this year as last, and give equal satisfaction to the country, although the estimates of last year were cut down by the present Minister, and presented to the House as evidences of retrenchment. And yet there have been no aristocratical influences at work, in secretly bringing these things about. The speech of Lord HARDWICKE had, it is true, some slight influence upon the public mind; but it was an influence openly exerted, and in proportion as the statements of his lordship were erroneous—as they undoubtedly were in some respects—they failed in their design. The great and almost the only cause of the contemplated increase of the navy, and of the public approval of that increase, is to be found in the simple announcement of the fact that the French have more steam line-of-battle ships than ourselves. This announcement, which appeared originally in a leading article in the *Times*, and was subsequently confirmed in that journal by an authentic detailed statement from a correspondent, has alone determined the action of the Cabinet, and prepared the public to support them. Even the *Times* itself in no way urged either the Government or the country to pursue the course adopted, but was content to leave the former to act and the latter to think for themselves. When it is remembered that a single steam line-of-battle ship of the first class costs more than £200,000 sterling, and that the determination of the Admiralty therefore involves an extra expenditure of some millions, the all but unanimous approval of that determination by the country at large is the more remarkable.

But, however cheerfully an extra million or two may be granted for the navy, there will, we doubt not, be a strong and universal desire to see the money well spent. That it will be, in so far as the construction of efficient ships is concerned, there is but little ground for doubt. But as an extra half-a-million will probably be expended in the ensuing year in the dockyards on workmen's wages, for the building of the new ships, it will be necessary to consider how this may best be applied. It may be expended, first, by entering extra men in the dockyards; or, secondly, by placing the established workmen upon unlimited earnings, and allowing them to work extra hours; or, thirdly, by both of these methods combined. In our judgment—and we speak from close observation in the matter—the second method is the best. We feel perfectly confident that the work of a Government dockyard can never be well and economically done by any but men who are accustomed to it. Shipwrights brought up in private yards always require some months of training to it before they can perform it with either efficiency or quickness. This is true of the best of them. But, unfortunately, it is generally the worst of them only who are willing to accept temporary employment in Her Majesty's dockyards; and such men of course require much longer training. Besides these considerations, there is the further one that the Government workmen consider it a benefit to be allowed to work extra hours, and to earn wages limited only by the scale of prices under which they work while on day-time, and their desire in the matter should be studied. The entry of new and often worthless men whenever extra money is to be earned, is painful to the established servants of the Government, and exerts a demoralising influence upon them. The Admiralty should study the wishes of their servants in this respect to the fullest extent possible without detriment to the service. As an election may not be far off, and as the dockyard men can return their favourite in several boroughs, the political instincts of the Government will doubtless co-operate with their desire to do justice in the case. The dockyard servants of Her Majesty may therefore expect to work very hard, and to earn very large wages for the next year or two.

DEFECTIVE LINE-OF-BATTLE SHIPS.

A CORRESPONDENT signing himself "An Old Salt," sends us the following letter on a subject which well deserves the attention of the Admiralty, and to which we therefore give a prominent place:—

"Having lately read in your periodical the very able paper of Mr. REED, on the previous and present states of naval architecture in this country, as well as several other articles relating to the navies of England, France, and United States, I am led to draw your attention to a matter of vital importance connected with our steam-fleet, hoping thereby to do good. All ship-builders and naval officers seem now to be perfectly cognisant of the necessity of having ships for war purposes built upon lines which shall produce the steadiest platforms in a seaway for fighting their guns upon, in order to secure *rapidity* and precision of fire. Unfortunately for the navy of this country, it possesses at the present moment a larger number of converted Symondite line-of-battle ships whose previous formidable evil of rolling quick and deep has been, in most instances, much increased by placing steam machinery in them. The following is, I believe, a correct list of these vessels:—*Princess Royal, Hannibal, Algiers, Exmouth, Colossus, Majestic, Centurion, Brunswick, Goliath*, all auxiliary power of 450 and 400-horse power. The lines of the two first on the list were considerably altered while on the stocks, which has improved them, and partially overcome the evil tendency of the late Surveyor's ships; but the latter have merely been altered by the stern, which has in no measure corrected the peg-top form below water, and their tendency to roll deep and quickly has been aggravated by the position of the weights of the machinery and boilers. The officers and men who have had experience in these ships will be able to vouch for the correctness of the following statements. *Exmouth* on her first trip to sea rolled away her main yard, and ran great risk of losing her masts in consequence of the violence of her motion. She has since frequently flung the shot out of her racks on her decks, and obliged her crew when on watch to lie down on the decks, and sustain themselves by the bolts, &c., to prevent their being hurled to leeward by the violence of the rolls. *Colossus, Brunswick*, &c., are equally bad in a seaway, even in moderate weather making it dangerous to cast loose the guns for the ordinary exercise of the hands, while ships in company have not hesitated to do so. Now, in the event of a Channel fleet being formed in the ensuing spring, some of these ships will, in all probability, form portion of it; and if the authorities require yet to be convinced, an opportunity will be given of testing the truth of my statement by desiring the commander of the fleet to exercise the ships at general quarters *under steam alone*, placing the Symondites in one line and the remainder in another, and then, placing himself in a favourable position for observation, decide which line ought to win an action. Only conceive the position of one of these ships in hostile collision with one of the new ships of the French steam navy, rolling 30° each way in a moderate seaway—and this is not overdrawn, for this has been a common occurrence, even when with sail set, which had a tendency to steady them—at every alternate roll exposing a space halfway down from her waterlines to her keel to the guns of the enemy. What would be the result after a couple of broadsides? In all probability she would go to the bottom with her gallant crew before the action was half over. It is to try for a remedy for this monstrous evil in these war-ships, that I am induced to address you, in order that the matter may come to the notice of the authorities, so that, by the aid of bilge-pieces, or by doubling below the waterline, and so altering their lines, they may steady themselves when in action under steam, and so give officers and men fair play in the event of another naval conflict. Dry rot used to have a great affection for the Symondite ships a few years back; what a comfort it would be if it would lay hold severely of some of these wonderful vessels, and so bring them to the end of their days quickly."

The defects of our Symondite line-of-battle ships are in no degree exaggerated, we believe, in the preceding letter, while the number of such ships is understated. To the list of vessels given by our correspondent may be added the *Duke of Wellington, Royal Sovereign, Windsor Castle, Aboukir, Mars*, and *Meanee*, which have been but slightly altered from the lines of Sir WILLIAM SYMONDS. All these, with others now undergoing conversion into screw ships, are open to the serious objections so ably stated by the writer. The application of bilge-pieces, as suggested by him, would doubtless do much to remedy the defects of their form. Such pieces were applied to some of the gunboats built during the late war, and were found to reduce both the time and the extent of their rolling motions *one-half*. This fact, apart from others of like tendency, is sufficient to render an experiment upon one of the larger vessels highly desirable, and we hope to see it made without unnecessary delay. It will be far more pleasant to find that the letter of "An Old Salt" has led to the cure of a dozen costly line-of-battle ships, than to learn that the dry rot has devoured them. To prevent error, we may state that the *Algiers* is of 600-horse power, and not of 450, as our correspondent implies.

PATENT-LAW REFORM.

How many a good cause has suffered from bad patronage! No greater evil can befal a popular movement than that of winning the favour of fools or hypocrites. Who would subscribe to the Field Lane Refuge should URIAH HEEP become the president? Who would attend the special services at St. Paul's, were CHADBAND

Digitized by Google

to preach the sermons—who go to hear Mr. GOUGH's oration with STIGGINS in the chair—who vote for Mr. BRIGHT's Reform Bill were PECKSNIFF to move its adoption? And yet who ever knew of a reform movement of any kind that was not beset by a class of persons eager to turn it, by means more or less specious, to their own account, although by so doing they alienated all respectable persons from it?

Ever since the passing of the Patent Law Amendment Act of 1852, there has existed a certain party—and "party," be it remembered, is as often singular as plural—labouring to beget as much dissatisfaction as possible with that Act, and by doing so to gain a little prominence. At one time, we believe, an Association with a very imposing title was formed expressly to bring about an amendment of that amended Act. This Association comprised one member, who had the honour of founding it, and who unanimously elected a council, consisting of himself, and then, having the casting vote, appointed himself successively Chairman, Secretary, and Treasurer—by ballot we presume. When the advertisements of the "Great Universal Cosmopolitan Patent Law Reform Association" appeared, there was found in them a paragraph to the effect that one of the promotors of the Association, who had long advocated Patent-Law Reform, would be very much obliged to anyone who would entrust him with the obtainment of their patents for them, at very moderate charges. It is exceedingly probable that his plea obtained him a client or two, who we trust were ably and faithly served! The plan was doubtless as ingenious as it was patriotic; and as everyone is at liberty to imitate it, be he needy or prosperous, Jew or Gentile, knave or saint, it will probably meet with many imitators. The fundamental idea involved in it is susceptible of numerous developments which will occur to clever fellows who are above the prejudices that keep most men from entering upon professions of which they know nothing.

But by those who are at all intimately acquainted with the working of the present Patent Law, and are cognisant of the views entertained by statesmen respecting it, nine-tenths of all that has been said and written about Patent-Law Reform since 1852 has been properly set down as the injurious babbling of needy men. Well-informed persons knew well that the Houses of Parliament would never force the Government to change a law which was most carefully considered before it was enacted, until the operation of the law had been tried for a moderate period, and the real evils connected with it carefully pointed out. They have, therefore, viewed with disgust the senseless clamour which a few self-seeking individuals have kept up, and have felt that the cause of true reform was suffering from the conduct of these people.

But the Act has now been in operation more than six years, and during the present year a fee of £100 will have to be paid upon patents obtained in 1852, or the existing privilges of the patentees will expire. The time has now come, therefore, when it is essential that a serious re-consideration of the Act should take place, and we observe with pleasure that Mr. FAIRBAIRN and others are moving in the matter. On Friday last a meeting was held at the Town Hall, Manchester, to petition Parliament "to allow the surplus fund arising from the stamp duties on patents to be appropriated to scientific purposes; and for other amendments in the existing laws." Mr. W. FAIRBAIRN presided, and, after announcing the friendliness of the members for Manchester to the movement, said that some time ago it cost £500 to take out a patent; but this sum was reduced in 1852 to about £175. Notwithstanding this reduction, a considerable surplus in the funds of the Patent-office remained every year, and it had gone on increasing yearly, until it amounted last year to £94,167. It had been stated, he continued, that the Chancellor of the Exchequer had no objection to apply this surplus to scientific purposes. A large amount would probably be required for building new Patent-offices, but if, after that, the Government were willing to apply the remaining funds to scientific purposes, and also to reduce the charges of taking out patents, he thought it would be better to allow the Government to make the change spontaneously, than to force them to do so by adopting petitions at special meetings. The inventor was already taxed for all the necessaries of life, and it was too much, he thought, to tax his genius also. After these judicious remarks by Mr. FAIRBAIRN, a petition to Parliament was read and adopted. The nature of this petition we shall discuss next week.

THE PRESERVATION OF STONE BUILDINGS.

FOR some time past, the preservation from decay of absorbent building-stones exposed to the humid atmosphere of our climate—loaded as it often is with acid vapours—has been attempted with more or less apparent success, and has become at length a subject of national importance. We have only to remind our readers of the condition of much of the exterior of the new palace at Westminster which was built of a selected magnesian limestone, and of almost all the buildings erected within the present century of Bath or Caen stone, to justify this remark.

It is well known that most building-stones are composed of grains of limestone or sand, cemented together by some material—generally carbonate of lime—and that such stones will dissolve rapidly in carbonic or very dilute sulphuric acid, or will even be destroyed by moisture alone, when assisted by the frequent contraction and expansion resulting from changes of temperature. By the rotting away of the cementing medium, the grains, though often unaltered in composition, become disconnected, and fall away from each other, sometimes in flakes, sometimes in powder. This is called *disintegration*, and may be observed in almost every limestone building in London. It is prevented for a time, by coating the stone with paint; but paint, consisting of white lead mixed with oil, is itself decomposed by exposure to damp air, and undergoes actual decay, after which it ceases altogether to resist disintegration.

It does not seem possible that any preparation containing animal or vegetable matter, subject to decomposition, can act on stone as a permanent preservative; so that to great public buildings, where neither disfigurement nor a constant repetition of external applications is admissible, all such inventions, however promising in other respects, are inapplicable. We have carefully looked over the specifications of the various patents taken out for the last ten years on this subject, and of these (seventeen in number) we find in no less than eleven the presence of oil, glue, resin, gum, blood, vinegar, or other decomposing animal or vegetable substance. While some of these inventions may be of great value for sheltered and internal work, we cannot but observe that they must all fail as permanent defences against the action of the atmosphere in London and other large towns. This seems to us a chemical necessity—for not one of these substances, no matter how mixed up with other materials, can fail to become oxidised, and ultimately decomposed, if exposed to external atmospheric influences. It is certain that when any one part of a composition, laid as a coating on an absorbed surface to which it can adhere only partially, becomes decomposed and destroyed, the film or coating cannot retain even its original capacity for resisting absorption.

Recognising the importance of avoiding substances that admit of oxidation, five of the inventors whose patents are before us employ silicates or aluminates of soda and potash to wash the stone, expecting to obtain, after evaporation, a mineral film on the surface, or within the surface, which they believe will be found insoluble and non-absorbent. Many trials on a large scale have been made with similar preparations in France, and have been favourably reported on; but it is only too evident that the deposit of a film on the surface of a decomposing stone, however insoluble the film may be, or however perfectly it may for a time seem to answer, must ultimately fail. No such film can be deposited in any other than a porous state, and any decomposition that may have already commenced at the time of its application will go on, and soon throw off the deposited surface, and wherever any moisture has penetrated, the inevitable contraction and expansion must soon produce the same result. There is in this process no adhesion secured to the less decomposing grains of the stone, so that the tendency is for the weak places in the stone to lose their defence the first.

There remains only one of the seventeen patents to be alluded to; but this one proposes to effect its object by a *double decomposition*, and by an actual re-construction of the surface of the stone, replacing the soluble and easily-injured cementing medium by one which is insoluble and indestructible. It is not difficult to explain how this is effected, as the method involved is familiar to all in its practical results. Everyone knows the extraordinary durability of old mortars and cements, and of our hydraulic cements, but the cause is not so well known. In the use of these cements, grains of sand, or of pebbles or other stones, are fastened together by a thin glazing of silicate of lime, deposited on each surface during the setting, owing to the decomposition of part of the silicate of alumina which the cement contains, and the extreme readiness with which lime enters into combination with silica under favourable circumstances. Under the patent in question, the patentee, Mr. FREDERICK RANSOME, of Ipswich, proposes to coat the stone to be preserved with a solution of silicate of soda or potash in water, which he prepares under steam pressure in large quantities in the manufacture of his admirable artificial stone. After this solution is absorbed, it is followed by a second wash, consisting of chloride of calcium. A double decomposition immediately takes place within the substance of the stone; the chlorine, combining with the soda, producing common salt, is washed away during the first rains, and the calcium, combining with the silicic acid, forms a tough insoluble silicate of lime, attaching itself firmly round the surface of each separate grain of the stone, and forming an extremely compact deposit, not acted on either by carbonic or dilute sulphuric acid, and identical with the material which holds together the separate grains or stones in hydraulic cements and concretes.

This ingenious method of re-composing the outer and decaying surface of stone seems to us to offer every prospect of ultimate success; and, as far as experience goes, it is satisfactory to find that when applied between two and three years ago on some of the worst portions of the river front of the new palace at Westminster, the decay that had commenced was absolutely stopped, and the rotten surface is now so hard, that the point of a sharp knife cannot detach the smallest fragment, or disclose any tendency to scaling. This cannot be said of other parts

Digitized by Google

treated by different processes, where the destruction, checked for a time, is now advancing as rapidly as ever.

For the information of our readers, we have given on another page a list of the principal inventions which have recently been patented in this country bearing upon the subject.

ON THE PRODUCTION OF ILLUMINATING GAS.

Of all the great manufacturing processes—in which the smallest improvements affecting the result, and visible as an increase in the net profits, is often of the greatest moment in a commercial point of view—probably the most imperfect at the present time is the first and principal operation in the production of coal-gas. It needs very little chemical knowledge to be aware that the products of the destructive distillation of coal may be made to vary almost *ad infinitum*, according to many modifications of the conditions which determine the decomposition. The proportion between the essential constituents of coal-gas, as obtained by the usual process of manufacture, (olefiant gas and light carburetted hydrogen,) and of its most important impurities, (carbonic acid, sulphuretted hydrogen, ammonia, cyanogen compounds, and bisulphide of carbon) ranges within broad limits, and is found to differ in almost every operation. Nevertheless, little attention appears hitherto to have been paid to the study of the conditions under which the decomposition of the coal takes place; and few attempts have been made to bring the scrutiny of science to bear upon the chemical changes which occur within the gas retort. The only important improvement of which we are aware relating to the production of illuminating gas, is that of allowing a jet of steam to pass through the retort; by which means valuable gaseous products, which otherwise would undergo decomposition, are carried off as quickly as they are evolved. A portion of the steam is also decomposed and hydrogen gas produced, together with carbonic oxide. The jet of steam affords, or should afford, a ready means of regulating the temperature of the retort.

Although this process conduces in great measure to the two most important results to be attained in the manufacture of illuminating gas, viz., an increase in the proportion of olefiant gas or heavy carburetted hydrogen, and the substitution of pure hydrogen for a portion of the light carburetted hydrogen, still, it is far from satisfying every requirement. The production of carbonic oxide gas in considerable proportion is in itself a serious objection. In some recent experiments, presently to be alluded to, the carbonic oxide produced is made to promote a chemical action of considerable importance in the newly-discovered process which is adopted, and becomes converted into carbonic acid—readily removed in the purifying apparatus by means of milk of lime.

In considering the action which takes place within the retort, with reference to the low conducting power for heat of the coal, it is evident that while one class of products is being produced from the fuel in close proximity to the heated surface of the retort, another class is evolved from the central portion of the mass. It cannot be doubted that great waste and uncertainty is the result of this unequal distribution of heat. When the central mass has gained the degree of temperature at which the most valuable products are evolved, the surrounding temperature has become sufficiently high to decompose these products. Thus the central portion is first exposed to a heat insufficient for the production of coal-gas, but which volatilizes the most valuable constituents of the coal; and towards the conclusion of the process, the olefiant gas evolved is converted into light carburetted hydrogen, or pure hydrogen and carbon, which is deposited on the sides of the retort as the hard crust known by the name of gas-carbon. The following table is given by HENRY of the gaseous products of the distillation of coal, at various periods of the operation; and it shows that towards the termination the gas evolved must deteriorate by dilution with a large amount of products possessed of little or no illuminating power:—

Time of collection.	In 100 parts of Gas from Wigan Cannel Coal.				
	Absorbed by Chlorine.	Light Carburetted Hydrogen.	Carbonic Oxide.	Hydrogen.	Nitrogen.
In 1st hour.	13	82·5	3·2	0	1·3
	12	73	1·9	8·8	5·3
	12	58	12 3	16	1·7
5 hours after commencement.	7	56	11	21·3	4·7
10 hours after.	0	20	10	60	10

Two remedies suggest themselves to obviate the unequal distribution of heat throughout the coal. The first, presenting many practical difficulties, is to diminish the proportion of the volume of the retorts to their extent of surface; and the second, the possibility of which appears to be confirmed by experiment, is to increase artificially the conducting power for heat of the mass within the retort.

A series of experiments, from which we anticipate valuable results, has been undertaken by Mr. DESMOND G. FITZGERALD, in conjunction with Mr. A. C. KEILY, with a view to the economic production of illuminating gas of superior quality. The process to which these experiments have led, involves several chemical reactions, and the application of catalytic action, combined in an operation sufficiently simple to admit of its adoption beyond the precincts of the laboratory. It will probably before long be described in our columns.

THE WATT MONUMENTAL TOWER.—The ground is being prepared for the reception of the monumental tower which it has been proposed to raise to the memory of Watt, and which will be reared in the Cemetery occupying the heights to the west of the town of Greenock, the birthplace of the great mechanician. Some of the Italian Campanili have been used as types. The testimonial is to be placed on an elevation, so that the top of the tower will be 514 feet above the level of the sea. The upper turret is adapted for the reception of an electric time ball, and for nautical and astronomical observations. Internally the structure will comprise rooms of about thirty feet square, connected by means of a circular staircase and open gallery, and having on their sides a series of niches and recesses suitable for the reception of statues, busts, or other memorials commemorative of men eminent in science or philosophy. In the erection of this testimonial, it is intended to incorporate gifts of materials from every quarter of the globe. Contributions of the most interesting and varied character have already been received from Bombay, Malta, and many places on the shores of the Mediterranean; from various parts of England, Scotland, and Ireland; from Sebastopol, Maryland, Italy, Isle of Man, and from many other parts. A mass of material is promised, including lime and stone sufficient to build the first fourteen feet. An object of this vast character is of necessity slow in progress, but it is hoped that twelve or fourteen years may possibly complete it.

SCIENTIFIC PROGRESS IN AUSTRALIA.

THE day on which the intercolonial telegraph was first opened to the public of New South Wales, Victoria, and South Australia, was the 29th of October; and we are now enabled to throw a little light on the causes which so long delayed the work. It seems that the first contractor in the New South Wales division was unable to carry out his undertaking. His tender was very low, and the Government hesitated as to its acceptance, but apparently satisfactory sureties having been offered, it was not considered advisable to reject the offer, which was the lowest sent in. But the result showed that a mistake had been committed. Time rolled on, and the cheap contractor made so little progress with his work that although there was every disposition to show him reasonable indulgence, it became necessary to cancel the contract, and make arrangements with some other party. The second contractor, from unavoidable circumstances, did not complete his undertaking within the stipulated period; but the work was well performed, and the delay was caused by the difficulties of the soil, the want of suitable timber in some districts, and disputes on the part of the workmen. Another point of interest in connection with this matter has reference to the gutta percha covering of submarine telegraphs, which is found to have received injury in consequence of being stowed away in the hot holds of ships. It is understood that some submarine cable sent to India was rendered useless from this cause; and in South Australia—where the summer heat is very great—the cable submerged in Lake Alexandrina was exposed for some days to a temperature of 100 degrees, and the injury sustained is reported to have been so serious that the work is to be done over again. The cable, it is stated, is to be taken up, and wires are to be carried over the Murray river near its mouth, on posts of a sufficient height to allow the free passage of vessels below. This is a subject well worthy the consideration of all engaged in submarine telegraphy in hot climates like those of India and Australia.

As regards the future, there is some talk of a submarine cable between Victoria and New Zealand. This would be a serious affair, involving an expenditure of nearly £200,000, and as there are at present only 50,000 or 60,000 Europeans scattered over the six settlements of New Zealand—each having, after the approved Australasian fashion, a little legislature—the undertaking seems rather premature at present. It remains to be seen, however, what course events will take. In New South Wales, extensions from the main line just completed are to be proceeded with in the direction of the rising towns of Bathurst and Maitland, the requisite funds being provided by a public loan. This course has been adopted with regard to the New South Wales portion of the intercolonial line, but in South Australia and Victoria the expense has been defrayed out of the current revenue. The recent rush to the supposed new goldfield near Port Curtis has proved a failure; but while the district has not been found all at once to be auriferous, although eminent authorities still believe that it is, there is little difference of opinion as to its beauty and fertility, so that a few years will witness it the home of a population content to forego the feverish pursuits of the gold-digger, and to obtain a livelihood by steady industry. If this should prove to be the case, and it is only a question of time, a further extension of telegraphic communication will be needed in this direction, which, it is contended, will afford the best route for communication with Asia and Europe. Reference to the map will show that this is a likely view of the case, as an enormous length of wire would have to be carried from Adelaide to Swan River, and from Swan River to some point in the neighbourhood of Cambridge Gulf, if operations were determined on on the other side of the continent, while a greater length of submarine cable would be required between Cambridge Gulf and Timor than between Cape York and New Guinea.

The Austrian frigate *Novara*, which is present

Digitized by Google

ing a scientific voyage round the world, was at Sydney at the date of the last advices. Port Jackson now affords great facilities for repairs, and the *Novara* has been dismantled and placed in the government dry dock.

The last advices from New South Wales note the commencement of a small portion—only a very few miles—of a railway dignified with the high-sounding title of Great Western. The course which the system is to take has, however, not yet been decided on. Railway works seem to progress but slowly in this colony; and well they may, for, as they are carried on exclusively by Government, and the principle acted on is that they shall be extended equally in all directions, the result is a few bit-by-bit extensions, leading at present to mere geographical points. The Great Southern Railway, which is carried from Sydney as far as Campbelltown, a distance of 34 miles, is taking nearly 30*l.* per mile per week; and, therefore, there seems every reason to hope for a fair return on the capital expended. The aim of the Great Western Railway is Bathurst, and the point at present undecided is where the line shall strike the river Nepean.

The greatest interest seems to have been taken in Australia in the submersion of the Atlantic telegraph, the temporary success of which was the topic of the day at the date of the last advices (the middle of November). Indeed, if one were interrogated as to the salient idea occupying the colonial mind, the answer would probably be, "Telegraphs," which seem to stand before railways. The fact is, the Australians have been so long shut out of the European world that any probability of overcoming the fearful distance which separates them from their commercial and personal friends is eagerly welcomed. One member of one of the Legislatures positively expressed an opinion that it was scarcely worth while to enter into an expensive contract for improving steam communication with England in the face of the Atlantic telegraph being an accomplished fact, which could be soon repeated in the Pacific. By this time, these too hasty anticipations have been probably set at rest.

There is a good deal of chronic grumbling in England with reference to the rates paid for gas; but what would the grumblers say to the rates current in Australia for this important article? An Australian Gas Light Company was first formed in 1836, and lighting operations were commenced at Sydney in 1841. The original capital was £25,000, and as the Company's operations have extended, this has been gradually increased to £81,000. Dividends ranging from 7 to 10 per cent. per annum have been declared, besides five bonuses (one 10 per cent.), in fifteen years; but this return must not be considered an extraordinary one, as at Melbourne another company, established for similar purposes, has received as much as 12 per cent, and some of the banks and commercial associations of the place have divided from 10 to 20 per cent. A bill has recently passed the New South Wales Legislature authorising the Sydney Company to further increase their capital to £300,000. The entire extent of the Sydney Company's mains is now reported to be about 42 miles, and the charge made is 15s. per 1,000 cubic feet; at Melbourne it is still higher, 25s. per 1,000 cubic feet, and the same price remains in the Tasmanian capital. These enormous rates are justified on the ground that every article employed in the manufacture of gas costs in Australia three times as much as in England. Some complaints have been made of the quality of the Sydney gas, but this is attributed to the inadequacy of the company's machinery to produce an article of the requisite purity to meet the largely-increased demand. This difficulty is, however, being provided against. There are 300 public lamps in Sydney, but these are situated a considerable distance apart, and the lighters have to traverse 84 miles of street every day. The Company's principal engineer is Mr. Barlow. It employs 120 men, while three ships are regularly employed in bringing coal from Newcastle—a port to the north of Sydney.

The New South Wales Government has lately placed a steam-dredge on the Hunter river, which disembogues in the sea at the harbour of Newcastle. The Hunter, which was formerly termed the "coal river," is formed by several streams flowing from the Blue Mountains, and has been navigable 50 miles from Newcastle by small craft of 30 to 40 tons. Beyond this distance there are several shallows. The river has three branches—the upper, lower, and middle—and the two former are navigable for boats for 120 miles, while the latter can be ascended 200 miles. All the branches are subject to sudden floods from the rapid of waters from the Blue Mountains. The steam-dredge is designed to remove as far as possible the impediments to navigation on the Hunter, and also to improve the port of Newcastle. The dredging portion of the machinery has been constructed by Messrs. Russell and Co., of Sydney; and the dredge has been designed by Mr. Moriarty, Government Engineer. The length between perpendiculars is 105 feet; length of keel for tonnage, 84 feet 9 inches; extreme breadth, 30 feet; breadth for tonnage, 29 feet 10 inches; burden, new measurement, 230 tons. There are two sets of ladders and buckets, one on each side with 29 buckets on each frame. The engine is of the ordinary side-lever description; diameter of cylinder, 30 inches; and length of stroke, 36 inches. The screw-propeller makes 100 revolutions per minute, and is 5 feet diameter, and 8 feet pitch. The dredge is shifted in position while at work by the engine.

NORMANDY'S PATENT MARINE FRESH WATER APPARATUS.

In order to explain more fully the principles upon which the apparatus described in our last number has been designed, we condense the following remarks from a paper by Dr. Normandy now before us. He writes as follows:—

"At first sight, one would think that it is sufficient to submit sea water to distillation to convert it into fresh water, and that the solution of the problem is altogether dependent upon a still, constructed so as to produce, by evaporation, a great quantity of distilled water, with a consumption of fuel sufficiently small to become practicable. Distillation, at a cheap rate, is doubtless an important item; but there are besides other desiderata of a no less primary importance, and it is from having neglected, ignored, or been unable to realise them, that all the apparatuses for transforming sea water into fresh water, which have, from time to time, been brought before the public, have hitherto proved failures, or fulfil the object in view in a very imperfect or precarious manner. When water, whether salt or fresh, is submitted to distillation, the condensed steam, instead of yielding a pure, tasteless, and odourless liquid, has *always* an almost intolerably nauseous, empyreumatic taste and odour, which it retains for many weeks. This taste and odour are so disagreeable, and the water so produced being, as is the case with ordinary distilled water, deprived of air by boiling, is, on that account, so heavy, indigestible, and vapid, that the crews invariably refuse it as long as they can obtain a supply from natural sources, even though this may be of so bad a quality as to endanger their health or their lives. To remedy these defects, chemical re-agents, such as alum, sulphuric acid, muriatic acid, chlorine, chloride of lime, &c, to be added to the distilled water, have been proposed; but it is evident that the continuous and daily absorption of chemical re-agents might, and doubtless would, cause accidents of a more or less serious nature, not to speak of the trouble and care required in making such additions, an excess of which might be attended with dangerous, and possibly with fatal consequences; besides, as a general rule, we have the authority of Liebig to say, that the use of chemicals should never be recommended for culinary purposes, for chemicals are seldom met with in commerce in a state of purity, and are frequently contaminated by poisonous substances. On the other hand, the pumps, ventilators bellows, agitators, the percolation through porous substances, through plaster, chalk, sand, &c., which have been proposed to aërate the water obtained, and render it palatable, are of a difficult, inconvenient, or impossible application; they are costly, complicated, bulky, or unmanageable. Another desideratum lost sight of in the endeavours which have been made to accomplish the object (and it is a condition of extreme importance) is to obviate or prevent the deposit of saline matter which takes place in the apparatus when the limit of saturation has been attained, and which, in a short time after use, interferes temporarily at least, often permanently, with the working of the apparatus, renders frequent repairs necessary, and in all cases eventually destroys it. The expansion of metals by heat and their contraction by cold, is another source of failure; so much so, that it can be most truly asserted, without fear of contradiction, that any fresh-water distilling apparatus for marine purposes, in any part of which solder is employed, is, *ipso facto*, defective, and ought not to be trusted, and this perhaps (as the event has unfortunately more than once proved) at a time when the machine was most wanted, its unsoundness thus creating the most distressing sufferings, and putting the lives of all on board in imminent jeopardy. The question, which has hitherto been left unanswered, and yet which must be integrally solved before success could be hoped for, is the following:—To obtain, with a small proportion of fuel, large quantities of fresh, inodorous, salubrious, aërated water, without the help of machinery or of chemical re-agents, by means of a small and compact apparatus, incapable of becoming incrusted, or otherwise going out of order. It is to the solution of this difficult and complex problem that I now beg to call attention, and I will proceed to explain the construction of the apparatus by which the object is attained. It is known that natural waters are saturated with air containing a larger proportion of oxygen and of carbonic acid than exists in the air we breathe. Whilst ordinary rain water contains, on an average, about 15 cubic inches of oxygenised air per gallon (of which about 6 are carbonic acid), sea water contains only, on an average, about 5 cubic inches (of which about 0·6 or 0·7 are carbonic acid). or, in other words, one gallon of sea water contains about two-thirds less air than ordinary rain or river water. I have also ascertained that air begins to be expelled from such waters when the temperature reached about 130° Fahr. Now, my apparatus consists of two parts—an evaporator and a condenser—joined so as to form one compact and solid mass, screwed and bolted, without solderings or brazings of any kind. The evaporator consists of a space which is pervaded by steam-pipes containing steam, and immersed in a certain quantity of sea water, a portion of which is to be evaporated; steam, at a pressure of about seven pounds, is then admitted into the steam pipes of the evaporator, which steam-pipes are constantly surrounded by the sea water to be operated upon, and which thus becomes heated by them. The steam is procured on board of steamers directly from their boilers, and, consequently, at a trifling cost: in sailing-ships it is obtained from a small boiler, which may or may not be connected with the hearth, galley, or caboose. The steam of the above-mentioned pressure being of course hotter than ordinary boiling water, serves to convert a portion of the water contained in the evaporator into ordinary or *low-pressure* steam, which, as it reaches the condenser, is resolved therein into fresh water. By thus evaporating water under a slight pressure, one fire performs double duty, and thus the first condition, that of economy, is completely fulfilled, for whilst, in the usual way, 1 lb. of coal evaporates 8 or 9 lbs. of water, the same quantity of coals is thus made to evaporate 16 or 18 lbs. of water. With an apparatus constructed on the principle which was sent to Copiapo, in Chili, 30,000 gallons of fresh water per diem are obtained from the sea. The steam issuing from the evaporator, and which is condensed by the water in the condenser,

Digitized by Google

imparts, of course, its heat to the sea water in it, and as this water is admitted cold at the bottom, whilst the steam of the evaporator is admitted at the top of the condenser, the water therein becomes hotter and hotter gradually as it ascends, and when it finally reaches the top, its temperature is about 208° Fahr. I have already stated that water begins to part with its air at a temperature of about 130° Fahr., therefore, the greater portion of the air contained in the water which flows constantly and uninterruptedly through the condenser is thus separated, and led through a pipe into the empty space left for steam room within the evaporator, when it mixes with the steam. Now, as about six gallons of sea water must be discharged for every gallon of fresh water which is condensed, it follows that the steam in the evaporator, before it is finally condensed, has been in contact with twice as much air as water can take up, the result being a production of fresh water to the maximum of aëration, that is, containing as much air as in pure rain water, whilst, the upper part of the condenser being open to the atmosphere, all pressure is thus removed from the apparatus. This aëration of the water is a condition of the utmost importance, and, in fact, is a condition which, were it not accomplished, would render the apparatus comparatively useless, even though the other desiderata were fulfilled. The only condition necessary for distilled water not to become putrid or offensive is to saturate it with *pure air*, because in that case there is no room left for other gases to impregnate it, at least, practically speaking, and in the ordinary conditions of domestic or of ship economy. Dr. Stenhouse, several years ago, I believe, found that the power which charcoal possesses of purifying tainted air is owing to its burning in an insensible manner the substances to which its bad odour was due; and acting upon that discovery of Dr. Stenhouse, I found that charcoal has the power of destroying the empyreuma of distilled water *when such water is* AËRATED, that is to say, when it contains atmospheric air, or oxygen. I found by experiments, carried on upon a somewhat extensive scale for many months, that two cubic feet of charcoal are sufficient to remove entirely the empyreumatic odour and taste of distilled water, produced at the rate of 500 gallons per diem, and that the charcoal *never wants renewing*, because it does not act as a filter, but as a burner, the substance burnt being the empyreumatic product, and the result of the slow combustion thereof being carbonic acid and water. I have every reason to believe, from the length of time during which several of my apparatus have been in operation, that such a filter once made will last for ever, because the charcoal disinfects the water, so to speak, as it does air, not by mechanical separation, but by actual though insensible combustion. The water, as it issues from the apparatus, is perfectly sweet, tasteless, inodorous, and completely saturated with a maximum quantity of pure air; it is of sparkling clearness, and being refrigerated in traversing the coiled pipe surrounded by the cold sea water at the lower part of the apparatus, it is fit for immediate use. And thus is the second condition, that of aëration, of digestibility, of wholesomeness accomplished, whereby the water so produced is *at once* drinkable, and so sweet and fresh that it cannot be distinguished from the very best spring water."

EXHIBITION OF INVENTIONS.—The Society of Arts' eleventh annual Exhibition of Inventions will open on the 25th day of April, 1859. The days fixed for receiving articles intended for exhibition are, Thursday the 7th, Friday the 8th, and Saturday the 9th of April. No charge is made for space; the Exhibition is free.

IMPROVED POCKET-BOOKS AND PORTE-MONNAIES.—Messrs. Schloss, of Cannon-street, City, have applied their well-known piston lock to pocket-books, &c. For this especial purpose it seems admirably adapted, and the effect gives a good deal of additional elegance to the new porte-monnaies now so fashionable.

INSTITUTION OF MECHANICAL ENGINEERS.

THE twelfth annual general meeting of this Institution was held on Wednesday, the 26th ult., at the Institution, Newhall-street, Birmingham, John Penn, Esq., president, in the chair.

The Secretary (Mr. W. P. Marshall) having read the minutes of the previous meeting, the annual report of the Council was then read, which showed the satisfactory position of the Institution, and a large increase in the number of members, referring also to the highly successful special meeting held in Newcastle-on-Tyne last summer. The election of officers for the present year then took place, John Penn, Esq., being re-elected President of the Institution. A number of new members were also elected.

A paper was then read "On the Progressive applications of Machinery to Mining Purposes," by Mr. Thos. John Taylor, of Easdon, Newcastle-on-Tyne, giving an account of the several processes and mechanical appliances employed in the Newcastle coal-field from the earliest times, with the various improvements gradually effected, and the progressive applications of machinery introduced into the different branches of coal mining in that district. A simple construction of direct-acting engine was described as being introduced in place of the large beam engines. The points to be kept in view in attempting the substitution of mechanical means for furnace ventilation were also stated. They are, that the same quantity of air should be supplied, and that the supply should be equally constant and certain, and attended with greater economy. The progress and gradual development of railways in the colliery districts was referred to; and the great need at the present time of improvements in the underground arrangements for conveyance of the coal was urged, the cost of conveyance underground being three or four times that above ground. A notice was also given of the rapid advances in coal mining already realised by the development and extended application of the powers of the steam engine. The paper was illustrated by an extensive and interesting series of diagrams.

The next paper, by Mr. Benjamin Fothergill, of Manchester, was a "Description of a Dry-Clay Brick-making Machine." The machine (which we shall probably describe hereafter, when the drawings are before us) is constructed by Messrs. Platt, of Oldham, and one has been at work there for some time; an important economy is stated to be effected in the course of manufacture, as well as superior finish obtained in the bricks produced. Specimens of the bricks made by the machine, burnt and unburnt, were exhibited with samples of the clay from the several stages of the process; also a working model of the brick press.

The meeting then terminated, and in the evening a number of the members dined together at the Hen and Chickens Hotel, in celebration of the twelfth anniversary of the Institution.

MANUFACTURE OF STEEL TINPLATES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

Gentlemen,—In their anxiety to inform the public of the facts relating to this branch of manufacture, the Mersey Iron and Steel Company have verified the adage of "the more haste the worse speed." Tinplates had never been made from puddled steel before Mr. Spence made them, and so far from the cast steel tinplates which were previously manufactured, having been made from steel manufactured in the ordinary way, they were actually made from cast steel, manufactured in a very extraordinary manner; and as the cost of this manufacture does not exceed £8 per ton, I presume it was not the high price of the cast steel in question which rendered the matter abortive. If Mr. Muntz was legally and equitably entitled to a patent for applying the known metal copper and the known metal zinc to the well-known purpose of making brass, then it follows that Mr. Spence is as clearly entitled to a patent for applying the known metal tin and the known form of iron called "puddled steel," to the known purpose of manufacturing tinplates, and if Lord Campbell can upset this deduction, he will succeed in establishing a dangerous precedent.

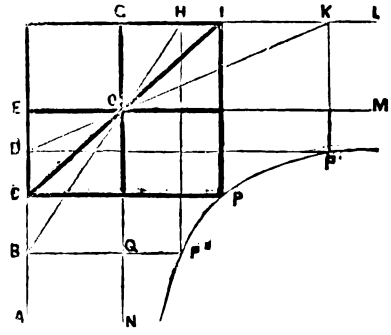
Of the novelty of manufacturing puddled steel tinplates, no unprejudiced person can for a moment entertain a doubt, and the improvement effected is so manifest, that in equity (not, perhaps, legal equity) no impartial judge could refuse to confirm the patent. ROBT. MUSHET.

Coleford, 25th January, 1859.

HYPERBOLIC CONSTRUCTION FOR ESTIMATING THE EXPANSION OF STEAM.

MR. J. SIMON HOLLAND, of Woolwich, sends us the following, on a method of constructing an expansion diagram:—

In your last volume, page 373, you gave a method of constructing rectangular hyperbolas, which appears to have been invented by Mr. Thurnell, and described by him to the British Association, Section A, 1858. I beg to forward a method I invented some time ago, applicable to all hyperbolas, no matter what may be the angle formed by their asymptotes. I have found it useful on several occasions. To find a number of points it is only necessary to have a parallel ruler.



By Euclid 43, the rectangle OP = rectangle FO, being the complements about the diagonal CI. Next if we take the diagonal DK, FO and OP' will be equal. And so with the diagonal BH, $FO = OP''$. Now if we draw a curve through the points $P'PP''$ that curve will be a hyperbola, and the lines OM, ON will be its asymptotes. To find other points, draw oblique lines through the point O, and then from where they cut the lines AF, FL draw lines parallel to AF, FL, and where they intersect we have a point in the curve. All rectangles drawn between the hyperbola and its asymptotes are equal to each other. The rectangles OP, OP', OP'', are each equal to the rectangle FO, and therefore to each other.

The curve eternally approaches its asymptotes, yet never touches them. The diagonal BH never can become parallel to GN, therefore the point P can never touch the line GN. Neither can the point P' touch the line EM, because DK can never can become parallel to that line.

To use this method in making a curve to show the expansion of a steam engine according to Boyle's law, make EA the stroke of the piston, according to any scale, and make EF, on that scale, equal to the part traversed by the piston before expansion. Make GI the scale of lbs. pressure, G being zero, and I the pressure at which steam is cut off. Then $P''Q$ or GH will show its pressure when the piston has arrived at B. A line drawn through the point O from any part of the stroke scale, will pass through the lbs. scale and cut it at a point showing the corresponding pressure. The locus of the point P will be the curve required. J. SIMON HOLLAND.

Woolwich, Jan. 17, 1859.

CHEAP BOOKS.—The committee of the Society for the Diffusion of Pure Literature, have granted to the Council of the Society of Arts the privilege of giving recommendations to the Institutions in Union, enabling them to obtain at half-price libraries of £5 worth and upwards of books, to be selected from a catalogue issued by the Society, and which will be supplied to any Institutions applying for it. The principal objects of the Society are to promote the circulation of such books, periodicals, prints, diagrams, and other publications as the committee may, from time to time, deem really useful and good, whether they are issued by individuals or by Societies. Institutions desiring to avail themselves of this privilege, should communicate with the Secretary of the Society of Arts,

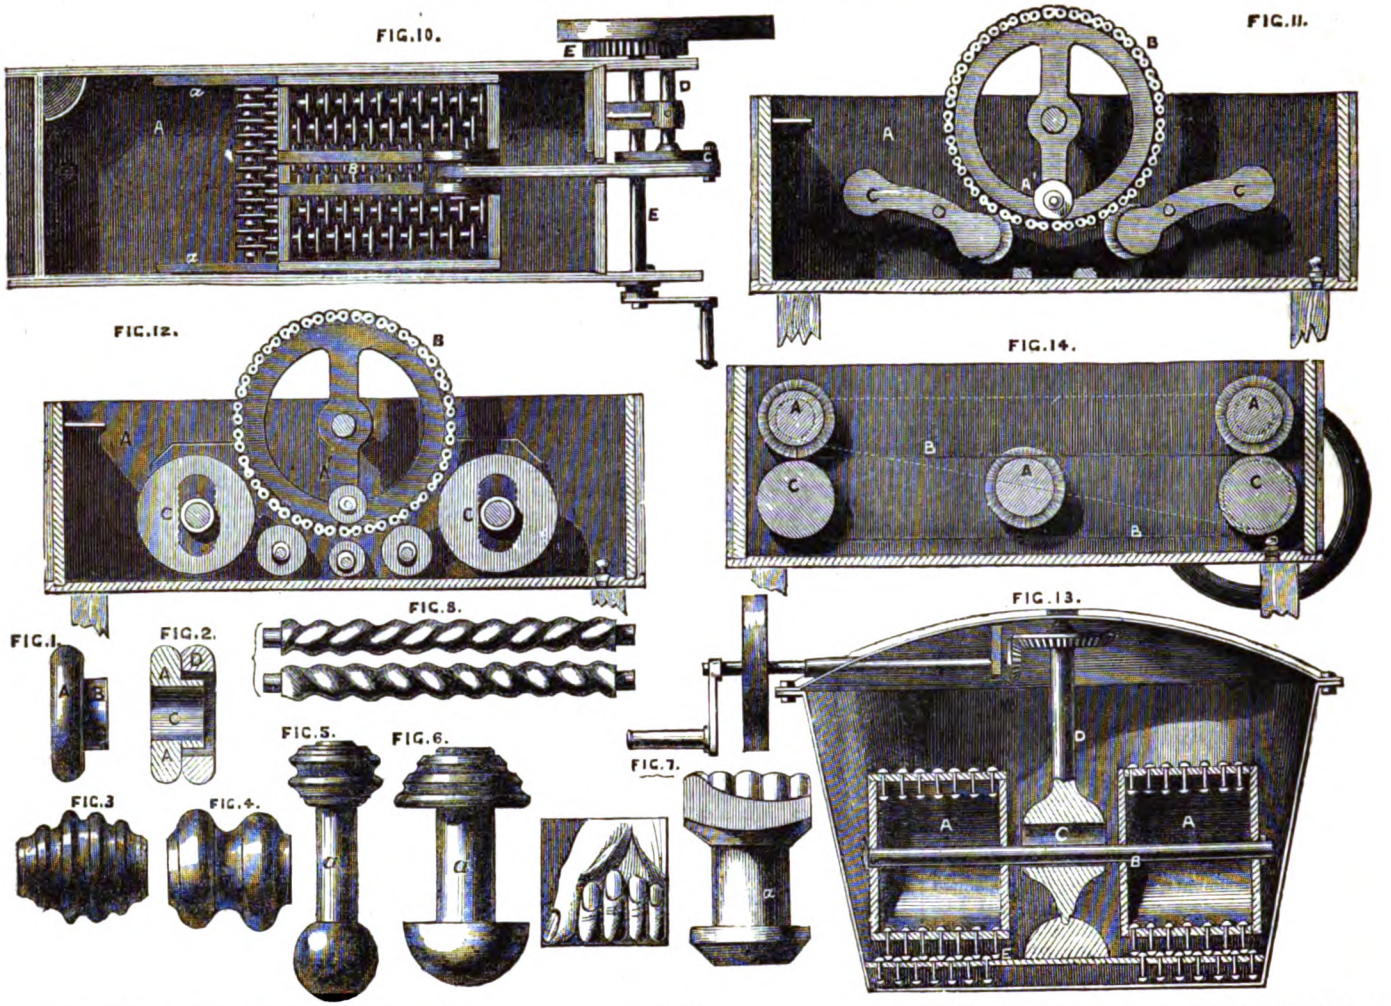
WHEELER'S PATENT WASHING MACHINES.



WHEELER'S PATENT WASHING MACHINES.

AMONG the numerous devices lately brought forward with the view of superseding the arduous labour of washing by hand, a set of machines very recently patented by Mr. Thomas Wheeler, of Oxford, merit especial notice. Considering, apparently, that hand washing, however wearing it may have been, was much more efficient than the washing of many of the apparatuses by which it has been replaced, Mr. Wheeler has endeavoured to imitate by machinery the action of the hand in the operation. The annexed engravings illustrate the principal features of this invention:—

Figs. 1 to 9 inclusive represent detail views of the variously-shaped rubbers which he proposes to adopt in his several washing machines. These rubbers may be composed of wood or other buoyant material; and, in the case of the rubbers shown at Fig. 9, stamped metal may be employed. Fig. 1 is a side and edge view of what is called a "shouldered rubber." It consists simply of a disc, *A*, having a shoulder, *B*, turned upon one or both sides of it. A round, square, oblong, or triangular opening is made through the centre of the rubber for enabling a series of them to be mounted in a frame or holder, as shown in the plan view of a reciprocating washing machine, Fig. 10. Fig. 2 is the shouldered rubber combined with a ring rubber, *D*, the shoulder being made to enter and play freely within the opening of the ring rubber. Fig. 3 is a corrugated rotary rubber, consisting of a cone or cylinder, having corrugations, undulations, or projecting rings formed upon its surface with a central aperture; and fig. 4 is another corrugated rubber having both its projecting rings or corrugations of the same diameter. All these four different rubbers are to be used in the same manner. They may be fitted into frames for receiving a reciprocating motion, as shown at Fig. 10; or they may be fitted into cylinders to receive a rotary or partial rotary motion, or carried on pegs or pins for working in inclined slots, or applied in the form of endless bands by being threaded on cords in any convenient manner to form aprons of rubber. Figs. 5, 6, and 7 are shank rubbers intended to be used either in the reciprocating frames or in rotary cylinders, as shown in the latter case at Fig. 11, the shanks, *a*, fitting into suitable holes in the frame or cylinder to allow of the rubbers

FIG. 9.

floating or working freely therein. These rubbers are formed with a head, *b*, at each end, one or both heads being corrugated or turned into concentric rings, as in Figs. 5 and 6, or formed with other hollows and projections thereon, as in Fig. 7, which represents the form of the human knuckles in the act of washing. Cork or other buoyant materials may be added; or they may be made hollow to increase their buoyancy. The whole of the rubbers assimilate in their action to that of the knuckles of the hand, and therefore are termed knuckle-rubbers. Fig. 8 represents two of a series of spiral rubbers to be arranged side by side in a reciprocating frame; and Fig. 9 is a reciprocating rubber composed of a number of imitation knuckles formed of stamped metal, or of wood, gutta percha, or other suitable substance, and secured to a flat board, or to a cylindrical or curved surface. Fig. 10 represents a plan of a reciprocating washing machine, fitted with the "shouldered rubber," Fig. 1. This machine consists of an oblong box or tank, *A*, fitted at the bottom of the tank with a number of shouldered rubbers, or with any of the forms of floating rubbers before referred to. When the revolving rubbers are employed, that is, any of those illustrated at figs. 1, 2, 3 and 4, they are threaded upon wooden or metal spindles, which are placed side by side in suitable holes in the side pieces, *a*, *a*, fixed into the tank, *A*, the holes being sufficiently large, or of such a shape, as to allow the spindle to float and play freely therein, whilst the holes in the rubbers are also made large enough to allow the rubbers themselves to float and play freely upon the spindles. The reciprocating frame, *B*, is similarly furnished with a set of floating rubbers. These rubbers are arranged at right angles or otherwise to the rubbers beneath them in the tank. The frame is worked to and fro by a connecting rod and a crank or eccentric, *C*, on the second motion shaft, *D*, which receives a quick motion from a spur wheel, *E*, or by a driving band on the first motion shaft, which may be driven by hand or by a small engine attached to the side of the tank, the escape steam from which may be passed into the tank, and employed for heating or keeping hot the water therein; the bottom set of rubbers may, in some cases, be made reciprocating or rotating as well as the upper one. Any of the rubbers may be fitted into frames and used in the machine, Fig. 10. Another rubber consists simply of a brush, and another is merely a combination of the rubbers shown at Fig. 2. Fig. 11 represents a washing machine composed of a tank, *A*, a rotatory cylinder, *B*, and a number of floating rubbers in the form of levers, *C*, *C*, fitted with brushes at their extremities, and bearing against the surface of the cylinder, to which cylinder the clothes, flax, wool, or other materials to be washed are attached by means of loops or bands. In the machine, Fig. 12, the levers are replaced by circular floating rubbers, *C*, *C*, constructed after one of the methods before described. Fig. 13 represents a rotatory washing machine composed of a pair of hollow cylinders, *A*, *A*, revolving on a spindle, *B*, passed through a slot, *C*, in the vertical shaft, *D*, which is driven in any convenient manner. The cylinders may be fitted on this surface with any of the rubbers. We have represented the corrugated rubbers (Figs. 5 and 6) as being applied thereto, and working in conjunction with similar, or with any of the other rubbers in a frame or species of false bottom, *E*. The spindle and cylinders are free to rise or fall in the slot, *C*, according to the varying thickness of the clothes or other substances between the two sets of rubbers. The patentee is aware that rollers revolving in a tub or vessel have been previously employed in washing machines, and therefore claims only the application of hollow cylinders, fitted either internally or externally, or on both surfaces, with any of the improved rubbers. When the patentee uses cylinders, as in the machinery shown in Figs. 11 and 12, he proposes to wash smaller or lighter articles by placing them inside such cylinders, and submitting them to the action of rubbers strung together as shown at *A'*, Figs. 11 and 12, or otherwise placed loosely therein. By these machines three different sets of clothes or goods may be washed simultaneously. Thus, some articles may be attached to the tapes or loops on the outer surface of the cylinder; others

Digitized by Google

contained inside the same, and a third set laid upon the floating or other rubbers at the bottom of the tank. A series of any of the rubbers shown at Figs. 1, 2, 3, and 4, may be connected by cords in the form of an endless band of rubbers, and placed on the surface of the cylinder to be used in combination with other rubbers in the tank or washing vessel. Fig. 14 represents a washing machine composed of circular brushes, *A*, *A*, acting in combination with an endless travelling net, *B*, of open or large mesh, and combined or not with rubbers as before referred to. This net is carried on rollers, *C*, *C*, and has the articles to be washed attached thereto in any convenient manner, whilst the brushes, *A*, will act through the net so as to cleanse or rub both sides of the linen simultaneously. In place of rotatory brushes a reciprocating rubber in combination with the open net may be employed, and fitted either with benches or with any of the other rubbers.

ON A QUICK-WORKING POWER-ENGINE.

ABOUT two years since, an English Baronet addressed us a manuscript bearing the above title, requesting that it might be printed in our columns. Believing it unsound, we refused the communication, and were at some pains to satisfy the author, who had spent much time and energy upon the invention, that he was incorrect in some of his views. After much further study and research, the author has again addressed us upon the subject in the following note, which was accompanied by the paper in a revised form. As his request is a moderate, and, all things considered, a very natural one, we have consented to comply with it. Should any of our readers feel disposed to offer any observations upon the author's paper, it will be convenient for them to defer doing so until the publication of the document itself is completed :—

GENTLEMEN,—The enclosed paper, the subject of which is "A Quick-working Power-Engine, by a Variety of the Application of the Natural Principle of the Hydraulic Press," is divided into four sections, under the heads of—the principle, the plan, the working and management, and the motive power; and I beg the favour of you to publish these parts severally in successive numbers of your Magazine.

Every attempt of this kind by a mechanical method was sure to fail, because what could be gained in time must be lost in power. The method now proposed is dynamical, with no reliance on mechanical gain for either speed or power. The principle is founded on the law that what is called the hydrostatic paradox can be realised only in a vessel which is both full of water and close, excepting where it is open to admit of pressure from without on the contents.

I enclose my card, and have only to add that I shall most willingly give explanations asked for by any of your correspondents, if you will be so good as to answer applications for my name and address. Your obedient servant,

Dec., 1858. G. B.

ON A QUICK-WORKING POWER-ENGINE, BY A VARIETY IN THE APPLICATION OF THE NATURAL PRINCIPLE OF THE HYDRAULIC PRESS.

The Principle.

It was long ago conceived by reason and proved by experiment that a peculiar and gratuitous power may be derived, with some appliance of force by art, from confined water; and at a later time, the discovery was turned to account in the invention of the hydraulic press. Water, confined in a pipe a small section of one inch in diameter, and pressing from a high level on the liquid contents of a close and full barrel, may cause it to burst as if the volume pressing were of the diameter of the barrel itself. This is accounted for by the incompressibility of water by less than thirty thousand atmospheres, and by its faculty of pressing with equal force in all directions; so that a very small extent or amount of pressure from without may cause an equal degree of pressure within to the extent of all the inner surfaces of a close and full vessel. And thus, if a piston forms a part of the inclosure, it is pressed on the whole of its exposed surface, however large, by a multiplication of the amount of pressure from a thread of water, which may be injected easily against a very great degree of resistance, because the amount of resistance is small, as is the volume of the water forced in.

But, in the same proportion, the quantity supplied is small to fill up the space through which the large piston is moved; and the consequence is slowness. The quantity is very small, and the movement very slow, because the injection proceeds from a piston as small as the thread of water, and further, because the injection, which is by pressure against a valve that shuts itself between the strokes of the pump, is intermittent. Another imperfection is, that the working must be discontinued to get back the large piston, by letting out the water. Slowness, and the necessity for suspending the work, may be scarcely inconveniences for many purposes; but if the natural and gratuitous power intrinsic, as is above explained, to the hydraulic press, could be employed to give rapid and continuous action, the improvement would be of incalculable value, and really wonderful. The common hydraulic press is wonderful. The most eminent proof of how much more it returns than it receives in amount—a property belonging to it alone of all engines or machines—was displayed in lifting the tubes of the Britannia Bridge at the Menai Straits, by a twenty-horse steam engine forcing a small finger's breadth of water against a tight-fitted piston, twenty inches in diameter, and loaded with that enormous weight.

Then for the supply to the reservoir to be copious enough to give quick motion, it would be necessary that the forcing piston should be large; which would not prevent the volume that entered being very small, if the discharge were contracted in a finely-tapering pipe But, for the forcing piston to be large, it would be necessary to prevent a reaction taking place against it on the principle of the hydraulic paradox above described.

Now, closeness as well as fullness everywhere is indispensable to the operation of that principle. The object, therefore, would be obtained by leaving the passage between the forcing piston and the reservoir open at one place. With an hydraulic press, the passage is closed throughout; and, therefore, if the piston that forces were as large as the other, the degree of reactionary resistance to the injection would be multiplied in amount against it according to the extent of its surface, and no advantage could be gained. But it would not be so if the pipe conveying the discharge were divided by a narrow aperture, to be closed and opened by a sliding valve, and through which the water should be driven down upon the contents of a tapering perpendicular part of the pipe beneath. The tapering, as it accelerated the motion, would at once ensure plentiful supply and a great intensity of pressure; nor could any increase of resistance from it be communicated to the forcing piston on the principle of the paradox if the opening were between, and such increase would be a very slight drawback on the benefit from the reduction of volume and the intensifying of force.

(To be continued.)

ALLAN'S ATLANTIC CABLE.

ON Wednesday, the 26th, Mr. Thos Allan, C.E., of London, addressed a numerous meeting of merchants in the Underwriter's Room, in this town, in explanation of his system of submarine telegraphy. Mr. William Brown, M.P., presided. Mr. Allan exhibited a specimen of his patented light cable. The core or conductor is composed of solid copper wire, surrounded with steel wires, covered with two coatings of gutta percha, and an outer one of a mixture partly made from gutta percha, but having the toughness of leather. The lost Atlantic was a type of the heavy cables, and his of the light ones; and although his was less strong than the other, it was for the purposes required probably four or five times stronger, because, from its lightness, it could be so easily payed out, and would sustain seven miles of itself hanging vertically from the ship, if it were possible that could occur. As to strength, it was not so much the breaking point as that at which the cable stretched that had to be considered. When the gutta percha was stretched, insulation was impaired, and that must affect the working of the cable; and a spiral wire must yield under a strain. Instead of sinking 2,000 fathoms in 20 minutes, this cable would take two hours; but of course it would sink, as it was heavier than water. This increased the facility of paying out, which might be done at the rate of eight or ten miles an hour. As compared with the lost cable, this had 120 per cent. more conductibility and about double the insulation. He would go direct from this country to Halifax; and he thought Liverpool ought to be the starting point. The route had not been sounded yet, but it would be desirable that it should be. Mr. Allan said he was promised that the American Congress would vote a subsidy equal to that voted to the last cable, if his was landed on American soil, and he had been in close communication with our Government; and he referred to the confidence with which his plan was submitted so far back as 1853, and to the influential and scientific support it had received, and still possessed. A conversation followed, in which questions were asked by the Chairman, Mr. Bushell, Mr. Heath, Mr. Mondel, and others, and the plan was further elucidated in the answers given by Mr. Allan. Mr. Allan's statement and explanations were listened to with great attention and interest, and some gentlemen expressed their decided preference for Mr. Allan's system as compared with others.—*Liverpool Paper.*

STEAMERS WANTED FOR INDIA.

THE Calcutta correspondent of the *Times* writes as follows :—

"Is there no enterprise left among the shipbuilders of England? We hear month after month that steamers are coming and coming, but they do not come; and the India General Steam Navigation Company declares this month a dividend of 100 and upwards per cent. Nobody at home seems able to comprehend that there is a traffic on the Ganges such as has never been seen there since the days of the Hindoo sages. Even the Home Government do not understand it. They were indented on the other day for six river steamers. They sent one, which they said would be sufficient. Next month the Indian Government had to engage all the freight of six for two trips at a price which would have bought the new vessels they wanted twice over. I saw a professional estimate the other day which proved that there was room and work for 300 steamers on the Ganges alone. Nor is the figure wonderful if you will recall the number on the Mississippi, and remember that if the Ganges is smaller, it flows through a territory with a population of 350 to the square mile, an export trade of £16,000,000, and an internal trade which no man can measure."

THE IRON TRADE OF THE NORTH.

THE Iron trade of the North is in a tolerably satisfactory condition—70 furnaces, out of 87, being in blast. The following statement on the subject will be found interesting :

Locality.	Furnaces in blast.	Out of blast.
Eston	12	0
Middlesborough	8	0
Wilton Park	4	0
Cargo Fleet	5	2
Port Clarence	5	0
Felling	2	0
Wylam	0	1
Washington	2	0
Stockton	3	0
Norton	2	1
Darlington	2	1
Stanhope	0	1
Tow Law	5	0
Consett	16	2
Lemington	1	1
Birtley	2	1
Walker	3	1
Wallsend	0	2
Jarrow	3	1
Bedlington	0	2

Other furnaces will be shortly in operation.

MESSRS. W. G. ARMSTRONG AND Co. of Elswick, near Newcastle-on-Tyne, have decided on extending their gun-factory to the extent of 130 feet beyond the original plans, and have given orders for the immediate execution of the work.—*North of England Advertiser.*

TAYLOR'S PATENT HORSE-HOES AND DRILLS.

FIG. 1.

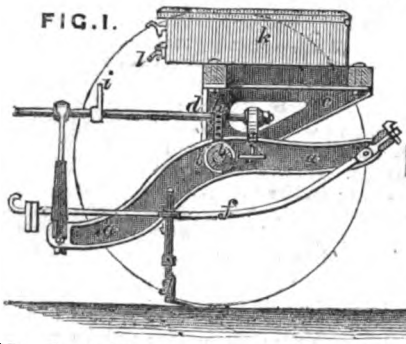

FIG. 2.

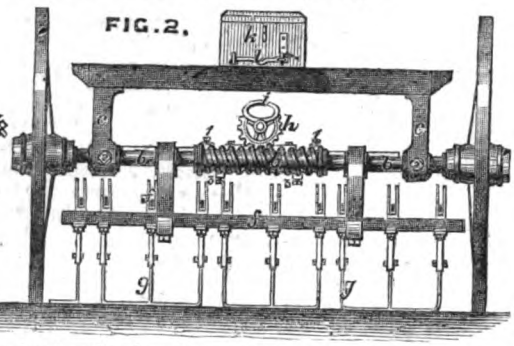
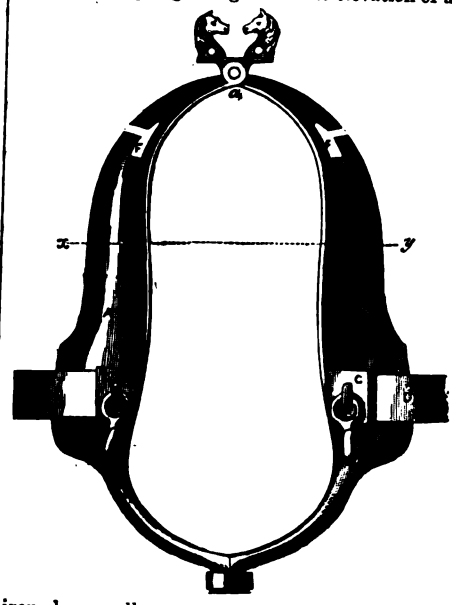


MR. JOHN TAYLOR, farm bailiff, of Swanton Novers, Thetford, Norfolk, has patented "an improvement in horse-hoes, applicable also as drills," which deserves the notice of agriculturalists. The chief object of this invention is to simplify the construction of horse-hoes, and to give to the attendant more complete command than heretofore over the implement when in work, so that while guiding the hoes he may instantly throw them up out of action, and thus avoid the liability common to horse-hoes, of even the most approved construction, of their swaying about and cutting up the crop during the time requisite for lifting the hoes free of the ground. These advantages are attained by mounting the hoes on independent levers, which are severally jointed to the forward end of a balance frame, which is both capable of rocking and sliding upon its fulcrum, and can, therefore, be moved both vertically and horizontally by the same guiding shaft or lever.

In the accompanying engravings, Fig. 1 is a vertical section of a horse-hoe, constructed according to this invention; Fig. 2 is an end elevation showing the gearing for giving the lateral motion to the balance frame. *a*, *a*, is the balance frame, which has for its fulcrum the axle of the carrying wheels. This axle is composed of three parts, viz., the shafts *b*, *b*, and the coupling tube *b'*, and is thus made capable of expansion and contraction to facilitate the adjustment of the wheels breadthwise to the work. This axle carries also the draught frame *c* of the implement. The balance frame *a*, it will be understood, is mounted loosely on the axle *b*, and it receives its motions from a steering rod or lever *d*, which turns in bearings provided for it on the frame. To the forward end of the balance frame, the slotted bar *e* is secured for receiving the levers *f*, which carry the hoes *g*. On the inner or forward end of the steering rod *d* is keyed a segment rack *h*, which gears into a worm rack cast on the tubular coupling *b'* of the axle, and the outer end of the rod is fitted with a hand wheel or handle for the attendant to grasp while the implement is in use. When a lateral motion is required to be given to the hoes to get them into the proper position for working, it will not only be necessary to turn the steering rod in its bearings to the right or left as the case may be, and the whole of the hoes will by reason of the segment rack gearing into the fixed worm rack be shogged in the required direction, and to the amount requisite to bring the several pairs of hoes into the proper position relatively to the rows of growing crop. In order to lift the hoes clear of the ground, or for the purpose of changing the angle of inclination of the cutting edge of the hoes, the guide rod is pressed upwards by the attendant, when, acting as a lever, it will raise the hoes, the movement being facilitated by the counterweight of the portion of the frame which lies on the forward side of the axle *b*, or centre of the rocking motion. Instead of the segment and the straight rack, other gearing, as a pulley and chain, or their equivalent, may be employed for imparting the lateral motion to the balance frame. To facilitate the lateral adjustment of the carrying wheels, the patentee casts the coupling tube *b'* with an internal worm, and fit on the ends of the shafts *b*, *b*, a pin or pins for taking into the worm. In the normal state of the compound axle, the several parts will be held firmly together by the binding screws 1, 1, but when he requires to expand or contract the axle he slackens these binding screws, and also the binding screws 2, which fix the draught frame *c* to the axle, and turns the implement round on one or other of the wheels, the effect of which movement will be to rotate the shafts *b* in the coupling tube to the right or left hand according to the direction of the movement given to the implement, and thus expand or contract the axle to any required amount; 3, 3, are retaining screws for keeping the shafts *b*, *b*, within the coupling tube. To keep the hoes free of the ground when the implement is travelling over roads or to its work, a metal loop *i* is fixed to the steering rod, and the hind end of the tool box *k* is fitted with a hook to receive the loop. A hasp *l* (Fig. 2), also attached to the box, may be used to prevent the loop being jerked off the hook, the hasp being brought under the elevated steering rod, and secured in position by a pin or wedge. The above-described arrangement of balance frame applies also to drills, and serves to facilitate the adjustment of the coulters while those implements are in operation. The mode of applying the improvement to this class of implements will be obvious to any practical mechanic, and therefore no special description will be needed.

IMPROVED HORSE COLLARS.

MR. CHARLES LAMBERT, farmer, of Sunk Island, East Riding of York, has obtained a patent for improved collars for horses and other draught animals, which embody some desirable changes in the manufacture of these articles. His invention consists in forming collars of iron, wood, or other hard substance in two halves or parts, united at top by a hinged joint, and secured at bottom by a thumb-screw passed through two projecting pieces, one from each half of the collar, or by other equivalent means. Tug pins or eyes are formed in a piece with, or are attached to the sides of the collar. The traces are connected to these pins or eyes. The improved collar forms at once a collar and harness; and by shaping the inside of the two side-pieces in conformity with the shoulder of the animal for which the collar is intended little or no padding is required. The accompanying engraving is a front elevation of an



iron horse-collar constructed according to this invention. The collar is formed in two parts, *A* and *B*, united at top by a hinge joint *a*, and fastened at bottom by a collar *b*. The position of the parts of the collar, when placing it on or removing it from the animal, is indicated by the dotted lines. The sides of the collar are adapted to the shoulders of the animal. *C C* are eyes or sockets on both sides of the collar, which the inventor prefers to cast with the collar, and to place at right angles, or nearly so, thereto. In these sockets he fixes the tug hooks *D D*, held by screws or springs. *E E* are hooks attached to the sockets *C C*. *F F* are holes in the collar to pass the reins through. We have seen specimens of the improved collars, and think very highly of them.

HART'S PATENT ECONOMIZING GAS-BURNER.

A GAS-BURNER lately patented by Mr. Hart, and exhibited for some months past on the patentee's premises in Fleet-street, near to our own office, has attracted so much attention, and appears to be selling to so large an extent, that, were it a much less useful article than it is, we should be disposed to gratify public curiosity respecting it. As it is really a very valuable little contrivance—capable of simultaneously economizing the gas, improving the light, and preserving the eyes of those who work or write by gas-light from serious injury—we notice it with pleasure. It does not differ very much in construction from inventions which have previously been brought before the public, but, from all that we can observe and learn, it is more efficient, and less liable to injury of every kind than any burner before produced. That its nature, which is very simple, may be fully understood, we have had the accompanying representations of it engraved.

FIG. 1. FIG. 2.

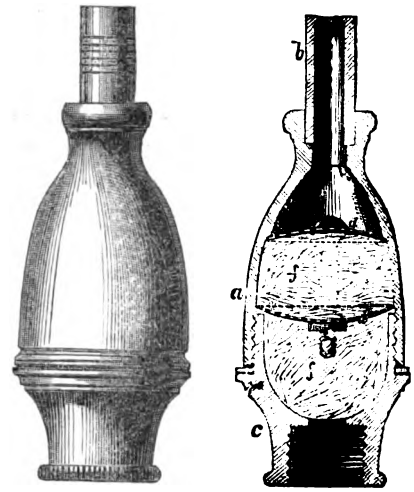


Fig. 1 is an external view, and Fig. 2 a section of it, full size. *a* is the body or principal piece, *b* is the burner-jet which is fixed in *a*, and *c* is the lower part of it which screws into *a*. The thread in the lower end of *c* screws upon the gas pillar or branch like an ordinary burner. Within *a* is placed a diaphragm, composed of two perforated plates *d d*, a piece of loose felt or other like material placed between the plates, and a small threaded rod *e*, with a nut for compressing the felt between the plates. The whole virtue of the burner arises, as we think, from the interposition of the permeable diaphragm, arranged, as shown, between the gas rushing through the pipe and the escape-orifice of the burner. Without the diaphragm the gas rushes out with such a velocity, that it blows the flame out and about, and produces those perpetual variations both in the extent and the position of the flame, which are so fearfully trying to the sight. With the diaphragm, the excessive speed is checked, the gas escapes slowly and steadily, all that so escapes is burnt, and a bright and steady flame results. A small piece of loose felt, *f*, is placed in the lower piece *c*, as shown, to receive any deposit which grossly impure gas may leave behind. This piece of felt can be changed at any time if necessary, it being only needful to unscrew the part *a* from the part *c* for the purpose. Mr. Hart has already found it necessary to provide large works for the manufacture of the improved burners, in order to meet the very large demand made for them. And as doubts have been felt by some respecting the precise manner in which the burner acts in brightening and steadying the light, and economizing the gas, he has offered £50 for the best essay submitted to him upon the subject.

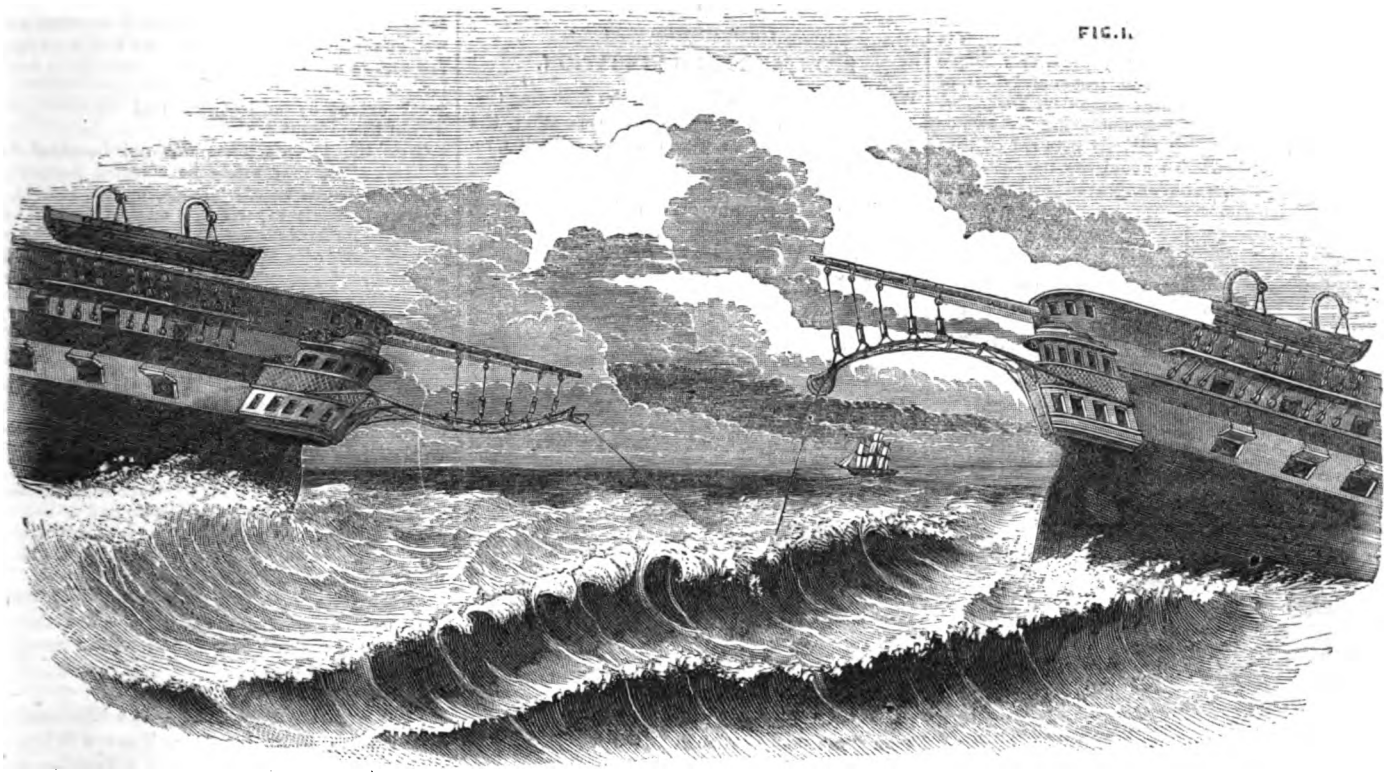
CONYBEARE'S PATENT APPARATUS FOR LAYING SUBMARINE TELEGRAPH CABLES.



CONYBEARE'S PATENT APPARATUS FOR LAYING SUBMARINE TELEGRAPH CABLES.

IT will be recollected that at the last meeting of the British Association Mr. H. Conybeare, C.E., of Abingdon-street, Westminster, read an interesting paper on a new apparatus devised by him for laying submarine telegraph cables. The paper was shortly after published in our columns, and was as follows:—

"My invention consists in the construction of machinery composed of a resilient and articulated series of segments or frames, which extend from the stern of a vessel employed in the submerging of submarine telegraph cables, and over which machinery the cable is to be paid out, being delivered from a trumpet-mouth shaped congeries of friction rollers, situated at the outer extremity of the frame furthest from the stern, in which machinery the resiliency decreases gradually from that part of the apparatus next to the stern to the extreme outer end thereof in a manner similar to that in which the resiliency diminishes from the butt to the top joint of a jointed fishing rod.

"The articulated joints or segments of the apparatus are formed of frames, each frame, starting from the stern, being smaller than that supporting it. Strong springs, such as coach springs, fixed to one frame and linked to the further extremity of the vessel, are employed to give resiliency to the articulations between each frame and that next to it, and the frame furthest from the stern terminates in a semi-conoidal or trumpet-mouth shaped debouchure, consisting of rings of friction rollers breaking joint with each other, and so arranged as to present a rolling surface of moderate curvature to the escaping cable, at whatever angle with the course of the ship it is compelled by side currents or leeway to quit the apparatus.

"Over this resilient and articulated series of frames is a rigid spur of wood or metal, having suspended from it outward as many pulleys as there are joints in the apparatus last described. An equal number of pulleys is provided inboard. A rope or chain is connected to the extremity furthest from the ship of each joint, then to a spring or not as deemed necessary, and then, passing over one of the outboard pulleys and one of the inboard, in the rigid beam, is attached to a spring apparatus, so arranged as to give a resiliency graduated according to the position of such a particular piece in the series.

"This spring apparatus consists of a series of wheels and axles. The resilient springs act on the axles in each case, and the ropes or chain leading to the various parts of the laying apparatus are attached to the wheels. The ratio of the diameter of the wheel to the axle varies in each case, according to the amount of resiliency required by the particular joint or frame of the fishing-rod apparatus with which such wheel and axle are connected. Thus, as the delivery extremity of the apparatus is required to be moved through a comparatively large space by the exertion of a comparatively small strain, the ratio of the wheel to the axle in the resilient apparatus pertaining to this end frame is consequently greater than in that appertaining to any of the frames nearer the stern; and thus a graduated resiliency is obtained; or the same end is obtained by the employment of a spindle-wheel like that of the verge of a watch.

"The required resiliency is obtained either by a vacuum or compressed air cylinder, by volute springs, or by springs of vulcanised India-rubber.

"The required graduated resiliency may be wholly obtained by the coach-like springs which give resiliency to the articulation of the frames; the chains or ropes led inboard from each joint over the rigid spar being merely employed to counterbalance the weight of each frame. Or the resiliency may be wholly given by the wheel and axle apparatus inboard."

We are now able to place illustrations of Mr. Conybeare's apparatus before our readers:—

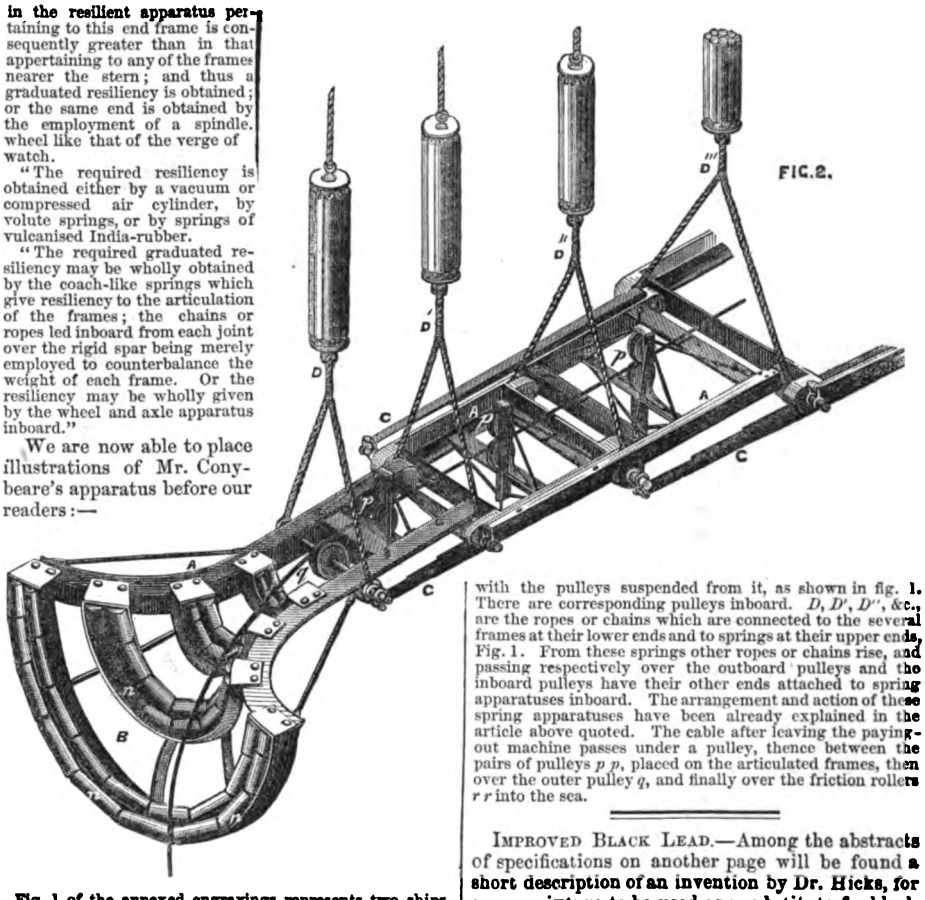


Fig. 1 of the annexed engravings represents two ships fitted with the apparatus delivering the joined ends of the cable in mid ocean. Fig. 2 is an isometrical perspective view of the outer frames and trumpet mouth of the apparatus. *A A* are the articulated frames; *B* is the trumpet mouth on which several sets of friction rollers *n n* are fitted; *C C* are the springs by means of which the resiliency is obtained; there is a rigid spur above the frames with the pulleys suspended from it, as shown in fig. 1. There are corresponding pulleys inboard. *D*, *D'*, *D''*, &c., are the ropes or chains which are connected to the several frames at their lower ends and to springs at their upper ends, Fig. 1. From these springs other ropes or chains rise, and passing respectively over the outboard pulleys and the inboard pulleys have their other ends attached to spring apparatuses inboard. The arrangement and action of these spring apparatuses have been already explained in the article above quoted. The cable after leaving the paying-out machine passes under a pulley, thence between the pairs of pulleys *p p*, placed on the articulated frames, then over the outer pulley *q*, and finally over the friction rollers *r r* into the sea.

IMPROVED BLACK LEAD.—Among the abstracts of specifications on another page will be found a short description of an invention by Dr. Hicks, for a new mixture to be used as a substitute for black lead. We have had specimens of the material submitted to us, and are able to state that, while the cost is but little if at all increased, the polish produced by means of the new mixture is of a very superior character.

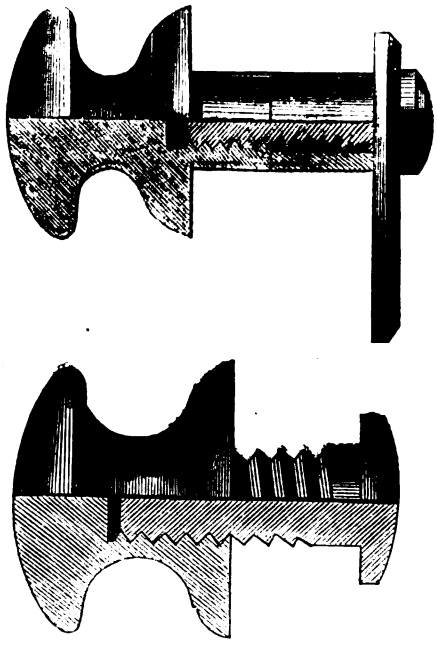
IMPROVED DRAWER KNOBS AND HANDLES.

THE looseness of drawer handles, though comparatively a trifling matter, is so very common a source of annoyance and trouble, that we think it desirable to bring to public notice a very simple form of handle which Messrs. Dixon and Sons, of the Steeton saw mills, near Keighley, Yorkshire, have been extensively manufacturing for two or three years, and which entirely gets rid of that cause of irritation. To avoid the necessity for verbal description, we have engraved two handles of



the improved form, and from these it will be seen that the expedient of the inventors (Messrs. Heywood and Dixon) merely consists in screwing into the knob or handle, from the inside of the drawer, a plug or stop to prevent its withdrawal. This device is so simple, and at the same time so useful, that we need not add a word in its favour. The handles can be obtained, we believe, in any quantity, from Messrs. Dixon and Sons, at the above address.

DIRECT PORTSMOUTH RAILWAY.

THE opening of a direct route, by which Portsmouth can be reached in two hours and a quarter by the ordinary express trains, to say nothing of the saving of time, is of too important a nature to be wholly omitted from our columns. The advantages that thus accrue to our marine and military powers are very great, and must be obvious to all reflecting minds; while, by bringing the coast and the marvellous evidences of England's greatness so much nearer to the metropolis, it affords additional facilities to its inhabitants to visit, either for business or pleasure, that most attractive portion of our isles. By the old routes, a day did not afford sufficient time for even a hurried visit to the dockyards, arsenals, &c.; but, by the present arrangements, the public may leave London even at the advanced period of half-past eleven, and, by returning at half-past seven, p.m., have quite five hours and a half at their disposal. The all-absorbing question of a great city's health is likewise intimately advanced in thus bringing within breathing distance the strength-inspiring breezes of the ocean. Southsea Common, and its admirably-kept promenade, will doubtless see more visitors during the following summers than usual; and the conventional guinea-fee will find its way into the coffers of the South-Western Railway Company rather than into the palm of the physician, in many cases with greater benefit to the patient. The new line turns off at Woking, and, calling at Guildford and Godalming, passes through some of the most lovely and picturesque scenery in Surrey. Indeed, from the constant succession of rustic bits and extensive views of hill and dale, it might not be inaptly termed, "The Artist's Line."

SPONTANEOUS GENERATION.

WE are indebted to a friend for the following:—

The question of spontaneous generation, the dangerous ground on which many scientific reputations have been shipwrecked, is now attracting great attention in France, and is likely to become again a *cause célèbre* before the French Academy. It will be remembered that an English philosopher, Mr. Crosse, endured for many years what may be termed a persecution of scientific orthodoxy on account of his adherence to the doctrine of generation *per se*. It would by no means be an unprecedented fact if the conclusions of our English *savant* should become rehabilitated by the researches of subsequent experimenters. When a little clean hay or other organic matter is placed in distilled water, and exposed to the air at ordinary temperatures, numbers of plants and animalcules speedily make their appearance in the fluid. It has been assumed, and not without reason, that these organised bodies proceed from germs floating in the atmosphere, and becoming fecundated under favourable conditions. For if we allow air to reach the infusions only after passing through a corrosive fluid, such as oil of vitriol, we can then discover no traces of organic life. It is now, however, affirmed that the conclusions hitherto drawn from this fact are disproved by the experiments of M. M. Pouchet and Houzeau. The former *savant*, whose researches on fecundation have been crowned with the completest approbation of the *Académie des Sciences*, states that, after every imaginable precaution having been taken to exclude the external atmosphere from the air and water contained in a flask, he has clearly witnessed in this water the spontaneous growth of various fungi and infusoria among others a plant which will in future be designated *Aspergillus Pouchetii*. According to M. Montagne, this cryptogamic plant belongs to an entirely new species. In a second series of experiments performed in conjunction with M. Houzeau, a chemist well known to the Academy, a portion of hay which had been exposed to a temperature deemed sufficiently high to destroy any animal or vegetable germ, was enclosed with air and water, purified with extreme care. In this mixture, nevertheless, was observed the wonderful generation, not alone of the famous *aspergillus*, but of many species of infusoria. In considering these experiments, we are forced to admit either that spontaneous generation is an indisputable fact, or, on the other hand, one of those hypotheses, viz.: That organic germs may withstand a considerable elevation of temperature; or that the precautions taken to avoid all contact with the external air in these experiments were inadequate. On this point we may anticipate a long and vehement controversy; but we may hope that ultimately there may be but one opinion respecting the doctrine which is now supported by the names of at least two men eminent in scientific acquirements. The question is the more important, inasmuch as the theory of metamorphosis, which assumed that certain algæ might become transformed into various lichens and mosses, or even into infusoria, is now completely disproved.

INVENTIONS AND INVENTORS OF TOOLS.

THE inventors of tools have been great contributors to the present high state that England occupies in the world. Yet how little do we know of them. If you would open your valuable pages for such a subject, I doubt not that much interesting matter might be forthcoming. He who invented the method of cutting screws with stocks and dies was a great benefactor of his species; yet his name is not known, though the invention was so recent, about thirty-six years ago, I was told by a man of eighty-three years of age, that in his early days they cut up *all* screws by hand—the small by filing, the large by chipping and filing. They used a taper tap for nuts of several sizes, the tap being worked in until the nut would go on to the screw. At that time very few screws were used, the cotter, cotteril, or forelock, being used instead. Cotters were used to a great extent by millwrights and wheelwrights within the present century.

That the joiner's plane was not invented in Galileo's time, may safely be affirmed from the following words in his "Dialogues on Motion." Speaking of his experiments on the descent of bodies on inclined planes, he says, "I took a rule, or rather, plank of wood, about 12 yards long, half a yard broad one way and 3 inches the other, we made upon the narrow side or edge a groove a little more than an inch wide: we cut it very straight, *and to make it very smooth and neat, we glued upon it a piece of vellum*, polished and smoothed as exactly as possible, and in that we let fall a very hard, round, and smooth brass ball, raising one of the ends of the plank a yard or two at pleasure above the horizontal line." Now, had the flat plane then been invented, Galileo would have placed two flat boards together angularwise, to make a trough, if he had not had a hollow plane. What an amount of labour must have been required in the ancient palaces and temples before the invention of the plane!

J. SIMON HOLLAND.

P.S.—Can any of your readers give the origin of that very useful tool to engineers, the hanging tool for turning?

THE CASE OF HENRY CORT.—At a late meeting of the South Wales Institute, Thomas Webster, Esq., M.A., F.R.S., the eminent patent-law barrister, read a very interesting paper on "Henry Cort's Invention of the Puddling Furnace and the Grooved Rollers in the Manufacture of Iron," with the official report of which we are now favoured. We shall not publish this report, because the series of papers on the Cort case by the same author, of which the first was published in No. 2, New Series, (and which has been somewhat delayed by the pressure of the author's professional duties) will probably contain all that is essential in it. It is a source of great satisfaction to know that so distinguished a lawyer as Mr. Webster has, in several instances, afforded great inventors and their successors the advantage of his skill and experience in placing their claims dispassionately and truthfully before the public. We do not often meet with like liberality and patriotism among gentlemen at the bar. We hope to resume the publication of Mr. Webster's articles in our next number, and to continue them without material delay.

YATES' PATENT FURNACE.—A furnace which is now, and has for some time been, in operation at the large distillery, Bromley, near Bow, well deserves the attention of persons interested in the modern question of smoke prevention. It is the invention of Mr. W. Yates, the Engineer of the works, a man of fifty years' experience in the profession. The remarkable facts connected with the furnace are, that nothing but coal screenings are burnt, and yet no smoke whatever is produced. The coal, no matter how small, is fed into a hopper or upon a front plate, and by means of a simple apparatus driven by a small shaft from the steam engine, is forced gradually forward into the furnace. The gases distilled from it pass the whole length of the fire-bars over the incandescent fuel, meeting as they pass along with the air rising through the bars, where alone it is admitted. That a good deal of carbonic oxide may escape unburnt from the furnace we do not doubt; but that the emission of smoke is prevented, and great economy obtained by the use of nothing but the cheap screenings of coal, is beyond question. The furnace is also worked with great ease, requiring but a very moderate amount of attention from the stoker.

NOTICES.

THE THEORY OF NAVAL ARCHITECTURE. — We have reluctantly postponed the publication of our third article on this subject for a week. It contains a new investigation of a highly important and somewhat difficult mathematical problem, and involves the elaborate use of symbols, which require great care in passing through the press. We have, therefore, preferred to delay it rather than to risk inaccuracy by undue haste.

Numbers 1845 and 1846 of the MECHANICS' MAGAZINE (original series), containing the paper read at the Society of Arts, Dec. 15, 1858, "ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWERS OF ATTACK AND DEFENCE," by one of the EDITORS of this Magazine, together with the discussion upon the same, are still on sale.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 6d. per line for any number of insertions less than 13; for 13 insertions, 5d. per line; and for 52 insertions, 4d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can be received after 9 o'clock on Friday morning for the ensuing number.

TO CORRESPONDENTS.

X. Y. Z.—We have expressed no opinion respecting the merits of "A Mechanic's" articles on the "Conservation of Force;" nor have we shown any anxiety to shelter the writer from adverse criticism. We have, however, resolved to admit no such criticism until the series of letters is completed; and this we have done to prevent confusion. We have no desire to avoid the thorough discussion of the subject; on the contrary, we court it. But while no severity of reasoning will lead to the exclusion of correspondence, mere severity of language alone will find no place in our columns. There must be a careful conservation of the force of argument in your letter, or it will not appear. All letters must be privately authenticated by the writer's name.

ENGINEER.—Our statement relative to the further enlargement of this Magazine referred merely to a probable increase in the number of pages. We find the present *form* of the Magazine so much approved that we have not the least desire to alter it.

☞ The practice of publishing a vast quantity of fictitious Notices to Correspondents has become so general in cheap journals, that the public, who are not in the secret, have come to consider it the duty of Editors to answer any and every question that may be put to them by readers. This cannot, however, be done in a journal like our own without entailing an immense amount of labour (often of a very unnecessary character) upon us. We, therefore, beg most respectfully to decline the task. But in order that our correspondents may not be deprived of all advantage in this respect, we shall, as a rule, publish such queries as may be sent in good faith to us, though not such as appear to be sent merely for the sake of giving trouble. To the published queries other correspondents will, we hope, reply, and their replies shall likewise be published. By this arrangement we shall save ourselves much inconvenience, and at the same time secure, we trust, to our readers all the information they may desire. All questions must be stated simply, clearly, and without circumlocution of any kind; and we shall feel grateful to those correspondents who kindly take the trouble to send such information by way of reply as they may possess. Mere questions of business we shall of course answer ourselves; but whenever calculation, reference to published works, &c., are necessary, we shall dispose of the questions sent as stated above.

CORRESPONDENT'S QUERY.

GENTLEMEN,—An answer to the following queries would very greatly favour—yours, &c. C. R. E.

January 24th, 1859.

A C

B

If a current of electricity be communicated to a wire at *A*, it being discontinued at *B*, would the current pass on to *C*, the *wire maintaining its position*; and would a *great power* be necessary to maintain the wire in the position as shown at *B*? Is there any rule by which the *resistance* necessary to a certain charge could be ascertained?

LIGHT, HEAT, AND ACTINISM.

GENTLEMEN,—It is found that the proportion of light, heat, and actinism in the solar ray is not constant, but varies with the different seasons of the year. In the spring the actine principle is most abundant; in the summer, light and heat are in excess; and when autumn comes the heating rays are most powerful. Now, as the reason of this is not, I think, understood, and as it appears to me that individual rays of light must conspire to produce these changes, I have thought of the following hypothesis by which to explain them. Suppose that the solar atmosphere is uniformly constituted, and sends forth these various rays as the earth is turned to it. The rotatory motion of the sun might harmonize with these considerations, and serve to strengthen the hypothesis. J. ALEX. DAVIS.

LIST OF PATENTS FOR PRESERVING STONE, &c.

Date.	Patentee.	Analysis of Process.
1838.	BETHEL.	Treating with coal tar, oil, caoutchouc, or rosin, &c.
1841.	NEWTON.	Treating with silicate of soda or potash.
1846.	TEYCHENNE.	Treating with coal tar, bituminous matter, tallow, or other fatty substances, linseed or other drying oils, rosins and gums.
1847.	HUTCHINSON.	After being dried in a chamber, the stone or other substance is immersed in a boiling solution of rosin admixed with oils, tallow, or other gummy or fatty matter; or pitch admixed with oils, tallow, or other gummy or fatty matter; or coal tar, with or without pitch or other bituminous substances; or glue, gums, and other cohesive and hard substances boiled into a solution with oil, &c.
1848.	BETHEL.	Immersing in hot tar, bitumen, or rosin with bituminous or tarry oil.
1852.	MORREAU.	Treating with silicate of potash.
1853.	BARRETT.	Treating with sulphur dissolved in vinegar or acetic acid, or shell lac, seed lac, common turpentine, and pyroligneous spirits; or gutta percha dissolved in coal-tar naptha; or limestone, water, alum, beer grounds, gall, &c.
1854.	DAINES.	Treating with sulphur dissolved in oil.
1854.	ASSANTI.	Treating with gutta percha dissolved in sulphuret of carbon.
1855.	BELLFORD.	Treating with silicate of potash.
1855.	GILBEE.	Treating with silicate of potash applied by means of suitable pumps.
1855.	PAGE.	Treating with calcined bee's-wax dissolved in coal-tar naptha.
1856.	RANSOME.	*Treating with a solution of silicate of potash or soda, and afterwards with a solution of choride of calcium, producing silicate of lime in the pores of the stone; or solutions of alumina and baryta; or any two solutions, which, by mutual decomposition, produce by deposition an insoluble mineral precipitate in the pores, or on the surface of the stone, &c.*
1856.	CLARK.	Treating with gelatine, isinglass, fish glue, &c., and afterwards with a solution of tanin or nut-gall, sumac or oak bark, &c.
1856.	BROOMAN.	Coating first with a mixture of flour, water, and carbonate of lime, then with a mixture of silicate of potash, phosphate of soda, sulphuret of baryta, zinc-white, and borate of manganese.
1857.	SZERELMEY.	Coating with a mixture of water, blood, ground bricks, powdered copper slag, powdered iron slag, argillaceous earth, and caseous matter produced from milk, boiled together, and afterwards with a mixture of gas or coal tar, or linseed oil, or rosin, or asphalte, with hydraulic lime, grit, and calcined flint, boiled together.
1857.	PAUL.	Treating with aluminates of potash, soda, or any other aluminates, or zincates of potash or soda, or phosphates of alumina, or zinc in solution by alkalies; also similar preparations of lead or molybdenum.

CAPTAIN NORTON'S RIFLE BULLET.

THE following paragraph respecting Captain Norton's bullet, which was described and illustrated in our last volume, appeared in the *Times* of yesterday:—

"Several experiments have been made at Chatham with a new description of rifle bullet for firing at long ranges, the invention of Captain J. Norton, the result of which has been very satisfactory. The superiority of the balls invented by Captain Norton lies in his coating the bullet with a small film of paper, which considerably lessens the tremendous friction which the ordinary rifle bullets undergo before they leave the rifle, thereby materially diminishing their propelling force and affecting the accuracy of aim. Captain Norton also does away with the ordinary 'plug' at the base, one description of bullet having a nail or screw inserted at the base, and in the other kind the hollow for the powder being very large. More than a dozen of the new bullets were fired at the target, the rifle used being the elliptical bore rifle of Mr. Lancaster, which is in use by the Royal Engineers. The range tried was 250 yards, at which distance the accuracy with which the new bullets carried was exceedingly satisfactory, only three failing to strike the target, one miss being not the fault of the bullet. The superiority of the new bullets over those now in use was very manifest. The ordinary expanding shot for the Enfield rifle requires the purest lead for casting, but in the paper-coated ball of Captain Norton any lead will answer. The mould in which the newly invented bullets were cast was made by Mr. Lancaster to correspond with the elliptical bore of his rifle."

Captain Norton communicates the following:—

"Chatham, 28th January, 1859.

"Dear Captain Norton,—The four last bullets you brought, carried up from 250 yards, the distance I was firing at to-day with the men, very well, two centres—two outers. The four with small cavities, nail at the base, one miss—one centre—two outers—the miss *not* the fault of the bullet.

"Five with large cavity or hollow, two misses—three outers. I think you have hit the right nail on the head in the first mentioned.—In haste, very truly yours,

"GEORGE R. LEMPRIERE."

"N.B.—All the above-mentioned shot were paper-coated, and without any plug at the base, they were cast in a mould made by Mr. Lancaster according to my order to correspond with the elliptic bore of his rifle. Specimens are to be seen at the Museum of the United Service Institution.

"Any kind of lead answers for casting these shots, but it requires the *purest* lead for casting the expanding-shot for the Enfield rifle. For the above reasons, and the greater facility of cleaning out, and the interior of the barrel receiving no injury from the use of the ramrod, I prefer the Lancaster to the Enfield rifle as a military arm.

"Rosherville, 29th January. J. NORTON."

CURRENT EVENTS

IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

[COMPILED BY OUR OWN CORRESPONDENT.]

Birmingham Chamber of Commerce and Trade Marks and Government Contracts—Co-operative Society of Brick-makers—Offences against the Factory Act—The Stephenson Monument—Opening of an Iron Church—Three several Boiler Explosions—Fishermen, and the use of the Rocket Apparatus—Discovery of Fire-brick Clay—Discovery of Ironstone—Railway News—Weekly Tickets on the Oxford, Worcester, and Wolverhampton Line—Railway Casualties—Four Men Killed by a Colliery Explosion—Manchester Association for the Prevention of Boiler Explosions—The Imposts upon British Shipping.

THE Birmingham Chamber of Commerce have determined to memorialize the Foreign Secretary upon the imitation of English trade marks by foreign manufacturers. The memorialists pray that steps may be taken to obtain for British subjects, by diplomatic convention, the protection of registration in France; and likewise to secure to their manufactures protection from fraudulent imitation in other countries. ——As hinted in the MECHANICS' MAGAZINE a fortnight since that they would, the master brickmakers of Birmingham and South Staffordshire have determined not to employ any workmen who belong to the Operative Brickmakers' Union. The same manufactories notices have been posted to the effect that the workmen already employed must cease their connection with the union, or at the expiration of a certain notice leave the works. In defence the Unionists have commenced a movement with the view of establishing co-operative societies for the employment of the men belonging to the Union who may be deprived of work in consequence of this decision of the masters. In Rochdale and other towns, similar societies, it is alleged, exist, and are worked with advantage to the operatives and the profit of the shareholders. The men are holding public meetings of their body in Birmingham and South Staffordshire in advocacy of the movement.——At the instance of the sub-inspector of factories for the district, penalties amounting to £179 9s. have been imposed by the Bury magistrates upon Mr. T. B. Crompton, late proprietor of the Prestolee paper mills, for allowing young persons and women to work after 6 o'clock. At the same time three overlookers were fined £3 and costs each, for obstructing the sub-inspector.——The workmen in the employ of Messrs. R. Stephenson and Co., have met, 500 strong, and inaugurated a movement amongst themselves for contributing to the monument to the late George Stephenson, Esq., who was the founder of the works.——The first iron church in Staffordshire was opened on Tuesday last, at Essington, near Wolverhampton. It has been built by voluntary subscription, at a cost of £850 in all, and will accommodate 260 persons. The contractors were Messrs. Hemmingsley, of Bow.——One of three boilers, 36 ft. by 6 ft. 6 in., at the Felling Colliery, Gateshead, has exploded, and killed the fireman, whose body was found at a distance of 100 yards from the original site of the boiler. The cause of the explosion has not yet been ascertained. One of the minor results was the knocking of a locomotive off the neighbouring line of rails.——At the brickworks at Wilnecote, near Tamworth, of Mr. Joseph Arnold, a boiler exploded last week, without, however, injury to anyone, the men having just before removed to a distant part of the yard.——On Saturday, the steam-tug *Gleaner*, of Sunderland, towed a raft of timber to Cambois, Blyth. On leaving there again, and while crossing the bar, her boiler burst, and five men who were on board were scalded, two of them severely. The steamer's anchor was put down, but she soon parted from it, and went ashore upon the rocks to the northward of Cambois.——At their own request, the fishermen of Newbiggen, Blyth, have been exercised in the use of the rocket apparatus for saving life from shipwreck.——The discovery of a seam of fire-brick clay has been made in Commondale, about 12 miles beyond Stokesley, on the North Yorkshire and Cleveland Railway. It is 12 feet in thickness, underlies about 12 acres, is without intervening shale, contains only 1½ per cent. of dileterious substances, is nearly black, and can be drifted out of the hill-side. The discovery must be good news to the shareholders of the railway named.——Not less so to the shareholders of the Oxford, Worcester, and Wolverhampton Railway, that iron-stone had been discovered at Handborough, eight miles from Oxford, where that line has only a little agricultural traffic. After being tested, the stone is found to be of about the same quality as the Northampton ore. It will soon find its way into the extensive South Staffordshire market, where large quantities of Northamptonshire "stuff" is now smelted.——The directors of the Lancashire and Yorkshire and those of the East Lancashire Railways respectively recommend a dividend upon the half-

Digitized by Google

year at the rate of 4 per cent. per annum, each carrying surpluses to the reserved fund, the former in addition charging for rails for future use and for past parliamentary expenses no smaller a sum than £23,500.——The Oxford, Worcester, and Wolverhampton directors recommend a dividend of 6 per cent. per annum on the first, and 3 per cent. per annum on the second preference shares.——The Oxford, Worcester, and Wolverhampton Railway commenced on Monday to issue weekly tickets for that portion of their line between Dudley and Wolverhampton.——On Tuesday morning the axle of the guards' van in a train on the Lancashire and Yorkshire broke and threw the carriage off the line as the train was near Dixon Fold. The train was stopped, and a passenger in getting prematurely out of his carriage on the wrong side was killed by a train which was passing at the time on the other line of rails.——On Monday evening, about 7·30, a passenger train on the Great Western Railway was between Shiffnal and Oakengates approaching Wolverhampton when coming into collision with the tail of a train of waggons that seemed to be escaping from a siding, the engine was thrown off the rails and across the line, and the passengers well shaken.——Four lives were sacrificed in the Byeras Colliery, Burslem, on Saturday, by gas being turned out of some old workings into the pit, where men were at work with defective lamps.——The monthly meeting of the committee of management of the Association for the Prevention of Steam Boiler Explosions was held in Manchester on Tuesday last. The report showed that there were 558 mills and other works, and 1,593 boilers under inspection. Out of 668 boilers examined since Dec. 27, 76 had been found defective, 9 dangerously so.——During a conference on Saturday between Mr. Lindsay, M.P., and the Shields Shipowners' Society, that hon. member is understood to have stated that the Government would relieve the shipping from the timber duties, Trinity House charges, passing tolls, and local dues on shipping applied to other than shipping purposes. Mr. Lindsay also stated that a committee would be appointed to inquire into all grievances under which the shipping interest at present labours.

NOTES FROM THE SOUTH WEST.

[FROM OUR OWN CORRESPONDENT.]

The Screw of the "Mersey"—An American Commander on the Great Spithead Review of 1856, and the British Navy—The Royal Albert Bridge—Local Private Bills for the consideration of Parliament — Bristol as an Emigration Port—Cheaper Legislation for Private Objects—Bristol Port Improvements—Women and Watchmaking — Gloucester Trade—Pier at Burnham — The "Nepaul" Steamer—The "Czar"—Mail Communication with the Mauritius—Orders for Machinery—Southampton Inner Dock.

THE screw just received for the *Mersey* frigate is found to be too large, or, at any rate, will involve the enlargement of the space allotted for its accommodation.——Who does not remember, even in this hurrying and forgetful age, the great naval review at Spithead, in the spring of 1856? Commander Walker, of the United States navy, who witnessed the review, has certainly not forgot it, for in a report to his government, recently published, he characterizes that great display of our naval strength as magnificent. The war with Russia, he considers, afforded no indication of the decay which some think may be discerned in the energies of Great Britain; but, on the contrary, after two years, in which Russia was made bankrupt, and France struitened, the strength of England, he thinks, was but roused into full activity. Immense manufacturing energy was revealed, and the Commander thinks there is no reason to believe that had the Government required it, a force of small steamers five times as great could not have been equipped, as one single establishment—that of Penn, of Greenwich—accepted an order for eighty 60-horse engines, to be completed within three months, which they not only fulfilled in the time agreed upon, but put the engines on board the vessels for which they were designed. The Commander notices the fact that there was one type of engine for each class of steamers, and shows that by a judicious distribution of spare parts on board each, no vessel was burdened with a load of machinery, and yet no accident or break-down could occur in a squadron which might not on the spot be repaired. So far as Commander Walker is concerned, Brother Jonathan does full justice to John Bull.——The splendid Royal Albert Bridge, on the Cornwall Railway, is expected to be completed in May. In the construction of this bridge 2,700 tons of wrought iron and 1,200 tons of cast iron have been used; and the fabric comprises, also, upwards of 15,000 cubic yards of masonry and brickwork, and upwards of 15,000 cubic feet of timber. The stone piers at the water's edge are 190 feet high, 29 feet wide, and 17 feet thick; and the length of each arched tube is upwards of 450 feet. The entire length of the bridge exceeds that of the Britannia by 300 feet, so that in some of its details it even transcends that marvel.——Among the private bills which will come before Parliament during the ensuing session, are the following: Bridport Railway; Dartmouth and Torbay Railway, Lymington Railway, Poole and Bournemouth Waterworks, Ringwood, Christchurch, and Bournemouth Railway, Shepton Mallet Waterworks, Somerset Central Railway, Swanage Railway and Pier, Tavistock Markets, Streets, and Improvements, Weston-Super-Mare Improvement and Market, Weymouth and Melcombe Regis Markets and Pier, &c., &c.——It appears that the Bristol Chamber of Commerce presented a memorial to the late colonial secretary, (Mr. Labouchere,) with regard to the capabilities of Bristol as an emigration port. No reply was given to the memorial, but favourable communications have been received from Melbourne and Sydney in answer to petitions presented to the legislative assemblies of Victoria and New South Wales. The question is still not "lost sight of."——An important passage occurs in the voluminous and extremely able annual report just presented to the members of the Bristol Chamber of Commerce. The report calls attention to the bill carried to a second reading last session by Mr. Paull, M.P. for St. Ives, and afterwards withdrawn. The object of Mr. Paull's bill was to enable localities to bring any proposed public improvement in connection with docks, piers, &c., before the board of Admiralty, and after due enquiry, to obtain an act of parliament, as a public act, which would involve much less expense than is incurred under the present system. The chairman of the meeting at which the report was presented (Mr. P. W. S. Miles), made an interesting speech, and a passage or two is subjoined. Mr. Miles observed that it appeared to him that the trading classes of Bristol should not relax their efforts to carry out the objects they had at heart, —viz., the provision of better accommodation for large sailing ships and ocean steamers. He could not help thinking that a report given on the subject by Mr. Walker was not altogether a satisfactory one. Many years ago, he (Mr. Miles) was connected with a scheme known as the Portbury Pier, the principal point being that there should be a large floating pier off Porsit. If Mr. Brunel thought such a pier feasible there, where the run of the tide is stronger than at Kingroad, how was it that a similar scheme was not feasible at the mouth of the river? He had the highest opinion of Mr. Walker, but he should have a very poor opinion of the Board of Admiralty if everything which Mr. Walker said was to be taken for granted. There were, no doubt, other engineers to whom such reports were referred. In regard to other topics, Mr. Miles added that the branch of the South Wales Railway appeared to be progressing satisfactorily. When completed, it would be of great importance to Bristol, for it was as necessary that communication should exist between South Wales and Bristol as that there should be adequate accommodation at the mouth of the river. Another speaker stated that he had heard that there was some thought of an effort for straightening the river. This, he said, would be a good thing, no doubt; but it would not bring a better or a larger class of ships than Bristol had at present. The river was quite good enough for the present trade, but the object should be to attract a different class of vessels, and he hoped the efforts made on the subject would yet be successful. ——Mr. Bennett, who has been lecturing in the metropolis on the desirability of employing women in watchwork, is visiting some of the leading provincial towns for the purpose of developing his views on the subject. Yesterday week Mr. Bennett was at Bristol; and, in addressing a meeting there, he drew a vivid comparison of the poor English sempstress, earning sixpence by eighteen hours of incessant toil, the factory hand, separated from her domestic duties, and the thousands of girls cast, for want of work, upon the streets of the metropolis and large cities of the country, and the mother and daughters of a Swiss family in the midst of the Alps, minding the children, milking the cow, and at the same time obtaining a large sum by making the lighter portions of a watch. On the one hand, grinding penury and dismal vice; on the other, Arcadia, with a useful dash of the commercial element. Mr. Bennett makes no secret of the fact that there is in the trade a powerful combination of men against the employment of women, but states that the very persons who take the most violent part in it are fain to send to Geneva for some portions of watches, which can in no way be made so well as by the delicate touch of the female hand. Mr. Bennett also intimates that he has some intention of establishing a school for the training of women in the business out of his own resources.——It is stated that Messrs. Dent & Co., the eminent glovers, propose to open an establishment in Gloucester, at which 1,000 persons will be employed. The shipping trade of Gloucester shows a satisfactory increase in 1858, as compared with 1857.——At Burnham (at the foot of the Mendip Hills) a pier—referred to as "a great desideratum"—is approaching completion, under the superintendence of Mr. Scott.——The *Nepaul*, new screw steamer, belonging to the Peninsular and Orientrl Steam Navigation Company, has arrived at Southampton from Blackwall, where she was built by the Thames Iron Shipbuilding Company. The *Nepaul* is 1,000 tons burden and 200 horse-power; length between perpendiculars, 320 feet; beam, 30 feet. The machinery is by Messrs. Humphrys and Tennant, and the engines are direct acting; the boilers are Lamb and Summers' patent. The *Nepaul*, which has accommodation for 60 first-class and 20 second-class passengers, averaged 10¼ knots in her voyage from the Thames with a stiff breeze against her. She is destined for the Malta and Marseilles station. In a trial trip in Stokes Bay, on Saturday, she made 12¼ knots.——It was stated last week that the *Ceres* steamer struck on the Lizard Point and foundered. The name was misreported in the original despatches published on the subject, the *Czar* being the lost vessel. The *Czar* was built only a few months since by Messrs. Samuelson & Co., shipbuilders, of Hull, and was one of the largest vessels ever turned out at that port. She was provided with a patent lifting-screw and all the latest improvements. ——The Union Steamship Company have submitted to the Government of the Cape Colony a proposal for the extension of mail communication with the Mauritius by the establishment of branch steamers calling at Port Elizabeth and Natal. The estimated guarantee required is £22,000, one-half to be provided by the Imperial Government.——Messrs Summers and Day have been directed by the Government to proceed with the construction of the machinery of two dredging vessels, in addition to an engine of 800-horse power, for the Royal Mail Steam Packet Company. ——The enlargement of the inner dock, Southampton, is progressing rapidly, and it is expected that the dock will be ready for the reception of ships in April. The west and south walls are within a few feet of the coping level. The north wall, which gave way last summer, has been pulled down, and is now again raised above low-water level; it will be a very substantial work. At the lock the work is progressing favourably. The gates are nearly finished, and will shortly be erected. Bridges for the locks are being made on an improved principle by Messrs. Summers and Day, and four jetties on the west side of the dock are being constructed, two being nearly completed. During the last ten months, upwards of £35,000 has been expended on the works.

NOTES FROM THE EASTERN DISTRICTS.

[FROM OUR OWN CORRESPONDENT.]

The Nene Valley Drainage: Dams at Waldersea and Guyhirn—An odd kind of Bricks—The Reclamation of Marshes at Wells-next-the-sea—Approaching Agricultural Meetings in the Eastern Counties—Grievance of a Gas Company—Compartment-built Ships—The Mayor of Lincoln—The University of Cambridge.

THE dispute with reference to the removal of the dams in the Nene at Waldersea and Guyhirn has come before the Wisbeach magistrates, the town council of that place having preferred an information against the Nene Valley Drainage and Navigation Improvement Commissioners, for causing certain unnecessary obstructions to remain in the river. Mr. F. Jackson, town clerk of Wisbeach, appeared on behalf of the town council; and Mr. Webster, barrister, for the commissioners. The principal witness on behalf of the council was Mr. Thomas Page, C.E., who expressed an opinion that it would be very unadvisable to retain the dams; there had already been very great silting-up in the river, and unless something was done, it would become useless as a port. On the other hand, Mr. Fowler, C.E., was examined on the part of the commissioners, and stated that it would be very inexpedient to remove the dams, in favour of which opinions of eminent engineers have been expressed. The upshot of the application to the magistrates was, that the bench directed that the Waldersea dam should be removed forthwith.——A singular discussion has taken place in the Ipswich town council, Mr. Gowing stating that complaints had been made to him in regard to the bricks used in certain alterations which were being made at the gaol. Mr. Gowing exhibited for the edification of the council a specimen brick, which he crumpled to dust with his fingers. This proceeding elicited loud laughter, and Mr. Gowing was asked whether he had not by mistake got hold of a piece of concrete? A negative reply was returned by Mr. Gowing, who again covered the table with red powder, remarking that the bricks used were of an excessively porous character, because very little clay entered into their composition. He considered that they would decay rapidly, and that the walls of the cell would be damp instead of dry; an animated discussion took place, and the gaol committee were requested to direct their attention to the subject, and deliver a report thereon. ——Reference was made last week to the reclamation of 700 acres of marshes near Wells-next-the-sea, Norfolk. The embankment by which the reclamation is accomplished commences at the foot of the quay, extends in a direct line to the mouth of the harbour, and is 1¼ miles in length; it is 108 feet at base, 17 feet in height, and the footpath at the top is 5 feet wide. A carriage-drive 30 feet wide will be added on the river side, with the view of giving direct communication with the beach, now afforded by a circuitous route by Holkham, where the Earl of Leicester, the prime mover in the matter, has his princely seat.——The three leading agricultural societies of the eastern counties will hold their summer meetings as follows:—Norfolk, at Swaffham, June 16; Suffolk, at Ipswich, June 17; and Essex, at Colchester, July 1.——The Cambridge Gas Company, it will be remembered, applied recently against the poor-rate assessment; and it appears that with a capital expended of £34,000, the amount of their assessment is £2,542; while the expended capital of the Imperial Gas Works, Hackney, is £200,000, and the amount assessed for poor-rate is only £2,000. Several comparisons equally glaring are offered by the Cambridge Company, who consider themselves, and with some reason, deeply aggrieved.——If any doubts were entertained of the greater safety of ships built in compartments, an illustration would be supplied on the subject by a private letter received in Stamford from a midshipman on board the *Feroze*, steam frigate of the Indian Navy, in collision on the 27th of November with the steamer *Pearl*, which conveyed Dr. Livingstone and his gallant comrades to Africa. The midshipman writes that he had just turned in after keeping his watch, and had just gone to sleep, when he was awoke by the noise and "bump" of the collision. The *Pearl*, it was found, had received very serious damage on the port-side, and it was necessary to assist her into the nearest port—Quilon. She was cut seven feet below the water line, and would of course have filled at once and gone to the bottom if she had not been built in compartments ——The Mayor of Lincoln (Mr. Joseph Shuttleworth, of the well-known firm of Clayton, Shuttleworth and Co.,) is about to present to the church of St. Peter-at-Arches in that city an ornamental frame of wrought metal (harmonizing with the other features of the building) for the corporate insignia.——The public have observed with a good deal of pleasure the ready co-operation afforded by the authorities of the University of Cambridge to the movement for rendering the University system more in accordance with the spirit and necessities of the age. It is not at all unnatural that such attention should be given by the Cambridge "heads" to the middle class or "non-gremial" examinations in the leading provincial towns, for as regards the "honour" men, the University has this year barely maintained its position, while the number of candidates for "poll" degrees is very greatly reduced. The number of wranglers, senior optimes, and junior optimes was as follows, this year and at the corresponding period of 1858:—

CLASS.	1859.	1858.
Wranglers	38	42
Senior optimes	47	44
Junior optimes	46	44
Ægrotant	1	4
Total	132	134

As regards the candidates for ordinary or "poll" degrees, the comparison stands thus:—

First class	27	23
Second class	29	54
Third class	31	76
Fourth class	12	20
Ægrotant	3	3
Total	102	176

Digitized by Google

As the gentlemen who have now come out matriculated in October, 1855, the war then raging may have possibly had some influence upon the figures of the present year; but, however this may be, it is clear that there is scarcely the same eagerness as formerly to push young men, whatever their talents, into a university life, under the present system. Hence the effort to make the non-gremial examinations a means of recruiting the university. Of the 131 gentlemen who have taken honours, Trinity College contributed 38; St. John's, 31; Pembroke and Magdalene, 1 each; Sidney Sussex, 5; Emmanuel, 7; St. Peter's, Trinity Hall, and Jesus, 3 each; Clare, 6; Caius, 18; Corpus Christi and St. Catherine's, 2 each; Queen's, 4; and Christ's, 10; Downing and King's do not figure in the list.

METAL AND COAL TRADES, &c.

[FROM OUR OWN CORRESPONDENT.]

The Iron Trade Generally of the Past Week: How affected by the War Cloud—The Iron Trade in South Staffordshire—In South Wales—The Coal and Iron Trade in North Wales: of what the Coal-masters there are apprehensive—The Reports from Derbyshire, Yorkshire, and Lancashire—The Coal Trade in Derbyshire—The Sheffield Trades—The Hardware Trades of Birmingham, Wolverhampton, and their Districts—Metals on the Liverpool 'Change—Glasgow Market—Oxfordshire and the Metal and Coal Trades—The Trade of Leeds in Metals and Fabrics—The State of Things in Manchester, Rochdale, Bradford, Halifax, Huddersfield, Leicester, and Nottingham—The Glass-makers' Dispute—The Colliers of South Staffordshire—Total Exports of Coal from Great Britain in 1858.

MUCH cannot be said for the iron trade as the result of the past week's experience. The war cloud, which it was hoped was dispersing, seems now to have become more charged. As ever, so also now, the demon War is the enemy of trade and commerce in nearly all its branches. On account of the apprehensions which the existing very uncertain and extremely unsatisfactory state of things produces, a check has been felt in the past week to the progress which was so observable a month or three weeks ago. The improvement which then set in has not been maintained in the past fortnight; and its subsidence has been particularly observable in the past seven days. Since our last report, very few orders have come to hand for any description of iron. Some of the houses which stand A 1 on the list of firms, do not yet much feel this, as the orders taken at about quarter day will suffice, with the constantly-recurring necessities of established customers, to carry them through the quarter. With the less conspicuous firms, however, the case is different. These have, for some time, been compelled to exist upon the orders obtained from week to week. They, therefore, feel the recently altered state of the trade; and, as a consequence, have their machinery only in partial activity. Prices for malleable iron are easier this week; and the movement in pigs is in the same direction.

South Staffordshire.—The reports of the several iron-masters on 'Change at Wolverhampton, on Wednesday last, showed trade had not progressed in the past week, from the cause already indicated. Little or nothing was done on that day. On every hand there was a manifest apprehension as to the future, which had far otherwise than a cheering influence upon the whole proceedings.

From South Wales our last advices state that the iron and coal trades are still improving in position. Large quantities of steam coal are being shipped at Cardiff, but the trade of Newport is rather depressed. Railway iron is being disposed of freely, and pigs are likewise sought after. The principal demand is for home consumption, at the present moment, but some good orders are received from the continent.

We learn from North Wales that a good trade is being done in iron, stone, and coal. The coal masters, however, are fearing an increase of toll by the Great Western Railway Company, as the result of a bill which that company purpose introducing into Parliament on an early day. Some mines at Ruabon belong to persons connected with that line. In the manufacturing of iron, also, North Wales is tolerably active.

In the reports from Derbyshire, Yorkshire, and Lancashire it is stated the demand for rails is active, owing to the large contracts which are in hand for Australian lines. The inquiry for sheets and plates is also improved. The rates are well maintained, and the makers of first-class brands are full of orders. The pig-iron trade is also in a better state as compared with some weeks ago. The coal trade of those districts is improving, the demand in Derbyshire being largely on the increase. The large pumping engine of the North Derbyshire Mining Company was started on Thursday last for the first time, amid such a display of enthusiasm as is seldom witnessed in a Derbyshire village.

The Sheffield trade is in a better state, since the commencement of the year orders have been given out pretty freely. The orders from America are but small, but the demand from other districts has increased.

Birmingham, Wolverhampton, and their districts are well employed as a whole. The instalments of orders received from travellers out are regarded pretty favourably by the manufacturers.

At Liverpool Exchange on Saturday last the demand for manufactured iron was moderate, and purchasers were cautious in their operations; the prices of common Welsh bars was £6 12s. 6d. to £6 17s. 6d.; Staffordshire, £7 to £7 2s. 6d.; and hoops, £8 7s. 6d. to £9 per ton. In tin plates business was limited, purchasers being unwilling to pay the higher rates generally demanded by holders. Copper continues steady, with a moderate demand; British cake and tile, £112 10s. per ton, and copper sheathing, 1 ¼d per lb. The prices of lead are £21 15s. to £22 per ton for sheet, and £22 15s. to £23 for pig. The pig iron market at Liverpool on Monday was quiet; sellers at 53s. and 53s. 3d. cash, and 54s. three months open; buyers at 52s. 9d. cash, and 53s. 6d. three months open.

From Glasgow we learn that speculation for the moment has closed, and that it shows no signs of being resumed, unless affairs assume a more settled appearance on the Continent.

Oxfordshire (aye, even classical Oxfordshire, gentle reader) is about to furnish material for a paragraph under the heading of "Metal and Coal Trades." A shaft is being sunk on land belonging to his Grace the Duke of Marlborough, in the parish of Northleigh; mining operations are commenced on the estate of Mr. Chamberlain at Adderbury; measurements and levels have been taken for a tramway intended to convey iron ore from Dr. Wilson's estate at Overworton to the Somerton station of the Great Western Railway; while miners in the employ of Messrs. Blackwell and Co., of Dudley, are now procuring from a depth of 35 yards below the surface a quantity of "green stone ore" at Steeple Aston.

From Leeds we learn that the manufacturers of iron in that district are well employed, and for some descriptions of iron are realising a slight advance in price. By an extension of the machinery previously in operation at old works, and by an increase in both works and also machinery, the make of iron in this district is largely increasing. The machine tool trade is manifesting faint signs of awakening from a state of almost torpor. Continental orders are affording considerable employment to the manufacturers of textile machinery. In locomotives there is no great deal doing. The nail-makers are busy.

In textiles, Leeds is an exception to most of the other towns, as well in Lancashire as Yorkshire. Reports from Manchester, Rochdale, Bradford, Halifax, Huddersfield, Leicester, and Nottingham, all show that trade is quieter. The unsettled state of European politics exercises an unfavourable influence. Exports are checked; merchants seem in a state of uncertainty, and operate cautiously.

The glass-makers' dispute is prolonged. A meeting of delegates from the various trades' societies of London was held last Friday in the metropolis to hear the statements of deputations from Birmingham and Stourbridge; and the meeting decided that the glass-makers were worthy of the support of all the trades in London. If they should get it the deputation stated that they could easily resist their employers another six months.

The colliers of South Staffordshire have met and resolved to give their employers notice to-morrow (Saturday) that they must have an advance of sixpence a day upon their present wages, else at the expiration of a fortnight they will cease working and not return to the pits until the advance is accorded. This is a return to half the rate that the men were receiving prior to the last strike in that district.

The total export of coal from Great Britain in the year 1858, as stated in the circular of Messrs. W. and H. Laird and Co., of Liverpool, issued on Friday last, was 6,077,863 tons, showing a decrease as compared with the year 1857 of 148,187 tons. The exports were as follows:—From the Northern ports, 3,592,206 tons; from the Yorkshire ports, 253,649 tons; from Liverpool, 167,478 tons; from the Severn ports, 1,382,277 tons; and from the Scotch ports, 382,262 tons. There was a decrease on the year at all the ports except the Yorkshire ports, where the increase over the year 1857 was 22,785 tons. The total exports for December were 381,077 tons.

Patent for Inventions.

PROVISIONAL PROTECTIONS.

Dated December 10, 1858.

2832. J. Bethell, of Parliament-st., Gentleman. Improvements in machinery and apparatus for the preservation and colouring of wood.

Dated December 31, 1858.

3004. J. H. Sievers, of Rathbone-place, Oxford-st., Gentleman. Apparatus for tightening and releasing the belly bands of riding saddles. A communication from C. Zipp, of Paris.

Dated January 3, 1859.

28. E. Balchin, of Hull, Gun Maker. An improved construction of projectile, applicable to the whale fishery.

Dated January 7, 1859.

52. I. Holden, of St. Denis, near Paris, and A. Holden, of Bradford. Improvements in means or apparatus employed in preparing and combing wool and other fibres.

54. J. J. Florence, of Paris, Merchant. Improvements in reels or spooling-wheels.

56. A. Barclay, of Kilmarnock, Engineer. Improvements in electric and magnetic telegraphs.

58. H. Reynolds, of Denmark-hill, Gentleman. Improvements in refining and decolorizing saccharine substances.

Dated January 8, 1859.

60. H. Harden, of Dundalk, Ireland, Locomotive Superintendent. Improvements in fire bars for steam boiler and other furnaces.

62. D. Friedlaender, of Manchester, Tobacconist. An improved smoking pipe.

64. F. Versmann and A. Oppenheim, of Bury-court, St. Mary Axe, Analytical Chemists. Improvements in the treatment of various substances, by which to render the same uninflammable.

Dated January 10, 1859.

72. R. D. Clegg, of Manchester. Improvements in signalling apparatus.

74. T. J. Claxton, of Montreal, Merchant. Improvements in the manufacture of boots and shoes. A communication from M. Bray, of Montreal.

76. J. S. Margetson, of Cheapside. An improved box or case, suitable for hats, collars, and other useful purposes.

Dated January 11, 1859.

80. C. M. Kernot, of West Cowes, Isle of Wight, Doctor of Medicine. Improvements in purifying and decolorising paraffine, and rendering the same white, hard, and sweet.

82. B. Robbin, of Yarmouth, Nova Scotia, Master Mariner. Improvements in the machinery for working pumps.

84. D. E. Hughes, of New York, Telegraphic Engineer. An improved mode of insulating electrical conducting wires.

86. R. and W. Hawthorn, of Newcastle-on-Tyne, Engineers. Improvements in apparatus for promoting combustion and preventing smoke in coal-burning locomotives and other steam-boiler furnaces.

88. F. Versmann and A. Oppenheim, of Bury-court, St. Mary Axe, Analytical Chemists. Improvements in rendering fabrics and substances non-inflammable.

Dated January 12, 1859.

90. P. Bouché, of Paris, Stays Maker. Improvements in the used means for mechanically raising up the gowns of ladies and young ladies.

91. W. and W. T. G. Bray, of Folkstone, Engineers. Improvements in locomotive and traction engines.

92. W. Oliver, of Shadwell. Improvements in boats, and in the mode of propelling them.

93. J. Thomson, of Dundee, Manufacturer. Improvements in the manufacture of rugs.

94. J. Hands, of Notting-hill, Surgeon. Improvements in preserving or preparing skins intended to be converted into leather, or otherwise manufactured.

95. J. Gibbons, of Oxford-st. Improvements in fixing door and other knobs.

96. S. Canning and H. Clifford, of Leadenhall-st., Engineers. Improvements in machinery for paying out and for recovering or picking up submarine telegraph ropes, cables, or chains.

97. T. Elwell, of Paris, Engineer. Improvements in governors for steam engines and other motive power engines.

98. W. McNaught, of Manchester, and W. McNaught, of Rochdale, Engineers. Improvements in steam engines and in apparatus connected therewith.

99. S. Phillips, of Moseley, Worcester, Gentleman. Improvements in fastenings for securing windows, shutters, and doors, and for other similar uses.

100. R. Mushet, of Coleford, Metallurgist. A new or improved metallic alloy.

101. R. Mushet, of Coleford, Metallurgist. An improvement or improvements in the manufacture of cast steel.

102. C. N. May, of Devizes, Engineer. Improvements in sluice valves.

103. C. Beslay, of Paris, Engineer. Improvements in coating or covering iron or steel with tin, zinc, or lead, or alloys of those metals, by electrical deposit.

Dated January 13, 1859.

104. C. N. May, of Devizes, Engineer. An improved heat indicator.

105. R. A. Lightoller, of Chorley, Cotton Spinner. Certain improvements in machinery or apparatus for spinning cotton or other fibrous materials.

107. W. H. Crispin, of Stratford, Copper Smelter. Improvements in the construction of ships and other sailing and steam vessels.

108. H. Critchley and S. Elston, of Bury, Engineers. Certain improvements in pistons for steam engines or other purposes.

109. G. Scopes, of Needham Market, Suffolk, Bricklayer. Improvements in apparatus for communicating motion to cots, cradles, and other articles for children's use.

110. J. Picksley and R. Sims, of Leigh, Machine Makers. Improvements in lawn mowing machines.

111. W. H. Morrison, of Nottingham, Manufacturer. Improvements in wind musical instruments.

112. D. L. Banks, of Kennington, Engineer. A method of constructing a travelling suspension rail or roadway, applicable, among other uses, as a bridge and lifting agent.

113. J. J. Stevens, of Darlington Works, Southwark, Engineer. Improvements in railway signal apparatuses.

114. F. J. Manceaux, of Paris, Manufacturer, and E. N. Vieillard, of the same place, Gunsmith. Improvements in breech-loading fire-arms and in cartridges.

115. J. Grist, of Beazley-crescent Old Ford, Engineer. Improvements in machinery for cutting and shaping staves and heads for casks, and for the manufacture of casks.

116. W. A. Chadwick, of Wand-sworth-road, Merchant. A musical instrument, chiefly for teaching the intervals of musical scales.

118. T. Herbert and E. Whitaker, of Nottingham. Improvements in the manufacture of warp lace.

119. O. Rowland, of May Fair. Improvements in laying electric telegraph wires in streets.

120. J. Barrans, of Peckham. Improvements in traction and portable steam engines.

121. T. Sampson, of Barcelona, Spain. Improvements in apparatus for feeding steam boilers with water.

Dated January 14, 1859.

122. S. Holt, of Manchester, Silk Manufacturer. A new and improved manufacture of woven silk fabrics.

124. W. Craft, of Hammersmith, and T. Wilson, of Chiswick. Improvements in drawers and napkins so as to render the same waterproof.

125. W. Davis, of Globe-fields, Mile-end. Improvements in sluice valves.

126. J. Danglish, of Tunbridge Wells, M.D. Improvements in obtaining carbonic acid gas.

127. R. Romaine, of Chapel-st., Bedford-row, Gentleman. An improved arrangement of portable railway.

Dated January 15, 1859.

129. W. H. E. McKnight, of Swindon, Wilts. An upright-celled boiler, applicable to all heating purposes by hot-water or other fluid.

131. D. L. Banks, of Kennington, Engineer. Improvements in the method of constructing a travelling suspension rail or roadway, to be used for the cultivation of land.

133. W. Betts, of Wharf-road, City-road, Capsule Maker. Improvements in the manufacture of capsules, and in the apparatus to be employed therein.

Digitized by Google

Dated January 17, 1859.

135. W. Morgan, of Grafton-st., Fitzroy-sq., Gentleman. Improvements in printing and stencilling, and in the apparatus or machinery used therein, also for certain applications of such printing and stencilling.

137. J. Montgomery, of New York. Improvements in the construction of the hulls of steam and other vessels, and in the feed-water heaters, boilers, water-gauges, condensers, engines, and propelling machinery appertaining to the former, a portion of which improvements (with the exception of those on the hull), are applicable to analogous useful purposes.

139. P. A. de St. S. Sicard, of Paris, Chemist. An improved process and apparatus for converting cast iron into steel.

141. W. E. Newton, of Chancery-lane. An improvement in sewing machines. A communication from E. Howe, jun., of Brooklyn.

143. R. G. Salter, of Alphington, Devon, Engineer. Improvements in apparatuses for collecting or picking up letters, papers, and other articles requiring to be stamped or printed.

145. R. Mushet, of Coleford, Matallurgist. Improvements in the manufacture of cast steel.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, Feb.* 1*st*, 1859.)

2126. T. B. Hubbell. Petticoats. A communication.
2127. J. Hope. Printing roller.
2129. T. Howe. Smiths' forges.
2140. D. Grant. Colour-printing presses.
2146. H. H. and W. F. Henson. Waterproofing.
2147. R. Bodmer. Preventing explosions in steam boilers. A communication.
2150. G. L. Fuller. Steam engines.
2161. W. Lander. Engraving and printing.
2164. E. Lewthwaite and G. Ambler. Timepieces.
2165. B. Jones. Clod crushers.
2172. G. T. Bousfield. Paper bags. A communication.
2203. L. A. Normandy, jun. Sulphate of copper. A communication.
2206. J. Mills. Roving, slubbing, &c.
2209. W. Menelaus. Straightening rails and bars.
2241. W. A. Munn. Horse-shoes.
2245. J. T. Smith. Electric cables.
2246. E. Birchley. Cartridge.
2270. L. Wray. Insulating telegraph wires.
2271. T. C. Shaw and F. H. Cooper. Motive power.
2287. L. Cowell. Apparel for preserving life at sea.
2289. A. Gordon. Cast iron, steel, and wrought iron. A communication.
2301. W. Bacon. Valves, &c. A communication.
2343. R. Griffiths. Baths.
2351. J. M. Napier. Printing machines.
2382. A. V. Newton. Candles. A communication.
2479. R. E. Pinhey and J. Wood. Ships' compasses.
2613. G. Howe and J. Norton. Boiling water.
2627. A. J. Thorman. Chain cables.
2671. C. E. Amos. Raising ships.
2687. M. Meyers. Parasols.
2746. G. W. Bales. Door sashes, &c.
2836. R. A. Brooman. Cranked axles and shafts. A communication.
2931. J. J. Welch. Neck-ties.
28. E. Balchin. Projectile.
52. I. Holden. Preparing fibres.
53. E. Heywood. Weaving.
56. A. Barclay. Telegraphs.
77. J. White. Purifying air.
93. J. Thompson. Rugs.
94. J. Hands. Preparing skins.
105. R. A. Lightoller. Spinning.
113. J. J. Stevens. Railway signals.
115. J. Grist. Casks.
124. W. Craft and T. Wilson. Drawers and napkins.
126. J. Dauglish. Carbonic acid gas.
127. R. Romaine. Portable railway.
137. J. Montgomery. Steam vessel, &c.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed January 28, 1859.

1714. J. Brierley.
1716. J. F. W. Featherstonhaugh and F. Wise.
1722. J. Watkins.
1723. C. and F. Schiele.
1725. T. Webb and J. Craig.
1726. J. Davey, H. Sims, J. Mayne, W. Hodge, and J. Gerrans.
1729. J. S. Bailey.
1733. G. Ashcroft and H. W. Wood.
1734. G. Davies.
1736. H. Conybeare.
1737. H. Conybeare.
1750. J. L. Norton.
1758. R. Cunningham.
1760. G. Bell.
1763. J. Greenwood.
1768. J. Taylor.
1776. J. Luis.
1859. A. Slate.
1946. W. E. Newton.
1950. J. Ireland.
1978. A. V. Newton.
2046. J. Wright, sen., and J. Wright, jun.
2156. C. Hall.
2310. T. W. G. Treeby.
2317. B. Nickels.
2399. J. W. Mott.
2452. H. Tertian-Moret.
2498. W. Smith.
2606. J. M. Miller.
2652. E. H. Bentall.
2660. A. V. Newton.
2698. R. Alexander.
2721. J. Gresham.
2754. L. MacKirdy.
2755. L. Mac Kirdy.
2767. C. Coates.

Sealed February 1, 1859.

1744. J. W. Schlesinger.
1747. S. Hine.
1766. C. Callebaut.
1779. J. Luis.
1785. R. A. Brooman.
1794. S. Carey.
1795. G. Weston.
1820. R. H. Collyer.
1837. J. Fogg.
1893. F. Preston and W. Macgregor.
1924. J. Macintosh.
2037. A. M. Peters.
2373. W. E. Newton.
2416. W. E. Newton.
2651. A. V. Newton.
2775. R. Pickering.
2821. H. Maudslay.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

222. J. Wormald.
236. D. Foxwell.
254. J. L. Stevens.
255. J. Gretton.
261. H. Tylor.
268. J. B. Anderson.
269. T. Hurst.
287. B. F. Miller.
299. E. S. Robinson.
313. J. Howard.

LIST OF SPECIFICATIONS, &c.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 1223, 1243, 1276.
BOILERS AND THEIR FURNACES, 1244.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1220, 1233, 1252, 1258, 1259, 1260, 1264, 1276.
SHIPS AND BOATS, including their fittings, 1223, 1293.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1232, 1236, 1237, 1265, 1277, 1278, 1281, 1290, 1294.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1271.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1224, 1225, 1240, 1242, 1249, 1256, 1257, 1263, 1270, 1280, 1285, 1297.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 1245, 1282, 1292.
LIGHTING, HEATING, AND VENTILATING, 1248, 1851, 1267, 1291.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1228, 1229, 1230, 1245, 1254, 1261, 1269, 1272, 1286, 1287.
METALS, including apparatus for their manufacture, 1230, 1289.
CHEMISTRY AND PHOTOGRAPHY, 1219, 1230, 1231, 1247, 1251, 1279.
ELECTRICAL APPARATUS, 1239, 1241, 1268.
WARFARE, 1262, 1273, 1274, 1296.
LETTER PRESS PRINTING &c., 1221, 1238.
MISCELLANEOUS, 1218, 1219, 1222, 1226, 1227, 1233, 1234, 1235, 1246, 1253, 1255, 1260, 1266, 1271, 1275, 1279, 1283, 1284, 1288, 1295, 1298.

1218. J. SCHLOSS. *A so-called book-clasp or improved fastening of books, being also applicable to pocket-books, ledgers, blotting cases, and similar articles where locks, bolts, or clasps are employed.* Dated May 29, 1858.

This chiefly consists of a main plate or box containing mechanism for bolting and locking, such as springs, trigger plate with cams, slots, or notches, &c., worked upon by a trigger extending outside of the main plate, and for locking by a key introduced on its outside plate or guard plate; the main plate is made with a hinge plate rivetted or screwed to one side of the book, &c., whilst the opposite side has a similar plate containing a hasp which enters the slot of the bolt when brought near it. *Patent completed.*

1219. J. YOUNG and J. STRANG. *Improvements in the manufacture of starch, gum, or dextrine, and their compounds.* Dated May 31, 1858.

This consists in using whey obtained from milk. *Patent completed.*

1220. J. B. THORNBER. *Improvements in carriages for children, commonly called "perambulators," which improvements are also applicable to invalid and other carriages.* Dated May 31, 1858.

This consists in applying a circular covering or shade. *Patent completed.*

1221. J. B. GIBBD, and P. F. WOHLGEMUTH. *Improvements in ornamental staining, dyeing, and fixing designs, writing, letterpress and type printing and cyphering, and colours, on wood, or any other substances; also extracting, transferring, or discharging colours from the same.* Dated May 31, 1858.

This consists in using for the above purposes metallic salts and oxides. *Patent abandoned.*

1222. G. K. SNOW. *A new and useful machine for affixing postage stamps to letters.* Dated May 31, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1223. W. PARSONS. *Improvements in steam-engines, for propelling vessels and other purposes, and in bearings for the screw-shafts of steam vessels.* Dated May 31, 1858.

Here two steam cylinders are placed horizontally and opposite each other, with their axes at right angles to the main shaft. In each cylinder there is a piston, and these pistons are connected together. Between the two rods there is a vertical slot, and through this slot a bar passes. At one end of this bar there is a ball carried by a socket bearing on a standard; the other end of this bar fits into a socket on the face of the disc fixed on the end of the main shaft. The cylinders may be applied to act on the bar, half way between its stationary bearing and its bearing in the disc, or at any other point. In some cases he employs oscillating cylinders. To support screw shafts he applies a friction-pulley having its axis at right angles to the shaft. *Patent abandoned.*

1224. H. JAEGER. *Improvements in dyeing wool.* (A communication.) Dated May 31, 1858.

After the wool has been cleansed, it is boiled in a bath of some vegetable acid, such as tartaric or oxalic acid. It is next immersed in a solution of murexide. *Patent abandoned.*

1225. W. E. NEWTON. *Improvements in printing and dyeing textile and other fabrics.* (A communication.) Dated May 31, 1858.

Here the fabric passes between the printing cylinder and the colour roller, sufficient pressure being put upon the former to cause it to press the fabric upon the colour, so that, owing to the elasticity of the fabric, only such portions of it will be presented to the action of the colour roller as correspond to the raised portions of the pattern cylinder. A cloth runs between the fabric and the cylinder, to insure uniformity of action, and another fabric is interposed between the fabric to be printed and the colour roller. There are modifications included. *Patent abandoned.*

1226. J. AUSTIN and J. ARMSTRONG. *An improvement or improvements in the manufacture of coke.* Dated May 31, 1858.

This consists in passing a current of steam through the coke when in a state of strong ignition. *Patent completed.*

1227. C. BINKS. *Improvements in manufacturing soap.* Dated June 1, 1858.

This consists in the use of linseed oil. Also in the use of atmospheric air passing through the materials during saponification. *Patent abandoned.*

1228. A. BARCHOU. *A heel for boots and shoes.* Dated June 1, 1858.

This consists of a hollow leather heel. *Patent completed.*

1229. C. F. VASSEROT. *A kind of tramway to facilitate the locomotion of bedsteads.* (A communication.) Dated June 1, 1858.

The inventor fixes under the castors a sheet-iron band, having a small projecting flange on each side; the two rails are nailed to the floor. *Patent abandoned.*

1230 A. G. GRANT. *A method of preparing paper in order to render it waterproof, and adapted for the reception of photographic pictures.* Dated June 1, 1858.

The inventor impregnates paper with a composition of the following materials:—Asphalte, oil, turpentine, Canada balsam, caoutchouc, gum lac, and white wax, with or without chloroform. It is then placed in an oven wherein the heat is raised to a point just below that at which the material will ignite, where it remains until dry, when it is fit for use. *Patent abandoned.*

1231. A. G. GRANT. *An improved stand or rest for cameras, theodolites, guns, and other articles.* Dated June 1, 1858.

This consists of three or more legs which, when brought together, unite in the form of a cylinder. *Patent abandoned.*

1232. R. W. CHANDLER and T. OLIVER. *Improvements in agricultural apparatuses for ploughing and otherwise operating upon land.* Dated June 1, 1858.

This invention was described and illustrated at page 9 of the MECHANICS' MAGAZINE, No. 1, New Series.

1233. J. LANG. *An improved method of signalling on railways.* Dated June 1, 1858.

The inventor fixes along the line horizontal levers, which vibrate with a slight force; these levers are connected by pulleys and cords with each other, and also with a bell or gong, at the stations along the line; the levers are placed so that a stud fixed upon a chimney or other part of the engine will strike them, cause them to vibrate, and thence, by pulleys, cords, &c., act upon the bell at the station, indicating that the engine has passed a particular point. *Patent abandoned.*

1234. F. J. CANDY. *Improvements in machinery for the manufacture of fishing and other nets.* Dated June 2, 1858.

Upon a bed the inventor fits two socket bars with as many sockets as there are shuttles; one end of these bars is furnished with a rack geared into by a toothed wheel, so that, upon giving motion to the wheel, the bars are moved to and fro. The shuttles for holding the thread, &c., consist of frames, each terminating in a foot which fits into the sockets in the carriers. The thread is wound upon spindles mounted in the frame, and capable of moving to wind and give off the thread; just above the foot in which the frames terminate there is a mortice for the reception of

Digitized by Google

fingers. On each side of the machine there is a frame capable of sliding to and fro in a direction at right angles to the socket bars; each frame supports in bearings what the inventor terms a finger bar, with as many projecting arms or fingers as there are sockets. At each side of the machine there are two catch bars carrying wires, which wires are connected to a slide, and hook on, or to set free, the threads. One bar at each side is held upon a cord, the opposite end is passed over a pulley at each end of the machine and attached to balance weights. *Patent abandoned.*

1235. J. MANNHARDT. *An improvement in machinery for the manufacturing of peat fit for fuel, and for the squeezing or forcing of fluids out of the said turf, peat, or similar substances.* Dated June 2, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1236. J. LUIS. *A new farming implement, called the gleaner.* (A communication.) Dated June 2, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1237. J. LUIS. *A new description of plough, with forecarriage applicable to all swing or common ploughs.* (A communication.) Dated June 2, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1238. D. SERVICE. *Improvements in apparatus for producing printing surfaces.* Dated June 2, 1858.

Here a reciprocating tool above the wooden block, heated by gas, is connected to a similar reciprocating tool, which works into the wooden block from below, so that the two tools act simultaneously, one entering the block downwards as the other enters it upwards. *Patent completed.*

1239. C. WHEATSTONE. *Improvements in electric telegraphs, and in apparatus connected therewith.* Dated June 2, 1858.

This consists of mechanism for transmitting messages, and causing them to be printed at a distant station. Long strips of paper are perforated with apertures grouped to represent the letters of the alphabet and other signs; a strip thus prepared is placed in an instrument associated with a rheomotor (or source of electric power), which, on being set in motion, moves it along, and causes it to act on two pins, so that when one of them is elevated the current is transmitted to the telegraphic circuit in one direction, and when the other is elevated it is transmitted in the opposite direction. The elevations and depressions of the pins are governed by the apertures and intervening intervals. These currents following each other indifferently in two opposite directions act upon a printing instrument at a distant station so as to produce corresponding marks on a ribbon of paper moved by appropriate mechanism. *Patent completed.*

1240. H. BROWN, B. HODGSON, and J. CARTER. *Improvements in machinery for introducing and withdrawing wires when weaving.* Dated June 2, 1858.

Here each of the wires is made with an enlarged head, on one side of which is a vertical groove, so that the instrument which draws the wire out of the fabric, and moves it into a fresh shed in the warp, may for the time act on such head, and readily leave hold thereof. The instrument for drawing the wires out of the fabric, and introducing them into fresh sheds in the warp, consists of a sliding vertical bolt, which moves between V guides, carried by a sliding frame, moving in horizontal V guides in a direction to and from the reed. *Patent completed.*

1241. C. WHEATSTONE. *Improvements in electro-magnetic telegraphs, and apparatus used for transmitting signs or indications to distant places by means of electricity.* Dated June 2, 1858.

This consists of various improvements upon a previous patent granted to the present patentee and Mr. W. F. Cooke, dated 21st January, 1840. For the details, which are very voluminous, the specification must be consulted. *Patent completed.*

1242. R. ROBERTS and W. SHAW. *Certain improvements in looms for weaving.* Dated June 2, 1858.

This consists in machinery for raising and depressing the healds to form the shed; and in a mode of closing the perforations of jacquard cards or chains. These improvements are not described apart from the drawings. *Patent completed.*

1243. J. E. F. LUEDEKE. *Improvements in motive power engines.* Dated June 2, 1858.

This relates to engines which act by the ascent and descent of collapsible air vessels in water, mounted on one axis. The axis is supported on the lower end of a rod depending from an oscillating beam, while the other end of such beam is connected to a crank and flywheel shaft, by which the reciprocating motion is converted into rotary motion. *Patent abandoned.*

1244. J. MEIKLEJOHN. *Improvements in boilers for heating water, and in valves for controlling and regulating the flow or passage of the same.* Dated June 3, 1858.

This boiler consists of four tubular water spaces, united by a web of a cruciform figure; two of the spaces are arranged in one plane, and two above. From each of the lower pipes a thin web or water-way springs in a diagonal direction, and these meet each other above the plane of the pipes; from this point the web diverges, and is bounded by the two upper horizontal pipes. The upper pipes are closed at both ends, but at the front part of the boiler are united by an arch pipe, in which are two sockets to receive the ends of the outlet water pipes. The boiler is set in the brickwork, with the two lower pipes resting upon the inner walls, the diagonal cruciform web extending upwards, its lower face being directly over the fire, and the union pipe of the upper water-ways being directly under the crown of the brickwork. The result is extended heating surface. These boilers are adapted for horticultural purposes. The valves have a vertical valve chamber, which also serves as an expansion box; in this chamber is a ring of metal, the face forming the valve seating. The valve is simply a disc of brass which rests upon the seating, the two faces being ground together. *Patent completed.*

1245. E. OWEN. *Improvements in water closets, night commodes, or similar conveniences, and also in disinfecting processes.* Dated June 3, 1858.

The patentee applies drawers with double perforated bottoms, and causes them to slide under or over the seat. The sliding is produced by the movement of the lid, or by opening the door. Into the drawers he puts Smith and M'Dougall's disinfecting powder, &c., and by the sliding motion the perforations are opened, through which the powder falls. *Patent completed.*

1246. W. CLAYTON and J. GOODFELLOW. *A certain improvement in pistons for pumps.* Dated June 3, 1858.

This consists in extending the depth of the piston packing so that it projects or stands above the piston cover, the upper edge being bevelled inwards to prevent the lodgment of sand, &c. *Patent completed.*

1247. J. BETHELL. *Improvements in the manufacture of alum.* Dated June 3, 1858.

The patentee takes weak sulphuric acid and puts it in a closed tank, and causes the gas from coal, &c., to pass through it until it is saturated with ammonia, and the liquid becomes liquid sulphate of ammonia; he then takes this liquid sulphate of ammonia and adds it to a solution of sulphate of alumina, and proceeds to make alum by evaporation and crystallisation as usual. *Patent completed.*

1248. T. SCHOLEFIELD. *Improvements in gas meters.* Dated June 3, 1858.

These relate particularly to the ordinary consumers' meters, and consist, 1, in the suppression of the division plate, which separates the drum from the rest of the meter; or in having either the regulating valve and bent arm or siphon pipe covered with a bell dipping into the water in the meter, or in causing the gas to arrive at once into the siphon pipe. 2, in a special form given to the outside casing of the meter. 3, keeping the water in the measuring chamber at a constant level by a scoop forming one arm of a bell-crank lever, the short arm of which lever is slotted, and in which slot works the pin of a crank fixed on the drum shaft; by this means the scoop at each revolution of the drum carries up a quantity of water from a reservoir to the measuring chamber, and the parts submitted to friction are constantly working in the water. 4, in giving to the entrance of the pipe by which the water is introduced in the meter a funnel-shaped form, and in a better disposition of the plug for closing the same. 5, in a box with a proper division plate, situated beneath the end of the bent arm or siphon pipe, a tube or arm of which latter dips into the water with which this box is partly filled, which water may partly be drawn off from the outside of the meter. This box receives the overflow water from the reservoir. *Patent completed.*

1249. A. V. NEWTON. *An improved manufacture of woven fabric, applicable chiefly where strength and durability are required.* (A communication.) Dated June 3, 1858.

This consists in the manufacture of stout textile fabrics, in which all the warp threads are interwoven with the filling threads. *Patent completed.*

1250. G. DALTON. *Improvements in furnaces for smelting the ores of iron and other minerals.* Dated June 3, 1858.

This furnace will be smaller than those in general use, and the body oblong, narrow at the base. Above the feeding-doors the furnace may be at once contracted to the dimensions of a flue, such flue having an exhausting fan. The inventor places fires on both sides of the furnace, and forces air into the ash-pit by a fan-blower. Between the fires and the base of the furnace is a crucible to receive the iron and slag. At the back of the fireplace is an air-chamber communicating with the fireplace. This chamber is supplied with air from chambers at the sides of the ash-pit. There are many modifications included. *Patent abandoned.*

1251. J. MITCHELL. *Improvements in purifying paraffine.* Dated June 3, 1858.

This consists in treating paraffine with animal or vegetable charcoal. *Patent completed.*

1252. R. OWEN. *Improvements in the manufacture of railway wheel tyres, and in machinery employed therein.* Dated June 3, 1858.

The patentee casts an ingot of steel in a mould, with a core formed partly of loam, clay, or sand, affixed to a piece of sheet iron. After this ingot leaves the mould it is heated in a fire. It is next hammered, after which the opening left by the core, which has become closed by the hammering, is again opened, and the two halves of the tyre forced outward until they attain the form of a hoop, after which the hoop may be hammered and then rolled. The patentee rolls the tyres for railway wheels to an uniform inside and outside diameter, by the simultaneous action of inside and outside rolls. *Patent completed.*

1253. H. EDWARDS. *An improved pipe-stem or tube.* Dated June 3, 1858.

This consists in forming a pipe stem in the form of a cornucopia, with the end intended to be placed in the mouth flattened into the form of a duck's bill. The improved pipe-stem was mentioned with approbation at p. 74 of our last Number. *Patent completed.*

1254. T. WILSON. *Improvements in the construction of mangles.* Dated June 3, 1853.

This invention is not described apart from the drawings. *Patent completed.*

1255. J. BARON VON LIEBIG. *Improvements in protecting the silvered surface of mirrors and other articles of glass.* Dated June 3, 1858.

This consists in preparing the silvered surface of mirrors, &c., by depositing thereon a coating of copper, gold, or other metal, by electricity, combined with the use of a neutral solution of the double salt tartrate of the oxide of copper, and soda, potash, or ammonia, or an alkaline solution of gold, nickel, &c. *Patent completed.*

1256. W. HARGREAVES and E. HALEY. *Improvements in machinery or apparatus for preparing and combing wool, hair, silk, cotton, flax, and other fibrous substances.* Dated June 4, 1858.

This consists, 1, in taking the noils, shorts, locks, and dirt, from the wool, &c., while in the gills and fallers, by a card or comb passing through the substance projecting from the gills before drawing it. The inventors then draw a clean tuft of wool, &c., from the gills. 2, in working gills or fallers by four or eight chains instead of screws. *Patent abandoned.*

1257. E. M. STOEHR. *Certain improvements in looms for weaving.* (A communication.) Dated June 4, 1858.

This refers to changing the position of the shuttle-box, so as to bring any of the shuttles in a line with the shuttle-race. A pinion on the crank shaft is used to drive a pair of wheels, each of which has a stud for giving motion to a tappet plate which acts on a lever connected to the shuttle-box. To regulate the position of this tappet plate, a chain of perforated and plain links is used. *Patent abandoned.*

1258. J. F. DICKSON. *Improvements in the permanent way of railways.* Dated June 4, 1858.

This relates to railroads in which the sleepers, wings, &c., are laid longitudinally. The patentee forms the sleepers, &c., of one piece of plate iron, about one-third of an inch in thickness, in which is a groove running its entire length, into which he places the vertical limb of a single-headed rail. He uses a new form of iron sleeper, to be used with the rails in ordinary use. He also forms teeth in the ends of the bolts, screws, &c., and places catches on the nuts, &c., so that the catch may fit the teeth and prevent the bolt or screw becoming loose. *Patent completed.*

1259. V. MERIGHI. *Means of preventing dust on railroads.* Dated June 4, 1858.

This consists in providing a train with water, to be distributed over the track to keep the earth moistened. The capacity of the reservoir of the tender may be increased, or a special tender made use of. To cool the air, frames provided with linen, wire-cloth, or felt, may be applied to the train, to allow the water to run down along, and the air to pass through them, causing an evaporation of the water and a cooling of the air. *Patent abandoned.*

1260. V. MERIGHI. *Means for impeding and extinguishing fires in railway trains.* Dated June 4, 1858.

The inventor provides the water-reservoir of the tender with a force-pump, to carry the water by a hose to any part of the train. *Patent abandoned.*

1261. T. and J. T. CRICK. *Improvements in the manufacture of boots, shoes, and slippers.* Dated June 4, 1858.

This consists in making lasts so that, when an upper is fixed thereon, the straining may be performed by expanding the last, and then that the shoe, boot, &c., may be finished on such last in the usual way. *Patent completed.*

1262. R. QUIN. *Improvements in ordnance and fire-arms.* Dated June 24, 1858.

Here the inventor forms a horizontal and rectangular opening through the breech, perpendicular to its axis, for receiving two moveable chambers, formed in one piece. Between the chambers is a space to facilitate the sponging after firing through an opening in the breech end. To facilitate the ramming of the charges into the chambers, a semi-circular trough is fixed on each side of the piece to act as a guide, both to direct the cartridges into the chambers, and also to guide the rammer in its strokes. The rammer is of a hooked form, so that the gunner while using it stands behind the piece. The moveable breech-piece is formed to an arc of a circle, and at its end radial arms are fixed which proceed to a centre under the piece of ordnance. In constructing fire-arms he makes a passage through the breech of the barrel, as already described, but only a single moveable chamber is employed. *Patent abandoned.*

1263. R. A. BROOMAN. *Improvements in preparing the fibrous portions of certain textile plants, and the employment thereof when prepared, either alone or in combination with articles already in use, for the purposes of stuffing.* (A communication.) Dated June 4, 1858.

This consists in preparing the fibrous portions of the "musa," the "alve," the agave," the "corchorus fuscus," the "corchorus junceus," the "corchorus olitorius," the "corchorus capsularis," and the palm leaf, for stuffing mattrasses, sofas, chairs, &c. The fibres are cut into lengths of about one foot to eighteen inches; the inventor then cards such material in a carding engine, and bleaches the fibres by a chlorine bath of 3 deg. to 4 deg. Beaumé, with a small addition of muriatic acid, he then washes them in clear water with a few drops of sulphuric acid. The fibres when dry are again carded or curled similar to horsehair. *Patent abandoned.*

1264. J. H. JOHNSON. *Improvements in railway wheels, and in axle-boxes and bearings for the same.* (A communication.) Dated June 4, 1858.

A complete specification of this invention was filed with the application, and an abridgement of it was published at page 620, No. 1846 of the MECHANICS' MAGAZINE. *Patent completed.*

1265. J. BANKS. *An improved reaping machine.* Dated June 5, 1858.

This consists of two horizontal discs with cutting edges, and secured to the lower ends of parallel vertical driving shafts mounted on the front of a carriage, one of the discs being so placed as to overlap a portion of the edge of the other. The two upright shafts with their discs are caused to revolve in an opposite direction. Motion is imparted to the travelling wheels by endless bands. The propelling power consists of two horses, yoked side by side at the rear of the machine. *Patent abandoned.*

1266. M. PAGE. *A steam or power kneading apparatus.* Dated June 5, 1858.

This consists in introducing in a horizontal cylinder the materials to be mixed, and in imparting a helical motion to blades fixed at the end of the shaft which rotates in this cylinder. The shaft is supported on bearings so that it can also slide lengthways, as it has a reciprocating motion. *Patent abandoned.*

1267. H. CARTER. *Improvements in gas burners.* Dated June 5, 1858.

The inventor makes the burner of two parts, both having jets, the upper one being formed as usual, and the lower one having smaller holes. *Patent abandoned.*

Digitized by Google

1268. C. HANCOCK. *Improvements in the manufacture of electric telegraph cables.* Dated June 5, 1858.

This consists in protecting the insulated wire by encircling it in a rope of horse hair. *Patent completed.*

1269. E. COOKE and G. DICKINSON. *Improvements in the manufacture of metallic and other bedsteads, and other articles for sitting, lying, and reclining upon.* Dated June 5, 1858.

The specification of this invention is mainly a description of the drawings. *Patent completed.*

1270. R. ORR. *Improved apparatus to be applied to various machines, and is the manufacture of yarn or thread.* Dated June 5, 1858.

This relates to apparatus for rendering uniform the effect of the drag, by which the yarn, &c., is wound upon the bobbing in throstles and doubling frames. A comparatively slow and duly proportioned motion, or a gradually increasing pressure, is imparted by the machine itself to a bar so connected with the frictional appliance as to gradually increase their resisting action. The apparatus is susceptible of various modifications. *Patent completed.*

1271. A. MANBRE. *An improved method of preparing malt and other grain, and of extracting the saccharine matter therefrom, whether for the purposes of brewing, distilling, or otherwise.* Dated June 5, 1858.

Instead of using the grain bruised, the patentee separates the bran by grinding, and uses only the flour. The patentee places in a vessel water, which is heated gradually from 50 deg. to 100 deg. Fah., flour is poured in, and the heating continued to 185 deg. Fah., stirring being maintained the whole time; then is added a quantity of hops, if beer or ale is to be produced; the whole is allowed to settle when infusion and maceration only are required. There are modifications included. *Patent completed.*

1272. F. H WHITEMAN. *Rendering paper hangings, for decorating the interior of houses, capable of being washed by soap and water without detriment to the colours thereof.* Dated June 5, 1858.

The inventor dissolves an ounce of borax and one ounce of stick lac, or other lac, in water, twelve ounces in weight by heat, and strains the mixture. He applies the mixtare with a brush. *Patent abandoned.*

1273. W. PORTER. *Improvements in artillery ordnance, and some other descriptions of fire-arms.* Dated June 5, 1858.

The inventor fixes a rod within the gun, extending along the centre of its bore from the breach to the muzzle. This rod is fixed to the centre of the breach within the gun, and is angular or oval, or has longitudinal grooves upon its exterior; and he gives to the rod a spiral form, or causes such grooves to be made spirally along the exterior of the rod for imparting rotary motion to a projectile. *Patent abandoned.*

1274. W. HOOPER. *Improvements in the manufacture of projectiles.* Dated June 5, 1858.

This consists in the use of the hard compounds produced by subjecting india-rubber and sulphur to heat, in combination with metallic salts. *Patent abandoned.*

1275. G. HADFIELD. *Improvements in the protection of carboys, or other vessels and packages.* Dated June 5, 1858.

This consists in the use of a partial or complete outer casing for increasing the strength of the vessel, rendering it less liable to injury, and better able to resist internal pressure. It also consists in protecting packages by cases constructed of parts capable of being readily separated. *Patent completed.*

1276. E. SCOTSON and H. CHANLEY. *Improvements in machinery connected with traction and other engines, and in endless railways to be used therewith.* Dated June 7, 1858.

This consists in enabling the direction of the revolution of the locomotive wheels to be reversed without stopping or reversing the engine, and also to cause one wheel to turn in one direction whilst the other wheel turns in the opposite direction, so as to turn the engine in a very small space. It also consists in an arrangement of mechanism, forming an endless railway to be used with such engines. One of the advantages of this arrangement is, that by merely opening one of the links of the chain the whole of the railway apparatus may be removed from the wheel. Reference to the drawings is essential to a lucid description of this invention. *Patent abandoned.*

1277. J. FERRABEE. *Improvements in machinery for cutting, collecting, and spreading grass, and for sweeping.* Dated June 7, 1858.

These relate, 1, to the construction and arrangement of the cutting parts of mowing machines, and in the means of regulating their action. 2, to improvements in revolving brushes and rakes, and the use of the same in the manufacture of hay-making and sweeping machines. The invention is not described apart from the drawings. *Patent completed.*

1278. J. J. ROWLEY. *Improvements in apparatus for applying lime, soot, and other matters to turnips and other crops, and manure to land.* Dated June 7, 1858.

This consists in combining blowing apparatus with apparatus similar to what has heretofore been used for applying manure by drills. *Patent completed.*

1279. J. BOULLENGER and L. J. MARTIN. *An apparatus serving to the decomposing neutral fatty substances into fatty or oily acid and glycerine.* Dated June 7, 1858.

The inventors decompose fatty substances in closed vessels by the sole agency of heat, and in certain cases adds acidulated water to facilitate reaction. The substances are afterwards submitted to pressure in a hot or cold state, and then to distillation at a low temperature. *Patent abandoned.*

1280. J. M. DUNLOP. *Improvements in apparatus for sizing fibrous materials.* Dated June 7, 1858.

This consists in using squeezing rollers in sizing machines, or dressing frames covered with vulcanised india-rubber. *Patent completed.*

1281. H. WIMBALL. *Improvements in machinery or apparatus for destroying the turnip fly and other destructive insects on growing crops.* Dated June 7, 1858.

This consists in the use of a fire, carried by a grating supported in running wheels. The fire is supplied with a blast of air from a fan blower, worked by one of the running wheels of the implement, which blast is directed downwards to blow the smoke on to the leaves of the plants. Sulphur, &c., may be supplied to the burning fuel from a hopper worked by the wheels of the implement. *Patent completed.*

1282. E. VIGERS. *Improvements in the manufacture of bricks and other articles moulded or formed from clays.* Dated June 7, 1858.

This consists in applying for the above purposes a material obtained from a refuse article resulting from the use of the torbane mineral, &c., in the manufacture of carburetted hydrogen gas. This refuse is burnt in heaps in the open air, and the result is white masses or nodules which are reduced to powder, and mixed with various kinds of clays. *Patent completed.*

1283. J. B. A. LOMBARD and X. T. ESQUIRON. *A new or improved method of obtaining saccharine substances from cereal and vegetable matters, and applying the products obtained to various useful purposes.* Dated June 7, 1858.

This invention comprises many different features, for the details of which the specification must be consulted. *Patent completed.*

1284. R. HICKS. *The manufacture of a composition or compositions to be employed as black lead.* Dated June 7, 1858.

This consists in forming a composition of black schist, carburet of iron, combined with "shining" or "shiny" ore, and plumbago of commerce, and with or without soda and lamp black. There are various modifications included. *Patent completed.*

1285. J. M. DUNLOP. *Improvements in bowls or rollers used in machines for printing fibrous materials.* Dated June 8, 1858.

This consists in covering the bowls or rollers with vulcanised india-rubber, &c. *Patent completed.*

1286. R. WAPPENSTEIN. *Improvements in the manufacture of artificial whalebone, applicable to umbrellas, parasols, stays, hats, bonnets, reeds, crinolines, and other similar purposes.* Dated June 8, 1858.

This consists in cutting the horns of animals spirally to any breadth or dimensions. The spiral so cut is then untwisted and flattened by pressure. *Patent completed.*

1287. I. KETCHUM. *An improved self-acting perforated buster.* Dated June 8, 1858.

A vessel, the bottom or sides of which are perforated, is fixed above the joint of meat, &c., and being filled with fat it will pass through the perforations and drop upon the joint of meat, &c. *Patent abandoned.*

1288. J. C. QUINCE. *Improvements in stoppers for bottles and jars.* Dated June 8, 1858.

This stopper is formed in the interior with a groove fitting over the top of the bottle or jar, with a plug fitting into the mouth of the same. A washer of leather, &c., is inserted in the groove, and fills up the space between the substance of the stopper and the top of the bottle or jar. The exterior of the stopper is grooved to receive a wire for attaching it to the neck of the bottle or jar. *Patent completed.*

1289. R. A. BROOMAN. *Improvements in the manufacture of copper pipes and tubes.* (A communication.) Dated June 8, 1858.

This consists in making copper tubes and pipes without joint or weld, and either straight or curved, by depositing copper in a galvanic battery over and upon a core of lead, &c., which can be reduced or removed by heat. *Patent abandoned.*

1290. W. CLARK. *The manufacture or preparation of extract of Peruvian guano.* (A communication.) Dated June 8, 1858.

This consists in submitting the above guano to a series of boilings in certain quantities of water. *Patent completed.*

1291. A. ROBERTSON. *Improvements in stoves or fire-grates.* Dated June 8, 1858.

Here the inner or lower top plate is made in one piece. The lower edges are made to rest on horizontal or curved mouldings at the spring of the arch, or behind the inside check. This inner top plate is hinged at the upper part to the fixed arched top plate, so that it may be thrown up out of the way of the smoke. *Patent completed.*

1 92. J. BUNNETT. *Improvements in the construction of floors, roofs, and arches.* Dated June 8, 1858.

Here earthenware or clay blocks are used with tie rods and wall plates, so that the thrust is brought in each case to act on the tie rods and the wall plates, the several blocks being so formed as to over and underlap each other. The wall plates are made of angle iron, and are tied together by the tie rods at intervals. The tie rods should pass through the blocks, such blocks being made hollow with that view, as well as to obtain lightness. The two sides of each block are each composed of two parallel inclines, each about half the depth of the block, connected by a horizontal, or nearly horizontal plane, and the two inclines on the one side are parallel with those on the opposite side. *Patent completed.*

1293. D. IRONS. *Improvements in the mariners' compass.* Dated June 8, 1858.

This consists in so constructing a compass that its needle shall at all times front due north and south. The card of a compass has three magnates or needles. One needle is of the ordinary kind, and fixed on the card to point north and south; the other two are fixed to the card at right angles to the other needle. The north end or pole of one of the two additional magnets is outwards, and placed to the west of the north end or pole of the first-mentioned magnet or needle. The third magnet has its south pole outwards, and in position it corresponds with the east front on the card. *Patent completed.*

1294. J. RAWLINGS. *Improvements in thrashing machines.* Dated June 8, 1858.

The principal object here is to obtain a mechanism to be worked by hand labour. The thrashing drum and apparatus connected therewith are arranged as in thrashing machines worked by horse or steam power. The axis of the drum receives motion in the following manner:—A shaft turns in bearings at right angles to the axis of the drum. On the outer end of such shaft is applied a crank handle, and on the other end is fixed a bevelled toothed wheel, which takes into and drives a like wheel on an axis parallel with that of the thrashing drum. On this axis is a drum, which gives motion by a strap to the drum on the fly-wheel, on which there is a drum which by a strap gives motion to a drum fixed on the axis of the thrashing drum. A crank handle may be fixed to the axis which is parallel with the axis of the drum. *Patent completed.*

1295. A. RIGG, sen., and A. RIGG, jun. *Improvements in apparatus for tipping or upsetting coals, minerals, or other substances, and in brake machinery.* Dated June 8, 1858.

This apparatus consists of a framing mounted on axles, on which framing the waggon, &c., is held firmly. On the axle there is a brake wheel, surrounded by a band, which is connected to a lever, which moves between fixed guides, on which guides there are ratchet teeth, into which a click on the lever takes, so that the brake can be left in any position on the brake-wheel. There are also teeth into which a click enters, so that, after the coals, &c., have been upset, the moveable parts are prevented from returning until the click is released. The waggon, &c., is placed on the framing, so that the centre of gravity is beyond the axles, so that, when the brake is released, the framing and waggon tilt over, and the speed at which they are allowed to tilt is regulated by the brake. The framing is so weighted that, when all the coal, &c., has been upset, and the click released from the teeth on the brake-wheel, the framing resumes its first position. To the front of the framing is fixed a scoop or screen, which receives and guides the coal, &c., as it slides or falls to the spot required. *Patent completed.*

1296. G. SNARES. *An improvement in fire-arms.* (A communication.) Dated June 9, 1858.

This is for constructing fire-arms, so that they may fire "eighteen or more" shots in succession in an extremely short time, the arrangements admitting of great facility in the handling and loading. They consist of a tube at the top of the barrel for containing the projectiles and conducting them to a chamber, which may be a continuation of the connecting-tube; from this chamber, the charge is placed in the breech of the barrel, and discharged in rapid succession by suitable arrangements for the purpose. *Patent abandoned.*

1297. F. A. GATTY. *Improvements in dyeing cotton and other fibrous materials and fabrics.* Dated June 9, 1858.

This invention consists in applying for dyeing purposes the colouring matter contained in the clearing liquors of dyers and printers (especially those of Turkey red dyers), in which cotton or other fibrous material or fabric previously dyed with any preparation of madder has been washed or cleared. *Patent completed.*

1298. D. MOSELEY. *Improvements in machinery used in the manufacture of vulcanised india-rubber thread.* Dated June 9, 1858.

In manufacturing vulcanised india-rubber thread it is usual to lap a sheet of rubber around a roller, this sheet passing through a trough containing a solution of shellac, which causes the whole to adhere while being cut. In the usual mode of operation the sheet passes under a rod or roller placed in the trough, and the surplus shellac is removed by an instrument called a "doctor." This invention consists in dispensing with this instrument, and in causing the large roller on which the vulcanised india-rubber is lapped to bear on the roller in the trough containing the solution of shellac, and around which the sheet of india-rubber passes before it is lapped on the large roller. When the vulcanised india-rubber is being wound on the large roller the surplus quantity of shellac or other cement is squeezed out by the pressure between the lap and the roller in the trough. *Patent completed.*

PATENT-LAW REFORM.

BEFORE noticing the petition which the Manchester men resolved last week to send to Parliament, it will be well to mention a consideration or two which but few persons seem to regard, but which have an important bearing upon the subject of Patent-Law Reform.

There is, first, the fact that the proprietors of valid patents are a privileged class—privileged, because they are put into possession of exclusive rights which would not be their's but for the Patent Laws. This fact is by far too often forgotten or suppressed by those who speak and write on the question before us. Even Mr. FAIRBAIRN, in his speech of last week, stigmatizes the fees payable on patents as a "tax" upon the "genius" of the inventor. But they are nothing of the kind. The inventor by his "genius" can produce nothing but ideas, upon which no Government can lay a tax. The fees become payable only when the inventor seeks to acquire an exclusive property for a term of years in some machine or some process the idea of which he has (we will presume) been the first to conceive, but which another man may conceive to-morrow. If this be denied by anyone, let him imagine the Patent Laws abolished, and the "tax on genius" therefore repealed, and then ask himself whether the inventor has benefited by the change. The truth is, that by granting the existing privileges to patentees, the Government confer upon them advantages for which they may very fairly be expected to make some return; and as those advantages are of a pecuniary character, fees are a return of a very suitable kind. It was doubtless in view of these considerations that, when the recent Patent Acts were formed, provision was made for appropriating the £5 payable on the "warrant," and £10 of the £50 payable on the extension of the patent, to a surplus fund which should go to the revenue of the nation, and which has amounted to about £90,000 since 1852.

But while the raising of revenue from patent fees is thus shown to be perfectly equitable, few persons now believe it to be politic. It is very properly thought that the arts, and sciences, and manufactures of the nation would be more rapidly improved if all attempts to draw revenue from this source were abandoned; and we doubt not that the present Commissioners of Patents—including Lord Chancellor CHELMSFORD, Sir FITZROY KELLY, and Sir HUGH CAIRNS, who are enlightened men, and anxiously solicitous, we believe, to promote the best interests of the country—will cheerfully recommend their abandonment, and be willing to reduce the fees on patents, till they are sufficient only to meet the expenses of the Patent Office. If they will do this, they will be enabled to abolish altogether the £100 payments which, otherwise, will shortly become due on patents of the seventh year, and at the same time to reduce or defer the £50 payment on patents of the third year, and some of the earlier fees likewise. We would not, like the Manchester Association, prescribe precise fees to the Government; nor do we think it probable that the scale which the Association has adopted would be found sufficient for all legitimate expenses of the office. They propose—

"That the present stamp duties on patents be reduced to the following scale, namely, £5 on application for protection, £10 for warrant and seal, and £25 at the expiration of five years; and that the stamp duty of £100, now payable at the expiration of the seventh year, be entirely abolished."

They also recommend—

"That the surplus funds, if any, arising from the said scale of charges shall be set apart and considered as a fund appropriated to the carrying out the acts relating to patents for inventions, with the view of promoting the progress of invention and science."

Should these proposals be adopted, the fees on the early stages of a patent would be reduced from £25 to £15, and the whole fees on a patent for fourteen years would be brought down from £175 to £40. We doubt whether reductions to this extent will be found practicable; but whether the Government are able to go the full length of our desires or not, we have great reason to require that a very large diminution of fees shall be made, and with as little delay as possible.

Another reform which we expect the Government to undertake at once is that of providing a suitable building for the Patent Office. Mr. DISRAELI has, we find, adroitly disposed of the long-standing National Gallery difficulty; and why should he not join the Patent Commissioners in settling their's? Inventors, patentees, and men of science everywhere, want to see that splendid Patent Office library disentombed—brought forth from the vaulted passages and dark corners in which it is now heaped, and placed conveniently at their service. The present state of that library is so bad that the place is all but useless to the public, and it had better be shut up altogether than kept as it now is. No man can there enter upon any of those researches for which such libraries are mainly useful, without annoying every one besides himself—indeed, one cannot enter upon any considerable researches whatever in that gloomy and crowded cavern! There is not a library or a reading-room, or a news'-room, or even a boy's schoolroom in the kingdom where there is less accommodation than in the library of the Great Seal Patent Office of England; which should be, and with additional space only would be, the first scientific library in Europe! And as for the Patent Museum, with its original models of WATT'S and SYMINGTON'S earliest engines—its first hydralic press that BRAMAH ever made—its first screw propeller that ever moved a ship of war—its hundreds of examples of modern machinery—and its portrait gallery of men who have made England what it is—this instructive Museum, so valuable for reference, is far away at South Kensington, three or four miles from the library which it illustrates!

It has been rumoured that the Government has proposed, and the Commissioners of Patents agreed to, the erection of a Patent Office in the grounds of Burlington-house, it being at the same time intended to keep the museum where it now is. We cannot credit such a rumour. Everyone knows that Sir RICHARD BETHELL and other eminent lawyers are exerting themselves to get the law courts concentrated, and that the sight coveted for the combined courts is in the neighbourhood of Chancery-lane. It cannot surely be possible that while these efforts are being made, such men as the present law officers can assent to the removal of the Patent Office to Piccadilly, when every individual connected in any way with it must earnestly desire that it may remain near its present position. How are inventors, patent agents, barristers, and others to transact daily business in an office two miles from the City? And we may ask with equal wonder, how are the Lord Chancellor and the Attorney and Solicitor General—whose communications with the Great Seal Patent Office are frequent and often most urgent—to perform their duties in connection with an office thus situated? We can conceive of no satisfactory replies to these questions, and we therefore discredit the rumour. We have confidence in the present Commissioners, and believe that they will take the necessary steps to give us a large commodious edifice, combining museum, library, and business offices, in Chancery-lane or near it. There is a vacant piece of ground on the upper side of Carey-street, which, though small at present, might probably be increased rapidly by purchase, and this would form an admirable and convenient site for such a structure. We would assure the Commissioners of Patents that their action in this matter will be watched with anxiety by many, and we sincerely hope they will be true to the trust which is reposed in them.

In the Manchester petition there are two clauses which we do not fully understand. They are as follows:—

"That additional or special commissioners be appointed possessing scientific attainments as contemplated and provided for by the first section of the Patent Law Amendment Act of 1852, to assist the law officers of the Crown in passing patents.

"That such special commissioners be required to report to your honourable House from time to time on the working of the Patent Law, and to suggest such alterations and amendments as may appear expedient."

If the petitioners intend by these clauses to imply that the law officers pass patents too readily, and do not refuse them sufficiently often, and that, with the aid of special Commissioners, they would pass them less readily, and refuse them oftener, they are advocating a very questionable policy, and one which inventors would not easily brook. Much money is doubtless wasted by infatuated men in patenting old inventions, but it is much better to allow such individuals to squander a few pounds than it would be to subject every man's invention to the mutilating action of a set of Commissioners who are practically irresponsible, as is done in America. This part of the petition at least needs explanation.

With the spirit of the next clause we heartily concur. It is—

"That a special court be appointed to try patent cases and that scientific persons conversant with the subject before the court be summoned as jurors, and paid for their services out of the surplus fund, and that their decision shall be final."

Under the present system of trying patent cases, an immense amount of expense is often incurred by both plaintiff and defendant with no satisfactory or just result. The preceding clause is intended to remove this evil. The only doubt we have is, whether "scientific persons," who are notorious for disagreeing when they appear as witnesses, would be got to agree as jurors. We fear they would often spend supperless nights, and be as often disbanded without accomplishing any result. Still, in a modified form, a special court and special jurors would doubtless dispense readier and more even justice than the courts and juries that now settle patent disputes. We could hardly expect to read then of judges sitting day after day over a single case, as Mr. Justice ERLE has been sitting this week, in the Second Court of Queen's Bench, over "Betts *v.* Menzies."

The two recommendations with which the Manchester petition concludes must meet with the approbation of all honest and economical men. They are—

"That a penalty be imposed on all persons selling goods as patented articles which are not patented.

"That some simple means be devised to secure patents for her Majesty's colonies."

We recommend our fellow Patent-Law re-

Digitized by Google

formers to keep their eye steadily on the three points of prime importance to inventors—viz., the reduction of the fees, the provision of a suitable library, and the ready settlement of law cases—and to labour steadily and strenuously for the accomplishment of these objects. They should carefully guard themselves against encumbering these with minor questions, and also against urging them in an ill-digested form, or with too little consideration.

THE CASE OF HENRY CORT, AND HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

BY

THOMAS WEBSTER, M.A., F.R.S., &c., Barrister-at-Law.

No. II.

THE inventions of HENRY CORT constituted one of the epochs in the history of the manufacture of iron in Great Britain. Before, however, entering on the details of CORT's inventions, it will be necessary to consider the state of the manufacture of iron prior to the middle of the last century, and the various attempts previously made to render Great Britain less dependent on foreign countries for the supply of so important an article of commerce.

The earlier history of the manufacture of iron in Great Britain, and the attempts to prohibit the consumption of wood, and to encourage the substitution of pit-coal for wood or charcoal in the smelting of iron, are matters of curiosity; showing, however, conclusively how severely the scarcity of fuel was felt, and how great was the inducement from the necessary abandonment and suspension of iron-works in Sussex and other parts—then the natural seat of the British iron manufactures—to look to foreign countries for the supply of the deficiency in that material. During the 14th and 15th centuries, iron was imported from Germany, Prussia, Spain, and other parts beyond the seas. In the 16th century, the Germans established works in this country, in the Forest of Dean and near Tintern, introducing at the same time the manufacture of iron-wire; and although the information as to the number of works in this country up to the middle of the 16th century is very scanty, there can be no doubt that the works had materially increased in many parts of the country, particularly in Sussex; and that, but for the alarm as to the scarcity of wood, and the prohibition or restrictions imposed on its use, Great Britain was in a fair way of becoming independent of foreign supply. We learn from LELAND and CAMDEN that the Forest of Dean and Sussex in particular abounded in iron, and mines, and forges, in the early part of the 16th century, but in 1558 an act (1 El. c. 15) was passed, prohibiting the conversion of any timber of certain dimensions growing within fourteen miles of the sea, or any part of the Thames, Severn, or other river, into coal for the making of iron, except Sussex, and certain parts of Kent and Surrey; in 1581 another act (23 El. c. 5) was passed to prevent the destruction of timber and to prohibit the erection of iron-works within a certain distance of London, the Thames, and in certain parts of Sussex, and the conversion within the same limits of wood into coal or other fuel for making iron, which prohibition was extended, by a subsequent act (27 El. c. 19), to the erection of any new iron-works in Surrey, Kent, or Sussex, and the using of any timber of one foot square at the stub as fuel at any iron-works was forbidden. From the operation of these and other causes, the iron-works in many parts of country were either stopped entirely, or their make materially diminished, and the country had to rely more and more on the supply of iron from foreign parts.

The necessity of some other source of supply of iron than that smelted and manufactured by the use of wood or charcoal, turned the inventive minds of the country to the practicability of applying other fuel, as pit-coal and peat, in the smelting or melting of iron, and attempts were made by many persons about the middle of the 16th century with this object, but without, as it would appear, much practical success until nearly the middle of the next century.

The patents, and similar royal grants in connection with this subject, afford instructive illustrations of the legitimate exercise of the royal prerogative for the advancement of manufactures and the reward of the inventor. The express reservation in the Statute of Monopolies (21 Jac. 1) of the letters patent granted (22nd February, 19 Jac. 1) to EDWARD LORD DUDLEY, for the melting of iron ewer (ore) and of making the same into cast works or bars with sea-coals or pit-coals, must also be regarded as a judgment of Parliament in favour of a grant, having such a legitimate and useful object, at a time when, from the abuse of the exercise of the royal prerogative, all grants of monopolies were looked upon with such suspicion that King JAMES, by "a declaration of His Majesty's pleasure," (A.D. 1610), published and declared, out of His Majesty's zeal to law and justice, that monopolies are things against the laws of the realm, and expressly commands that no suitor presume to move the King to grant any of them. The monopolies therein referred to were such as had been obtained from Queen ELIZABETH for twelve years (13 June, 30 El.,) and for 21 years (11 Aug, 40 El.), respectively, of the exclusive privilege of buying playing-cards beyond the seas, and making and selling the same within Her Majesty's dominions; or by EDWARD III. to JOHN PEACHEY, for the sole importation of sweet wines to London, which was declared against the freedom of trade and traffic, and to be illegal and void, in respect both of its nature and duration; but no doubt was ever entertained as to the legality or policy of grants for a limited duration for a new trade or manufacture within the realm which others at the time of making such grant did not use, as was stated in the earliest case on the subject in the following terms:—

"Now, therefore, I will show you how the Judges have heretofore allowed of monopoly patents; which is, that where any man, by his own charge and industry, or by his own wit or invention, doth bring any new trade into the realm, or any engine tending to the furtherance of a trade that never was used before, and that for the good of the realm, that in such cases the King may grant to him a monopoly patent, for some reasonable time, until the subjects may learn the same, in consideration of the good that he doth bring by his invention to the commonwealth, otherwise not."

The earliest grant connected with this subject was for 31 years, by King JAMES in 1612, to SIMON STURTEVANT for the manufacture of iron with pit-coal in all its branches, made subject to the condition of his publishing an account of his discoveries, which condition he complied with by the publication of his "Metallica." It would appear that he failed in his attempts, for he was compelled to surrender his grant in the following year, and we find another grant for the same object to JOHN ROVINSON, also upon the condition of his publishing an account of his discoveries, which condition he also complied with by the publication of his "Metallica," in 1613; but he also with other enterprising men about that time who obtained grants for the same objects, had to resign them, after ineffectual attempts to succeed in the manufacture of iron with pit-coal.

The first patent (granted 19 Jac. 1) to EDWARD LORD DUDLEY for 31 years, would appear to have been cancelled, and another granted in the same year (22nd Feb. 1622, 19 Jac. 1.), which, after reciting as a fact the discovery of "the mystery, art, way, and means of melting of iron ewre (ore), and of making the same into cast works or bars with sea-coals or pit-coals in furnaces with bellows, of as good a condition as hath been heretofore made by charcoal," and further reciting the benefit to result, amongst other things, from the saving of timber and wood wanted for shipping and otherwise, and "holding it agreeable to justice that the authors of so laudable and useful inventions should in some good manner reap the fruits of their studies, labours, and charges," grants the exclusive privilege for fourteen years, within the realm of England and dominion of Wales, to practice the invention of melting iron ore, and of making the same into cast works or bars with sea-coals or pit-coals in furnaces with bellows, and to set up engines for the purpose. This patent was saved by express terms in the Statute of Monopolies. It is somewhat remarkable that this grant should have been only for fourteen years, most of the preceding grants having been for larger terms, as for thirty-one years. It might have been owing to better views as to the most suitable length of the terms of such grants after the declaration made by His Majesty in 1610, or not improbably to the opposition of rival manufacturers, particularly the proprietors of the works engaged in the wooden or charcoal iron trade, who formed a combined and powerful opposition against those engaged in the pit-coal iron manufacture. The following account of the invention, given by DUD DUDLEY, the son of Lord DUDLEY, in the "*Mettallum Martis*," will be read with interest:

"Having former knowledge and delight in iron-works of my father's, when I was but a youth, afterward, at twenty years old, was I fetched from Oxford, then of Baliol College, anno 1619, to look over and manage three iron-works of my father's, one furnace and two forges, in the chase of Pensnet, in Worcestershire; but, wood and charcoal growing very scanty, and pit-coals in great quantities abounding near the furnace, did induce me to alter my furnace, and to attempt, by my new invention, the making of iron with pit-coal, assuring myself, in my invention, the loss to me could not be greater than others, nor so great, although my success should be fruitless; but I found such success at first trial as animated me, for, at my trial or blast, I made iron to profit with pit-coal, and found *facere est adders inventioni*. After I had proved by a second blast and trial the feasibility of making iron with pit-coal and sea-coal, I found, by my new invention, the quality to be good and profitable, but the quantity did not exceed above three tons per week, though I doubted not in future to have advanced my invention to make quantity also.

"Immediately after my second trial I wrote unto my father what I had done, and withal desired him to obtain a patent for it from King James of blessed memory: the answer to which letter I shall insert only to show the forwardness of King James to animate the inventor as he did both Simon Sturtevant, John Rovenson, Dr. Jordanie, and others."

The account of obtaining the patent is described in the following letter:—

"SON DUDLEY,—The King's Majesty being at Newmarket, I sent Parkes thither on Saturday, to some friends of mine, to move the King's Majesty for my patent, which he, coming on Sunday morning, in the afternoon his Majesty sent a warrant to Master Attorney to dispatch my patent, for the which I am infinitely bound unto his Majesty, that it pleased him, of his great grace and favour, to dispatch it so soon. I have been this night with Master Attorney, who will

Digitized by Google

make haste for me. God bless you, and commend me unto all my friends.

"Your loving father,

"EDWARD DUDLEY."

Reading the above account of the successful use of pit-coal in the manufacture of iron with our present knowledge, it may be inferred that the cause of the failure of others, and of the success of DUDLEY, was due to an improved blast. However this may have been, it would appear that the production did not at the first amount to more than three tons per week, or about one-half the yield of furnaces using charcoal.

The historian of the "Metallum Martis" goes on to state that the PARKES referred to in the above letter was the author's brother-in-law, and that he did, about one year after the patent was granted, carry from the author much good merchantable iron into the Tower by King JAMES's command, to be tried by artists who did well approve of the iron, and out of which a fowling-gun was made.

Parliamentary Proceedings.

[CONDENSED FOR THE "MECHANICS' MAGAZINE."]

HOUSE OF COMMONS.

FRIDAY, Feb. 4.

SUPERANNUATION FUND.

The CHANCELLOR of the EXCHEQUER gave notice that on Monday he would bring in a bill to amend the law relating to superannuation allowances.

SALE OF POISONS.

Mr. WALPOLE gave notice that on Tuesday he should introduce a bill to regulate the sale of poisons.

GALWAY HARBOUR.

Lord DUNKELLIN asked the First Lord of the Admiralty whether he had any objection to lay on the table of the house a copy of the instructions given to the commissioners appointed last October, by the Irish government, to inspect Galway, and of the report presented by the commissioners, and to state what steps, if any, her Majesty's government had taken, or propose to take, in consequence thereof.

Sir J. PAKINGTON had no objection to laying the report on the table. The inquiry could not exactly be called a commission. An application having been made to the Lord Lieutenant of Ireland, he appointed Captain Washington and Mr. Veitch, who, in conjunction with Mr. Gibbon, an Irish engineer, examined the harbour. The report was greatly in favour of its capabilities in both particulars, and the commissioners think that an expenditure of 100,000*l.* would make the harbour extremely valuable both as a harbour of refuge and for the packet service. No final steps had been taken by the Treasury.

Mr. H. HERBERT asked whether the inquiry had been limited to Galway.

Sir J. PAKINGTON—The inquiry was so limited.

PUBLIC WORKS (INDIA).

Mr. HADFIELD, with reference to that paragraph in the royal speech which related to India, mentioned the alarm felt in this country lest a deficiency should arise in the supply of their staple materials, particularly cotton, of which India could, under proper management, furnish an abundant supply. What India wanted was roads and water for irrigation.

Lord STANLEY, for the present, would only say that he agreed entirely with the hon. member, both as to the necessity of greatly increasing the cotton supply, and of improving the means of transit. It had been estimated that the difference between a good and a scanty supply of cotton for the country was equal to the difference between an income-tax and none, that was to say, that it was equal to the income-tax in time of war. The government was therefore bound to do everything in their power to promote the growth of cotton in India, as well to facilitate the communication between different parts of that country. Even in the present financial position of India, the expense for public works must not be discontinued. It was a mistake to suppose that little or nothing had been done in furtherance of public works in India. For a considerable number of years two millions annually had been appropriated to the purpose. At present they were in this unfavourable position with respect to the money applicable to public works, that the capital for 5,000 miles of railways had been guaranteed, while not more than 500 miles had yet been completed, or were making any return, but he was confident that when the whole had been completed, the traffic would be so enormous as to make an ample return. He should be prepared ten days hence to enter in detail into the question.

Mr. BRIGHT admitted the necessity for establishing railways and roads in India; but, while in Ireland the roads were probably better than in any part of her Majesty's dominions, they had not assisted much in the development of the resources of the land, because the tenure of land in that country remained in an unsatisfactory state. The same grievance existed in India.

Colonel SYKES said there was no difficulty in obtaining cotton in any quantity in India if it was made worth the while of the producer to produce it. At present India sent to Europe 23 millions of its products, and received back not more than 12 or 13 millions of the manufactures of this and other European countries; because the people of India had no use for our woollen manufactures, glass, and hardware. There were three important public works now going on in India—the screw-pile pier at Madras, the water-works at Bombay, and the improvement of the harbour of Kurrachee—from which great benefits would result.

Sir J. ELPHINSTONE observed that the great difficulty was in getting the cotton down to the coast without injury by the existing modes of conveyance. He suggested that the manufacturers and others in this country who wanted cotton from India should appoint agents to go up the country, purchase the cotton, and superintend its conveyance down to the place of shipment.

MONDAY, Feb. 7.

HARBOURS OF REFUGE.

Mr. WILSON asked the First Lord of the Admiralty whether the Royal Commission appointed in pursuance of a vote of this House in the last session, upon the subject of harbours of refuge, had yet made their report, and when the same would be laid upon the table?

Sir J. PAKINGTON said the commissioners had not yet reported.

CIVIL SERVICE SUPERANNUATION.

The CHANCELLOR of the EXCHEQUER, in bringing in a Bill amending the present laws concerning superannuations and other allowances to persons having held civil offices in the public service, said—The measure proposed on this subject is very similar to, or identical with, the Bill of last year.

Mr. WILSON said a great many of the higher class of officers engaged in the dockyards had retired on full salary, but while that had been done many who entered the service at the same time had received superannuation allowances amounting to only one-fourth of their salaries. He knew a case of two men who entered the service on the same day, and who were superannuated on the same day, after having been employed for many years in the same manner, bearing unexceptionable characters, both having received the thanks of the Admiralty. One of these men has been superannuated on an allowance of £740 a-year, and the other of £34 a-year. That arose from the inequality of the law as it now stood. He contended, however, that, as they had abolished the abatements, they could no longer make any distinction between the public servants. He wished to know whether the inequality that now existed was to be maintained, or whether the Bill would be made applicable to all alike.

The CHANCELLOR of the EXCHEQUER said, if the hon. gentleman moved an amendment he should be better able to deal with it than he could now. With regard to the dockyard servants, they were specially provided for by the Admiralty orders, and it was quite unnecessary that they should be included in the Bill.

Mr. KINGLAKE said the Bill of last year gave superannuation allowances to Post-office servants resident in London, but excluded those who lived in the country. The natural result was that much disquiet was caused by the distinction, and he hoped the defect would be remedied in the present measure.

Mr. COLLIER believed the Chancellor of the Exchequer was in error in asserting that the superannuation of dockyard labourers was provided for by certain Admiralty orders.

Sir ERSKINE PERRY concurred in the same view, and recommended that all the servants of the Government should be pensioned upon one uniform scale.

Mr. RICH suggested that it might be well to restore that system of abatements from salaries which was lately abolished.

Sir F. SMITH trusted that the Bill would embody stipulations by which the dockyard labourers would be protected even against the Admiralty, which was sometimes inclined to be niggardly.

The CHANCELLOR of the EXCHEQUER explained that he had referred to the latest copies of the Admiralty orders, which, as they bore a date so recent as October last, had not, perhaps, been seen by hon. gentlemen who had just spoken. [The right hon. gentleman then read from the Admiralty order in question a passage referring to the superannuation allowed to labourers and artificers.] This showed that the labourers in our dockyards were in receipt of regulated rates of pension. Leave was then given to bring in the Bill.

TUESDAY, Feb. 8.

SCHOOL INSPECTORS' REPORTS.

Mr. COWPER gave notice that on Tuesday, the 22nd, he should call the attention of the House to the recent circular of the Committee of Council for Education with reference to the reports of the Inspectors of Schools, when he should move that the efficacy of the inspection of schools depending upon the publicity given to the results, the reports of the inspectors ought to continue to be laid upon the table; and that the tabulated reports of districts ought also to be printed and laid upon the table as heretofore.

THE NATIONAL GALLERY.

Sir H. WILLOUGHBY wished to ask whether a gallery for pictures was being built, and in what locality? Also, what would be the expense of such building, and out of what moneys voted by Parliament the cost would be defrayed?

The CHANCELLOR of the EXCHEQUER in reply, made a statement to the effect that the Government had provided the Royal Academy with part of the ground at Burlington House, and that the Academy was about to erect premises for itself, at its own cost, upon it, giving up the National Gallery entirely. The Vernon Gallery and Turner pictures are ultimately to be placed in the National Gallery, but as the Prince of Wales wants Marlborough House forthwith, they are for the present to be removed to a temporary building about to be erected on the ground rented by the Government from the Royal Commissioners at Kensington Gore. The whole of the arrangements for the final disposal of the various collections of pictures are expected to be completed in about two years.

THE ATLANTIC TELEGRAPH.

Mr. H. BERKELEY asked the Chancellor of the Exchequer if Her Majesty's Government was about to grant a guarantee or subsidy to the Atlantic Telegraph Company; and, if so, upon what conditions.

The CHANCELLOR of the EXCHEQUER said that several applications had been made to the Treasury for a subsidy for the purpose referred to; but no resolution had been come to of the kind mentioned by the hon. gentleman.

SALE OF POISONS.

Mr. WALPOLE brought in, and had read for the first time, a bill for regulating the sale of poisons. Its chief object is not an impossible attempt to prevent murder by poisons, but to prevent accidental injuries resulting from their careless sale. It will control the "keeping" as well as the "sale" of poisonous substances.

SUPPLY.

On the motion of Sir S. NORTHCOTE, the House resolved itself into a Committee of Supply; Mr. Fitzroy in the chair. The paragraph in the Queen's Speech relative to the estimates having been read, a formal resolution was agreed to, "That supply be granted to Her Majesty."

WEDNESDAY, Feb. 9.

SUPPLY.

The report was brought up and agreed to. The committee was ordered to sit on Friday.

On the motion of Sir S. NORTHCOTE, an address to Her Majesty was agreed to, praying that the navy and army estimates for the ensuing year may be laid upon the table.

THE THEORY OF NAVAL ARCHITECTURE.

No. III.

[We hope the following article, which will probably appear repulsive to some of our readers, will not deter them from pursuing the study of this series of papers. They should observe that, although it is highly necessary for us to investigate the nature of the *rules* used by the naval architect, and although the investigation involves processes which persons unskilled in mathematics may deem difficult, yet the rules themselves, and their practical applications, are very simple. As we purpose making our articles as complete as possible, we cannot omit such investigations as the following: at the same time, non-mathematical readers may content themselves with glancing over them, and gathering their general scope and objects, without attempting to follow the arguments throughout. In due time, the humblest reader will find himself led safely and surely through all the theoretical knowledge that it is essentially necessary for a practical designer or builder of ships to acquaint himself with. We may add, for the information of those who are mathematicians, that our investigations of rules are, in the main, original, and conducted without presuming a knowledge of the integral calculus.]

THE next method of approximating to a curvilinear area is, to draw some known curve through the extremities of three consecutive ordinates, and find the area between this curve and the other boundaries of the figure, neglecting, as inappreciable, the very small area between the two curves.

Now a circle, which is a simple curve, may always be drawn through three points, and if the ordinates be not very far apart, the circular arc drawn through the points P_1, P_2, P_3, fig. 8, (p. 57*) for example, would nearly coincide with any given curve; and the area, of which the arc thus drawn is one of the boundaries, would approximate sufficiently near to the required area for all practical purposes. We should then have, as an approximation to the required area, either the two trapeziums, $P_1 P_2 N_2 N_1$, $N_2 P_2 P_3 N_3$, and the two small circular segments, of which $P_1 P_2$ and $P_2 P_3$ are the chords; or the trapezium $P_1 P_3 N_3 N_1$, and the segment of which a line joining $P_1 P_3$ is the chord. It happens, however, that the area of a segment of a circle is found with great difficulty; and

* Throughout the reading of these articles reference must be made to preceding Numbers of the Magazine wherever necessary.

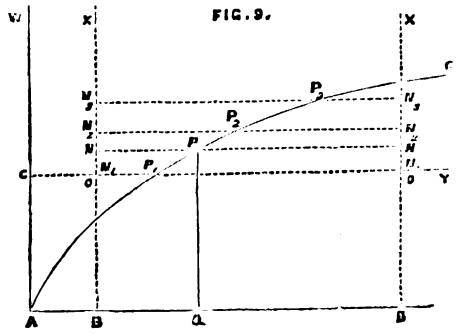
Digitized by Google

although the circle would be very suitable as an approximating curve, it cannot be made use of in this case, where simple calculations are indispensable.

The common or conic parabola is also a simple curve, but in its usual form it is only capable of being drawn through two points. The common form of the equation to the parabola is $y^2 = lx$, in which the origin of co-ordinates is at the vertex A; and l, which is constant in the same parabola, is called its parameter.*

Let P be any point in the parabola, then, fig. 9, $PQ^2 = l \times AQ$.

FIG. 9.



Instead of taking AW, AB as co-ordinate axes, let the dotted lines OX and OY be taken, their intersection O being the new origin. Let

$PN = Y$, $ON = X$, $OC = a$, $OB = b$.

Then $PN = Y = BQ = AQ - AB = x - a$;

or $x = Y + a$.

And $ON = X = PQ - OB = y - b$;

$\therefore y = b + X$.

Substituting these values for x and y in the common equation, we have $(b + X)^2 = l(Y + a)$. Multiplying out, dividing and transposing,

$$Y = \left(\frac{b^2}{l} - a\right) + \frac{2b}{l}X + \frac{X^2}{l},$$

which may be put in the form—

$$Y = A + BX + CX^2,$$

which is the general equation to the common parabola, whether the point O be within or without the curve; that is, whether the curve be concave or convex to the axis of abscissae, X.

Referring to fig. 8, N_1 is taken as the origin; and since a_1, a_2, and a_3, are the lengths of the ordinates, corresponding to the distances 0, m, and $2m$ from N_1, we have

$$a_1 = A \qquad (1),$$
$$a_2 = A + Bm + Cm^2 \qquad (2),$$
$$a_3 = A + 2Bm + 4Cm^2 \qquad (3).$$

From these equations we find that

$$A = a_1,$$
$$B = \frac{4a_2 - a_3 - 3a_1}{2m},$$
$$C = \frac{a_3 - 2a_2 + a_1}{2m^2},$$

and the equation to the parabolic curve, passing through P_1, P_2, and P_3, where P_1N_1 and N_1N_3 are the axes of Y and X respectively, is

$$Y = a_1 + \frac{4a_2 - a_3 - 3a_1}{2m}X + \frac{a_3 - 2a_2 + a_1}{2m^2}X^2.$$

* In this, as in our previous article, No. II., we necessarily assume that the reader is acquainted with what is called "Analytical Geometry" by some, and "Co-ordinate Geometry" by O'Brien and others. It is a beautiful subject of study, and the young reader who is unacquainted with it should master it without delay. Let him read "A Treatise on Plane Co-ordinate Geometry," Part I., by the Rev. M. O'Brien (Deighton's, Cambridge). Chapter X. of "Hall's Differential and Integral Calculus," on "Equations to Curves," will likewise furnish him with what he requires to know in order that he may understand what we mean when we speak of "the equation to the parabola," &c.

Whence the ordinate at any point in N_1N_3 may be obtained.

Let N_1N_3 be divided into a very large number $(2n)$ of equal parts, each part being equal to $\frac{m}{n}$; and at the points of division imagine ordinates y_0, y_1, y_2, y_3 &c., ... y_{2n} drawn perpendicular to N_1N_3; and their extremities joined by straight lines, thus forming $2n$ small trapeziums. Now it is evident that when n is very large, the very short lines joining the extremities of the ordinates coincide with the curve; and the sum of the small trapeziums thus formed, will be the parabolic curvilinear area required. From the general equation to the parabola

$$y_0 = A;$$
$$y_1 = A + B\frac{m}{n} + C\frac{m^2}{n^2};$$
$$y_3 = A + B\frac{2m}{n} + C\frac{2^2m^2}{n^2};$$
$$y_4 = A + B.\frac{3m}{n} + C.\frac{3^2m^2}{n^2};$$
$$\&c. = \quad \&c.$$
$$y_{2n} = A + B.\frac{\overline{2n-1}\cdot m}{n} + C\frac{\overline{2n-1}^2 \cdot m^2}{n^2}.$$

Area of first trapezium $= \frac{y_0 + y_1}{2} \times \frac{m}{n} = A\frac{m}{n} + \frac{B}{2}\frac{m^2}{n^2} + \frac{C}{2}.\frac{m^3}{n^3};$

„ second „ $= \frac{y_1 + y_3}{2} \times \frac{m}{n} = A\frac{m}{n} + \frac{B}{2}.\frac{3m^2}{n^2} + \frac{C}{2}(1^2 + 2^2)\frac{m^3}{n^3},$

„ third „ $= \frac{y_3 + y_5}{2} \times \frac{m}{n} = A.\frac{m}{n} + \frac{B}{2}.\frac{5m^2}{n^2} + \frac{C}{2}(2^2 + 3^2)\frac{m^3}{n^3};$

$\&c. = \quad \&c.$

„ last, or $2n$th $= \frac{y_{2n-1} + y_{2n}}{2} \times \frac{m}{n} = A\frac{m}{n} + \frac{B}{2}4n\overline{-1}.\frac{m^2}{n^2} + \frac{C}{2}\left\{\overline{2n-1}^2 + 2^2n^2\right\}\frac{m^3}{n^3}$

adding on both sides of the equations we have:—Sum of all the trapeziums =

$$A\left\{\frac{m}{n} + \frac{m}{n} + \frac{m}{n} + \&c.\text{ to } 2n \text{ terms}\right\}$$
$$+\frac{B}{2}\frac{m^2}{n^2}\left\{1 + 3 + 5 + 7 + \&c.\text{ to } 2n \text{ terms}\right\}*$$
$$+ C.\frac{m^3}{n^3}\left\{1^2 + 2^2 + 3^2 + \&c. \ldots\ldots + 2^2n^2\right\}\dagger - \frac{2^2n^2}{2}$$
$$= A \times 2m + 2Bm^2 + \frac{Cm^3}{3}\left(8 + \frac{1}{n^2}\right).$$

This last equation is true whatever n may be, but when n becomes infinitely large, in which case the sum of all the trapeziums gives the exact area of the figure of which the parabolic curve $P_1P_2P_3$ is a boundary; then $\frac{1}{n^2} = \frac{1}{\infty} = 0$. And the approximation to the curvilinear area $= 2Am + 2Bm^2 + \frac{8Cm^3}{3}$. Putting for A, B, and C, their values in terms of a_1 a_2 and a_3, we have

$$\text{area} = 2a_1m + (4a_2 - a_3 - 3a_1)m + \tfrac{4}{3}(a_3 - 2a_2 + a_1)m$$
$$= \frac{m}{3}\left\{6a_1 + 12a_2 - 3a_3 - 9a_1 + 4a_3 - 8a_2 + 4a_1\right\}$$
$$= \frac{m}{3}\left\{a_1 + 4a_2 + a_3\right\}.$$

* The series $1+3+5+7+9+\&c.$ – to $2n$ terms is thus found,

$$1 = 1^2$$
$$1 + 3 = 2^2$$
$$1 + 3 + 5 = 3^2$$
$$1 + 3 + 5 + 7 = 4^2$$
$$\&c. \quad = \&c.$$
$$1 + 3 + 5 + \&c., \text{ to } 2n \text{ terms} = (2n)^2 = 4n^2$$

† The sum of the series $1^2 + 2^2 + 3^2 + \&c. \ldots\ldots + (2n)^2$ may be readily found by the method of Indeterminate Coefficients. *Vide* Wood's "Algebra."

Assume $1^2 + 2^2 + 3^2 + \&c. \ldots\ldots + (2n)^2 = A + B(2n) + C(2n)^2 + D(2n)^3 + \&c.$, where A, B, C, &c., are unknown coefficients independent of $2n$; then writing $2n + 1$ for $2n$ we have

$$1^2 + 2^2 + 3^2 + \&c., + (2n)^2 + (2n+1)^2 = A + B(2n+1) + C(2n+1)^2 + D(2n+1)^3 + \&c.$$

Substracting the first equation from the second

$$(2n+1)^2 = B + C(4n+1) + D(12n^2 + 6n + 1) + 0;$$

all the co-efficients after D being separately equal to zero, since there are no terms on the left-hand side of the equation involving n^3, or the higher powers of n.

Equating like powers of n

$$12D = 4 \qquad \text{or } D = \tfrac{1}{3};$$
$$4C + 6D = 4 \qquad \text{or } C = \tfrac{1}{2};$$
$$B + C + D = 1 \qquad \text{or } B = \tfrac{1}{6};$$
$$\text{also } A = 0.$$

Therefore sum required $= \frac{2n}{6} + \frac{(2n)^2}{2} + \frac{(2n)^3}{3}$

and sum $- \frac{(2n)^2}{2} = \frac{n}{3}(1 + 8n^2) = \frac{n^3}{3}\left\{8 + \frac{1}{n^2}\right\}$

Digitized by Google

In the same manner the area between the ordinates P_3N_3 and P_5N_5, writing a_3, a_4, and a_5, for a_1, a_2, and a_3 respectively is $= \frac{m}{3}\left\{a_3+4a_4+a_5\right\}$

area between P_5N_5 and P_7N_7 is

$$\frac{m}{3}\left\{a_5+4a_6+a_7\right\}$$

and so on; until we come to the last set of three ordinates, the area corresponding to which is

$$\frac{m}{3}\left\{a_{2p-1}+4a_{2p}+a_{2p+1}\right\}$$

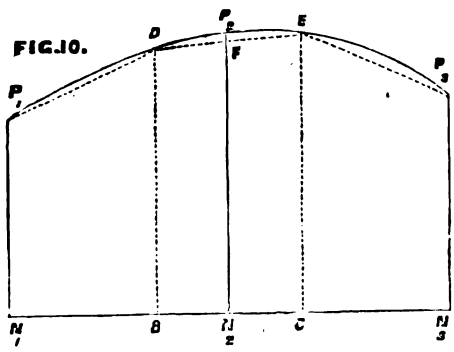
And therefore the whole curvilinear area of which P_1N_1 and $P_{2p+1}N_{2p+1}$ are the first and last ordinates respectively is

$$= \frac{m}{3}\left\{a_1+a_{2p+1}+4\,(a_2+a_4+a_6+\&c....+a_{2p})\ +2\,(a_3+a_5+a_7+\&c....+a_{2p-1})\right\}$$

From this expression we get the following rule to find any curvilinear area, such as is represented in Fig. 8:—

RULE. *Divide the line N_1N_{2p+1} into an even number of equal portions, and through the points of division let the corresponding odd number of ordinates be drawn perpendicular to N_1N_{2p+1} meeting the curve: and, to the sum of the first and last ordinates, add four times the sum of the even ordinates, and twice the sum of all the odd ordinates except the first and last, and multiply this sum by one-third the common distance between the ordinates.*

FIG. 10.



This is commonly called the Rule 2. A proof of this rule is given by M. Poncelet in his "Mécanique Industrielle," and as it is very simple and ingenious we shall give it here, observing that it previously appeared in the MECHANICS' MAGAZINE, No. 1413.

Take $P_1P_3N_3N_1$ (a portion of Fig. 8,) as in Fig. 10, and let a_1 a_2 and a_3 represent the ordinates P_1N_1, P_2N_2, P_3N_3, and m the common distance between them. Divide N_1N_3 into *three* equal portions, and through the points of division B and C, let BD and CE be drawn perpendicular to N_1N_3, meeting the curve in the points D and E. Join P_1D, DE, and EP_3, by straight lines, and let DE cut P_2N_2 in the point F. The common distance between these new ordinates will be $\frac{2}{3}N_1N_2 = \frac{2}{3}m$. Then if $\frac{2}{3}m$ be not very large, an approximation to the curvilinear area will be the sum of the three trapeziums just formed.

Area of trapezium $P_1B = \frac{1}{2}(P_1N_1+BD)\times\frac{2}{3}m$;
" " " $DC = \frac{1}{2}(BD+CE)\times\frac{2}{3}m$;
" " " $EN_3 = \frac{1}{2}(CE+P_3N_3)\times\frac{2}{3}m$;

Therefore approximately the area $P_1N_3 = \frac{m}{3}\left\{P_1N_1+P_3N_3+2\,BD+2\,CE\right\}$.

Now $BD+CE=2N_2F$, and F is very near P_2, since the ordinates are not far apart; therefore $BD+CE=2P_2N_2$ very nearly; and $2\,BD+2\,CE=4a_2$.

Hence approximately the curvilinear area $P_1P_3N_3N_1 = \frac{m}{3}\left\{a_1+a_3+4a_2\right\}$.

Proceeding with the other portions, P_3N_5, P_5N_7, &c., of the figure as has been done above, the rule just stated will be obtained.

The artifice by which the area is thus simply obtained consists in assuming that $BD+CE$ is equal to $2a_2$. The effect of this assumption on the result will be to increase slightly the approximating area above that of the three trapeziums; and since the small segments outside the trapeziums have been neglected, this small increase will tend to make up the deficiency. This, as we have shown above, really amounts to supposing the area to be bounded by a common parabolic curve.

INDIAN ITEMS.

THE works on the Umritsur and Mooltan Railway have been stopped. The reason assigned is that no instructions have been received from home regarding the line, nor any information as to the engagement entered into between the Company and the Home Government. Preliminary works, such as staking-out, the collection of materials, &c., are still proceeding.——The electric telegraph has been completed to Cochin on the Malabar coast, and is now opened to the public.——With regard to the Madras pier, Lord Stanley observes in a despatch, dated Oct. 27, 1858:—"The committee admit the contractors' estimate of the cost of the several additions suggested in the erection of the pier to be reasonable, and they consider that it will be cheaply purchased for £103,616. The offer of the contractors for its construction for that sum has been formally accepted, with the understanding that their original specification is to be modified so as to include the several alterations proposed by the committee; and further, that the whole work shall be completed within 2½ years from the date of commencing operations at Madras."——The Berar and Eastern Coast of Indian Company (Limited), with a capital of £3,000,000, is announced. The line is proposed to run from Coringa, at the mouth of the Godavery, to Nagpore, with a branch to Hyderabad. From Coringa to Nagpore is 400 miles, and the cost of construction is estimated at £8,000 per mile. The promoters urge that the construction of their line would open up an extensive district which would afford this country a large supply of cotton.——The last advices announce the arrival out of 12 vessels, despatched from Liverpool last August by the Oriental Inland Steam Company. ——The electric telegraph has been laid down cheaply in Ceylon. From Colombo to Galle, 72 miles, cost £3,000, and another 72 miles, from Colombo to Kandy, about the same price. ——An English mercantile firm has been established in the Punjaub, at Umritsur and Hurecke, to deal with native merchants for borax, salt, saltpetre, &c., and iron. The latter, which is said to be of excellent quality, is charcoal iron.

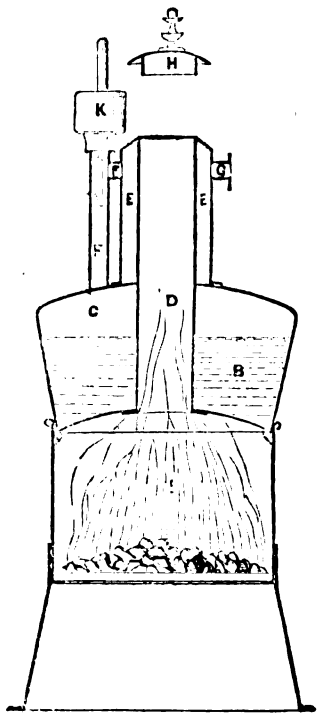
LIGHT-DRAUGHT STEAMERS FOR INDIA.

ON Monday last the light-draught steamer to which we made allusion in a recent Number, and which has been designed and built by Mr. Scott Russell for the Scinde Railway Company, was taken down the river on a trial trip. She is a singular vessel, being 200 feet long, 38 broad, and drawing only 2 feet of water with cargo and passengers on board. She is built of thin iron, and among other strengthening parts, has two longitudinal girders, running nearly throughout her length, and rising 10 feet above the deck, so as to form the bulkheads of a large deck-house containing apartments for passengers, after the fashion of American river steamers She is fitted with Mr. Russell's patent three-cylinder engines, and is driven by ordinary paddle-wheels. The engines worked very smoothly, and ran the vessel along at more than 13 knots per hour, with a draught of 22 inches. The trial was justly pronounced highly satisfactory, and Mr. Russell will proceed forthwith to build several additional vessels of a similar character, for the Indus. The spirited conduct of the Scinde Railway Company in starting vessels of this class upon the rivers of India will doubtless prove the beginning of a new era in the commercial interests of that country. The design of Mr. Scott Russell's vessel was selected from several competing designs, and it would be difficult to devise a better. Unfortunately the length proposed by him has been somewhat curtailed, otherwise a still better result would have been obtained on Monday. The engineer of the Company, Mr. Yarrow, was complimented at the trial by Mr. Russell, for the aid afforded by him in bringing about the accomplished success.

SUPERHEATING STEAM.

MR. TAPLIN, an experienced officer of the Engineering Department of H. M. Dockyard, Woolwich, sends us the following interesting and significant memorandum:—

Gentlemen,—I send the accompanying drawing of a model boiler, designed and brought before public notice by me in 1827, for producing superheated steam, presuming the subject may be of interest to some of the readers of your Magazine.



It will show that neither the practice of producing superheated steam, nor its use as a motive power, is at all a new feature in its application to the steam engine. Though perhaps it may with truth be asserted that it was not generally recognised to be economical and highly advantageous to actuate the steam engine by superheated steam, until Mr. Weathered's recent experiments in America and elsewhere were developed, with his project for using it in a mixed condition.

But as the steam boiler is that apparatus to which the various modes for superheating has to be applied, and boilers being of various forms and descriptions, it may be found expedient to adopt modified devices as may best suit each speciality.

With a view of making known to your readers the plan adopted by myself in 1827 for using superheated steam, unmixed, and more recently with large success on board the *Bremen* steam vessel, I have thought it might be even in the present advanced state of scientific improvements applicable on a still more extended scale, with much benefit to our mercantile marine. The original model and explanatory drawings may be seen in the Museum at Kensington, where they have been deposited. R. TAPLIN.

ARMSTRONG'S GUNS.—It was yesterday stated in Woolwich Arsenal that Mr Armstrong, the inventor of the wrought-iron rifle cannon, has entered into a contract with Her Majesty's Government, and that a considerable number of the guns are to be forthwith supplied for the use of the Artillery.

DODD AND PHILLIPS'S IMPROVED SLIDE VALVE.

FIG. 1.

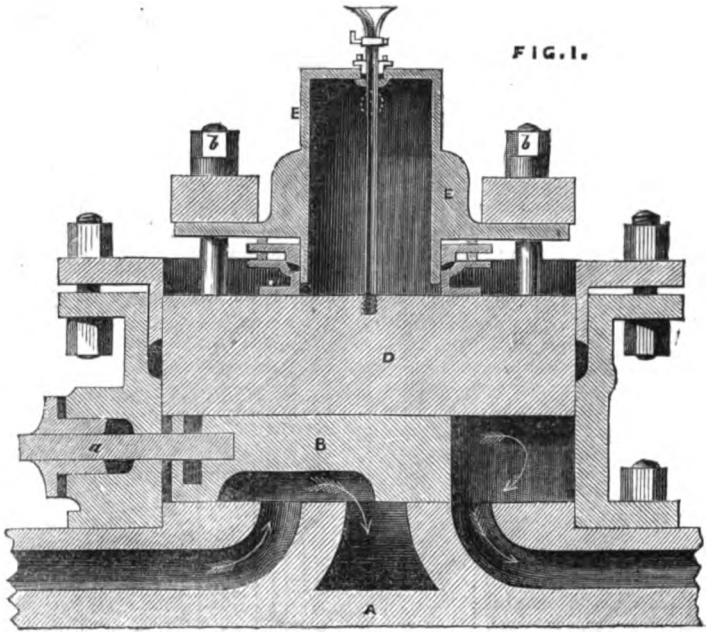

FIG. 2.

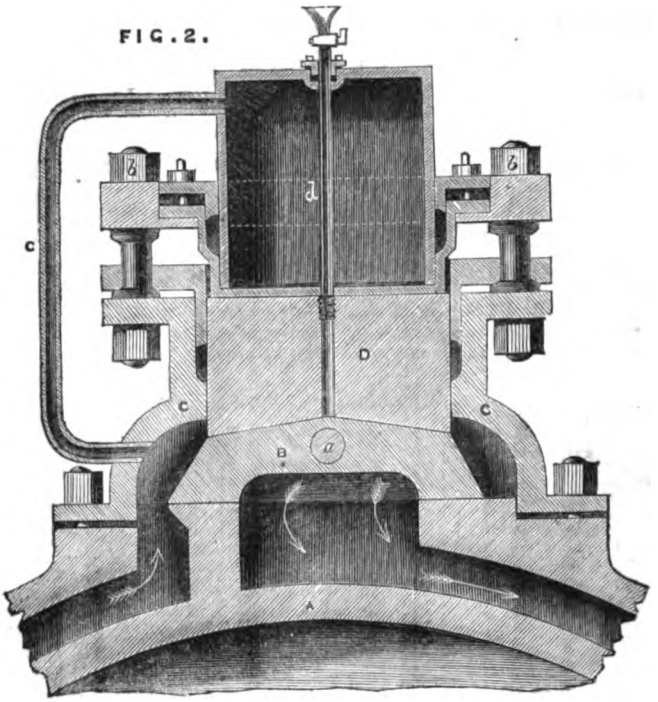


DODD AND PHILLIPS'S IMRROVED SLIDE VALVE.

MESSRS. J. DODD AND T. PHILLIPS, of Ruabon, Denbigh, have introduced the method of fitting balanced slide-valves for steam engines represented in the accompanying engravings. Fig. 1 is a longitudinal section, and Fig. 2. a transverse section. *A* is the cylinder, *B* the valve, *C* the valve case, and *D* the valve rod. Upon the top (or in some cases the side) of the valve is placed a block *D*, which is surmounted by a steam chamber *E*, which is fitted with an elastic joint, packed and kept down by bolts, *bb*, as shown in the figures. The steam chamber *E* communicates with the steam space by means of a pipe, *C*. The surfaces of contact of the block *D* and the back of the valve *B* are kept well lubricated by means of oil or other lubricant passed down through the small tube *d*, which extends entirely through the steam chamber, and enters a tube in the block *D* leading to the said surfaces. The dimensions of the chamber, &c., are so regulated as to admit of the desired amount of counterbalancing pressure being exerted upon the valve. The address of the inventors is 1 Lynn Cottages, Forest Row, Dalston.

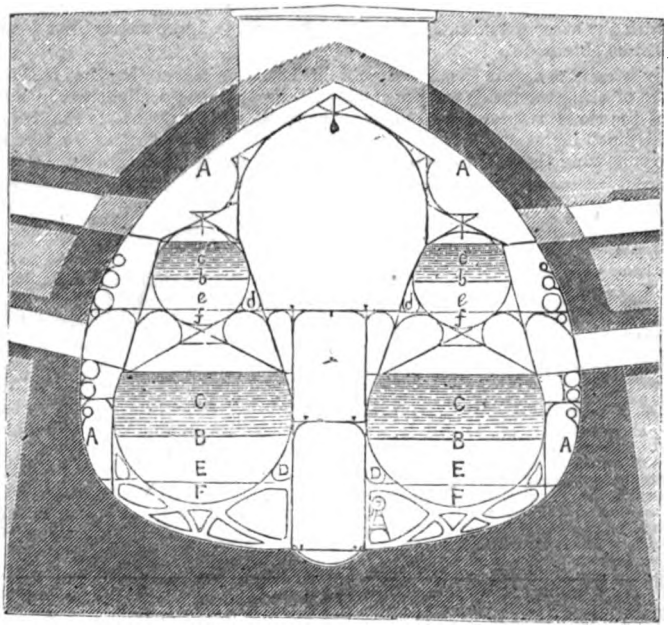
M. HOREAU'S SCHEME OF SEWERAGE.

AT the Hanover-square Rooms M. Hector Horeau, the well-known French architect, has been exhibiting and explaining his plans for the improvement of London. These are sufficiently comprehensive; but the principal points dwelt upon are the sanitary purification of the Thames, and the construction of quays and an esplanade upon its banks. The project of M. Horeau is to construct embankments on both sides of the Thames, having archways leading to the wharves—in front of which also would run canals for loading and unloading barges, wherever the width of the river would allow of the same. Within this embankment would be contained the sewage tunnel, including, besides high-level and low-level rivulets, no less than three railways for transporting manure and machinery, pipes for water and for gas, &c.

M. Horeau dwelt at some length upon the commercial advantage of the proposed wharves, which he affirms would be practicable in a financial point of view by reason of their valuable rental. A new street, to meet all the exigences of the present; or an increased circulation, and a general railway station in the centre of the metropolis, are also among the propositions of M. Horeau.

The following is M. Horeau's account of his "New Purifying Sewers for the Thames:"—

To avoid the difficulties of levels—to avoid expensive engineering—to avoid the formation of an offensive deposit, that no locality would admit of—to avoid the re-flowing of sewage towards the Metropolis—lastly, to economise public expenditure, and develop the riches of nature by natural processes,—such are the objects which the author proposes to obtain.



With this view, the proposed sewers are to consist of a vault, *A A A A*, of sufficient capacity to contain four iron gutters, or rivulets (two large and two small), *B B*, *b b*, supported by iron bearings independent of the construction of the vault; these rivulets are constructed at different heights, in order to facilitate their junction with the present sewers (which are at different levels), and would have a very slight fall, to be divided into as many basins as would be required by fixed sluices, open only at their summits, for the purpose of obtaining deposits, which would not arrest the ordinary current; moveable pipes or gutters being adopted for carrying into the adjoining rivulets the first matters which are not to be received in deposit, either to remove the manure or to allow of repairs. The purified water, *C C*, *c c*, which could be obtained in a short time at the summit of the deposits, might without injury be poured into the Thames, especially should this water be made to pass into channels containing purifying agents—such channels situate at *D D*, *d d*, under the rivulets or deposits. Underneath the purified water would naturally be found the liquid manure, *E E*, *e e*, which may be covered with oil to prevent the escape of its valuable gases. This liquid manure, which would increase in value towards the bottom, could be sent by pumps, pipes, or by casks, to the market gardens surrounding the Metropolis. After the liquid manure is drawn off, the deposit of solid manure, *F F*, *f f*, would be found at the bottom; this should be covered with lime or alum to preserve its quality and facilitate its being put into casks; the casks, to be raised by means of pulleys, could be placed on one of the three railways (with moveable floor), placed above each other between the rivulets. These railways would also serve for removing the manure, and for the transport of engines and other materials; observing that the upper railway could be more especially appropriated to the repairing and replacing those portions of the channels composing the different rivulets. This upper railway may also, in certain cases, communicate directly with the great lines of railway

Digitized by Google

at present existing. An extra gutter under the lower railway could receive the waste from the rivulets, pipes, gutters, or junctions, as also the cleaning water and any filtrations which may occur through the vault. Six galleries (three on each side of the vault) would be appropriated to the inspection of the junctions of the old sewers, to the proper disposal of the raw matters to decant into the various rivulets, for the fixing and repairing of the various pipes of water, of gas, and also for their numerous branches of distribution; observing here that electric wires, speaking tubes, and beer conductors (for the different workmen in the sewers) could thus find room on the sides of the vault. Moveable scaffoldings, ladders, syphons, pumps, cranes, and all useful machines, would facilitate the different services in the interior of the sewers, without encumbering the public way, as too often happens under the present system. The sewers in a state of uniform temperature, neither exposed to rain, wind, frost, or heat, would be lighted by jets of gas, establishing a salutary ventilation by means of draft chimneys placed at convenient distances; the workmen should be not only permitted but even induced to smoke. Artificial lighting may be assisted by daylight, by reflectors, or by apertures required for works and for the several workshops established near the course of the proposed sewers. "In the proposed new Purifying Sewers, which, as may be required, can be executed on a greater or smaller scale, which could be doubled, tripled, diminished, and even completely stopped, at the meetings of rivers or canals, or at the entrances of docks, and which could be crossed by existing pipes of water and gas, the intelligent reader will perceive," says M. Horeau, "a series of advantages which collectively would greatly benefit those concerned in purifying the Thames, by the sale of rich manures, by arrangements with water and gas companies, who may avail themselves of the sewers, by obtaining, gratis, on the shore of the Thames, and elsewhere along the course of the sewers, a ground-plot (within the sewer) for manufacturing manure, and, moreover, localities which could be conveniently appropriated for public buildings, as, for example, *Government Offices*. To this project for purifying sewers, enriching agriculture, and rendering salubrious the river and the Metropolis, I will add that a new branch of the Thames from Greenwich-marsh to Barnes would turn the waters to better account for navigation and commerce, and prevent the pollution of the river. But here I stop. These grave questions do not come within the scope of a summary description of sewers. If I have ventured these few ideas, it is that in matters of edility all considerations are bound up together; for London, and especially the City, is of all places in the world the least improving, notwithstanding that its buildings are combustible and of little value; and that the population frequently impedes the circulation required for commercial activity. Is it not time for the capital of the country where the first railways were formed—where the penny postage was established (copied or envied by so many countries)—where the first universal exhibition was formed—where are united telegraphically all the nations of the globe, and where a rare political security is enjoyed—is it not time this capital should arise nobly from its unaccountable lethargy of edility, and combine its different requirements for the purpose of facilitating their execution; and in order that it should become that which it ought to be—the worthy METROPOLIS OF THE COMMERCE OF THE WORLD!"

THE CONSERVATION OF FORCE.

(*Concluded from page* 75.)

THE same method is observable in the author's notice of the steam engine in its connection with the conservation-of-force theory. The above extract is intended to elucidate his view of this particular branch of the subject. In the following the same view, though impertectly, is more fully set forth:—

". . . . In the action of an ordinary steam engine, the heat from the furnace, having expanded the water of the boiler and raised the piston, a mechanical motion is produced; but this cannot be continued without a renewal of the heat or the contraction of the expanded water. This is done by the condenser and the piston descends; but then we have, in fact, transferred the heat from the furnace to the condenser, and in the transfer effected mechanical motion. Whether mechanical motion produced by heat be viewed as the effect of the transfer of heat, or as a conversion of heat into motion, is, perhaps, more a question of terms than of reality. . . . .

". . . . To produce continuous motion, or the up and down strokes of a piston, we must heat and cool, just as with a magnetic machine we must magnetise and demagnetise, in order to produce a continuous or useful mechanical power; and although, from the impossibility of insulating heat, some heat is apparently lost in the process, the result may be said to be effected by the transfer of heat from the hot to the cold body, from the furnace to the condenser. But we may equally well say that the heat has been converted into mechanical force, and the mechanical force back into heat; the effects are always correlative, as are the mechanical effects of an air pump, with which, as we dilate the air on one side, we condense it on the other; and as we cannot dilate without the reciprocal condensation, so we heat without reciprocal cooling, or *vice versâ*.

"Though the expansion of the air, steam, &c., is in itself a mechanical effect; yet to raise a piston we must have an excess of power beyond that which would produce the measure of expansion actually produced, and equal to the mechanical power required. Thus to raise a piston whose resistance is equal to two pounds, would require twice the elastic force of air which would be required to raise to the same height a piston whose resistance equalled one pound.

"In treating of motion we have seen that a certain amount of heat is produced by a certain mechanical action, and that this has been measured for several cases in the experiments of Mr. Joule. I am not aware that the converse proposition, or the amount of mechanical work which is produced by a given quantity of heat, has been directly established by experiment, though some approximative results in particular cases have been given. Theoretically it should be the same—that is to say, if a fall of 772 lbs. through a space of one foot will raise the temperature of 1 lb. of water one degree of Fahrenheit, then the fall in the temperature of 1 lb. of water through one degree Fahrenheit should be equal to raise 772 lbs. through a space of one foot—a result which certainly, at first sight, looks startling. I have endeavoured to give a proof (by showing the anomaly to which the contrary conclusion would lead) that whatever amount of mechanical power is produced by one mode of application of heat should, in theory, be equally produced by any other mode. But in practice the difference is immense; and, therefore, it becomes a question of great interest practically to ascertain what is the most convenient medium on which to apply the heat employed, and the best machinery for economising it."

Mr. Grove enunciates strange dogmas. He tells us that the condenser is an indispensable part of the steam-engine, notwithstanding he cannot be ignorant of the fact, that all locomotive engines work extremely well without its aid. Alternate heating and cooling is by no means absolutely necessary in the application of heat as a motive power. The condenser is used simply on the ground of economy, because it enables the engineer to eliminate, to some extent, the external opposing atmospheric pressure from his machine. Were it not for this external pressure of the atmosphere, the condenser would be of no use whatever, and the condensing engine would be no more economical than the locomotive.

That Mr. Joule or any one else has, by satisfactory experiment, established as a truth that 772 units of work, and the heat requisite to raise 1lb. of water one degree of Fahrenheit are reciprocal equivalents, I do not believe. We are told that Mr. Joule, in the experiments which he made to discover the mechanical equivalent of heat, employed a weight attached to a string to turn a paddle-wheel in a bath of water or of other fluids. The heat generated in the fluid wheel, &c., was, I suppose, equated with the work done by the falling weight. And from this questionable kind of experiment, Mr. Joule concluded that mechanical equivalent of one degree of Fahrenheit added to or abstracted from the temperature of one pound of water is equivalent to 772 units of work. I am not inclined to admit such a deduction from such experiments, unless it be proved that the falling weight has produced no effect besides that of raising the temperature of the fluid, and unless it be proved that the increased temperature of fluid is not coupled with a corresponding diminution of temperature in surrounding bodies. The extreme delicacy of which Mr. Grove says belonged to Mr. Joule's experiments is of little avail for his results if there be, as I think, a radical defect in his logic.

Mr. Grove's theory has a wider application, and therefore is liable to include a still larger amount of error. According to him the amount of heat which will increase the temperature of a pound of water one degree of Fahrenheit, to whatever medium applied, ought always to yield the mechanical equivalent, 772 units of work. What astonishes me is, that he does not seem at all disgusted with his theory, even when he finds that "in practice there is an immense difference." This constancy to a theory in adversity would, I dare say, be very charming to a sentimental mind. The rule I should follow, however, would be to reject every theory requiring uniformity, if practice give "immense" variation. With different media Mr. Grove acknowledges his theory does not hold. Does it hold even for the same medium? In the case of steam, is the duty of the engine always the same even if the same engine, the same boiler are used, if the steam be generated at various pressures? If the same engine and boiler be used, will a bushel of coals produce the same useful effect if applied to generate steam at two atmospheres as if applied to generate it at three atmospheres? The fuel required to transform a cubic foot of water into steam is said to be nearly the same, whatever be the pressure under which the steam is generated. Now, a cubic foot of water turned into steam at a pressure of three atmospheres, will yield a much greater amount of work than the same weight of steam at two atmospheres. And the result in the condenser is also precisely the same, for it requires the same proportion by weight of water to condense the steam, and the whole is left at the same temperature. Hence the mechanical equivalent of heat as used in generating steam varies with the pressure of the steam. The whole doctrine of steam and of the steam engine requires immediate reform if Mr. Grove's interpretation of natural phenomena be well founded; and I recommend it to his notice, and to the notice of those scientific gentlemen who teach the conservation of force and interpret it as he does. According to the common theory of steam it requires the same amount of fuel to heat 29 cubic feet of water from 60° to 100° Fahrenheit, as to evaporate one cubic foot of water into steam under any pressure whatever. And according to the same doctrine 28 cubic feet of water at 60°, if put in communication with the steam obtained by the evaporation of one cubic foot of water, will condense it and form a result of 29 cubic feet of water at 100°, and this will be the result whatever change of expansion, and consequent variation of pressure and temperature, may have taken place in the passage from the boiler to the condenser, provided only that no interchange of heat has happened between the steam and other bodies before it reaches the condenser. If all this be correct it may be readily proved that the result in the condenser is a full equivalent for fuel consumed in the furnace, and that nature does the work of the steam engine into the bargain. If the lowering the temperature of a pound of water one degree of Fahrenheit give a mechanical equivalent of 772 units of work, then the mechanical equivalent of the fuel necessary to raise 29 cubic feet of water from 60° to 100° Fahrenheit is equal to

$$29 \times 40 \times 62{\cdot}5 = 72{,}500 \text{ units of work.}$$

The mechanical equivalent of the heat required to evaporate one cubic foot of water into steam must be exactly the same. Therefore, as none of the heat is lost in the passage through the engine, none of its mechanical power has been consumed. This is a decided proof that either the common theory or Mr. Grove's is in serious error. I am disposed to think that Mr. Grove is wrong. I am quite convinced that the heat which appears on occasions of friction, collision, &c., is not paid for by a disappearance of mechanical motion. For no motion is ever lost in these phenomena. Hence, I do not demand of nature that a development of mechanical action, in which no absolute gain of motion takes place, shall be compensated for by a disappearance of heat. Yours, &c.,

A MECHANIC.

SUFFIELD'S ENGINE-ROOM TELEGRAPH.—An improved marine engine-room telegraph, lately introduced by Messrs. Suffield and Co., engineers, &c., of Bermondsey Wall, and Fenchurch Street, London, has been tried and proved this week, on board H. M. ship *Cressy*, at Sheerness. The trials made with it were very severe, and the success of the instrument surpassed all expectation, giving great satisfaction, we believe, to Captain Halsted, who will report upon it to the Admiralty.

CAPTAIN NORTON'S RIFLE BULLET.—The *Times* of yesterday again notices this bullet, saying, "a favourable report has been made to the authorities of the result of the experiments with the new description of rifle bullets invented by Captain J. Norton." In a previous number of the same paper, a letter from Mr. Busk, the author of a well-known work on the rifle, was published. Mr. Busk speaks strongly in favour of the new bullet, highly eulogizes the inventive skill of the gallant "Peninsular Veteran," and adds that in his case, as in many others, "the labour of a life has been devoted to the service of an ungrateful country, without one word of encouragement, or even a bare token of approval." This applies only to the neglect of the Government departments, the press having continually and warmly urged Captain Norton's many claims. We really hope the Government will now do justice to this old and very able officer.

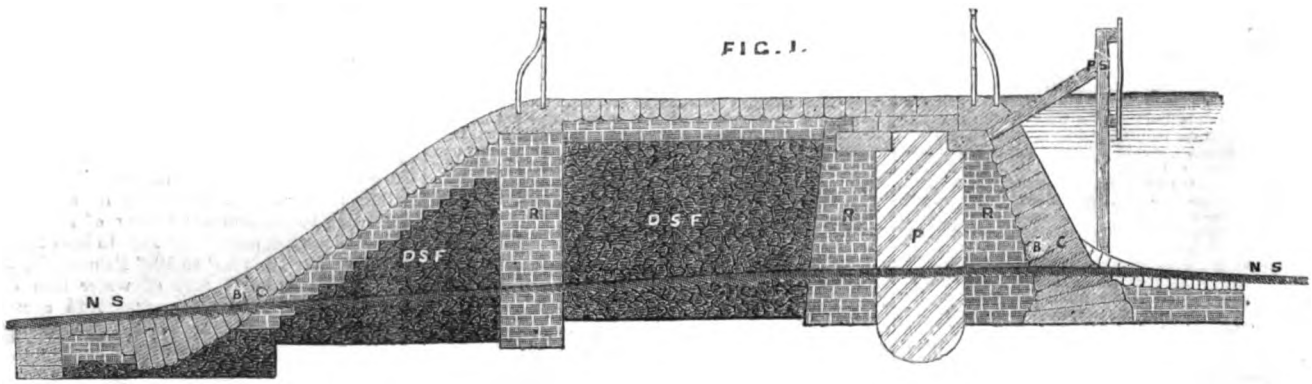
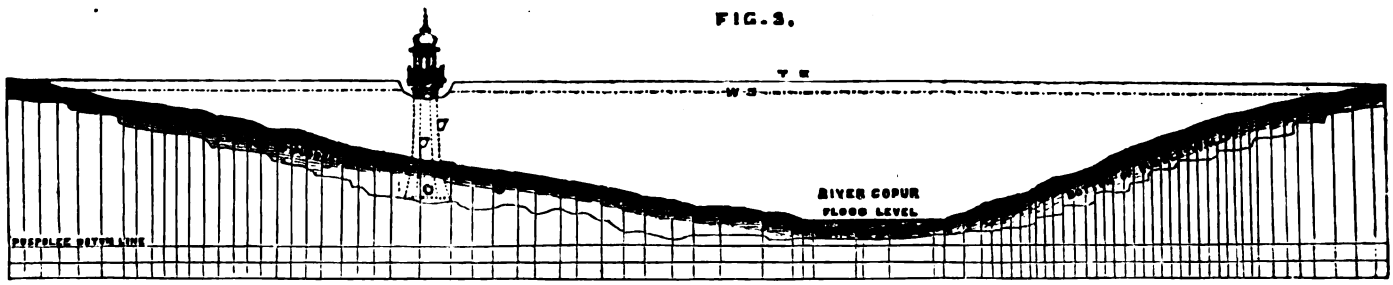
THE BOMBAY WATERWORKS.





THE BOMBAY WATER-WORKS.

THE water-works at Bombay having been deemed of so much importance that they alone of all the public works in India have been proceeded with during the mutiny, and Colonel Sykes having in the House of Commons, on the first business night of the session, alluded to their completion during the present year as a great source of satisfaction, we have made the necessary arrangements for presenting our readers this week with a description of them. In doing this we have been greatly aided by the paper which the able engineer of the works, Mr. Henry Conybeare, C.E., read a few months since at the Institution of Civil Engineers. We shall follow his remarks as nearly as our space will admit.

The geological conditions of Bombay being such as to leave the inhabitants destitute of springs, the population of the place was but a few years since mainly dependent for water during nine months out of the twelve on the rain caught during the monsoon in old quarries, and other shallow excavations, which, being situated in the midst of a peculiarly dense and dirty population, became thoroughly contaminated as the dry season advanced. The annual prevalence of cholera at Bombay at that season, was mainly due to the extreme pollution of the only water the lower classes could then obtain.

The first project for increasing the water supply of Bombay, by means of surface collection in the adjacent high ground (the only practicable plan in the case of Bombay), is due to Colonel Sykes, late Chairman of the Honourable the East India Company, to whom we have already referred. He proposed, nearly thirty years ago, to collect and impound the rain-water falling on the high ground at the south-western extremity of the Island of Bombay. This would now, however, be altogether inadequate. Colonel Sykes' plan was revived by Colonel Jervis in 1845, but without any material alteration. The second feasible scheme was that of the late Mr. Rivett, who proposed to bring the water collected and stored in the high grounds of the adjacent Island of Trombay. In 1846, Major Crawford, of the Bombay Engineers, pointed out the capabilities of the Valley of the River Goper, in the adjoining Island of Salsette. But the Goper scheme lay dormant, with the others, until the water famine of 1851. Lieutenant De Lisle was then instructed to make a preliminary survey of the valley; and soon after, the question was referred to Mr. Conybeare, whose report on "the amount of the existing water supply of Bombay, and the various means which had been proposed, or might be adopted, for increasing it," was published by the Bombay Government. The conclusion arrived at was, that the Valley of the Goper was the only possible source whence an adequate supply could be obtained. It was recommended that detailed contour surveys should be made, with the view of determining the capacity of whatever eligible sites for water storage it afforded; and that plans and estimates should be prepared, to ascertain the cost of rendering a supply from this source available to the population of Bombay. The course thus recommended was adopted by the Government, and Mr. Conybeare was selected as the Engineer, to prepare the surveys and estimates, and to design and execute the works. The rapid rate at which the population was increasing rendered it imperative that the works should be designed with a special view to their future extension, as the population increased.

On referring to a map it will be seen that the high ground, in which the Goper takes its rise, affords five admirable sites for storage reservoirs; two of which, the basins of Vehar and of Poway, are as large as lakes. The most northern of these reservoir sites is in the immediate neighbourhood of the celebrated cave temples of Kenerry, at the head of an adjoining valley; so that it will have to be connected with the Goper series of reservoirs by a short length of syphon main. Of these basins, that of Vehar is the most capacious. Investigation satisfied Mr. Conybeare that the Vehar basin was adequate to the collection and storage of all the water that could be required for some years, and the works for water storage were therefore confined, in the first instance, to the construction of this single artificial lake. It was, however, arranged that while these works were in progress contour surveys of the other reservoir sites should be carried out, so as to determine to what extent, and at what cost, the supply might be at any time increased, by the construction of any one or of all of them.

After numerous calculations and mature reflection, the design of the works was decided upon and prepared by Mr. Conybeare. When filled up to the level of the waste weir the maximum depth of the Vehar lake is 80 feet. It covers an area of 1,394 acres, and stands 180 feet above the general level of Bombay. The water is impounded by three dams. The principal dam contains a little under 300,000 cubic yards. The top width of the principal embankment (which has to carry a road) is 24 feet; that of the two others is 20 feet. The inner slope of all three embankments is 3 horizontal to 1 vertical, and the outer slope 2½ to 1. These embankments were specified to be formed in regular layers of not more than 6 inches in thickness, each properly watered, punned, and consolidated. The puddle-walls of all the embankments are 10 feet wide at the top, and have a regular batter on each side, at the rate of 1 in 8. The trenches for the foundations have been excavated through the surface rock, and past all surface springs, into the solid basalt below. The slopes of all the embankments, and also the top surface, are covered with stone pitching, at least 12 inches in depth, roughly squared by the hammer, and solidly set by hand; an additional thickness of 12 inches of broken stone being laid underneath. The pitching of the top surface and of the external slopes of the dams is necessary to protect the slopes from the effect of the heavy down-pour, to which the hill districts of India are subject during the rainy season; the duration of the intervening dry season being too great to allow of their protection by means of turfing or vegetation.

The waste weir, shown in section in Fig. 1 of the accompanying engravings, is 358 feet in length. It has a horizontal top width of 20 feet; and is faced throughout with chisel-dressed ashlar, set in cement. A breakwater is affixed to the inner margin of the waste weir, to prevent the water being blown over in high winds. *N S* is the natural surface; *D S F* is dry stone filling; *B C* is block in course in cement; *R* is rubble, and *P* puddle.

The water is drawn from the reservoir through a tower, Fig. 2, placed as shown in Fig. 3, which is a longitudinal section through the axis of the embankment. The line *T E* indicates the top of the embankment, and the line *W S* the water surface when filled. The tower is provided with four inlets, fixed at vertical intervals of 16 feet apart. These inlets are 41 inches in diameter, and are provided with conical plug seats, faced with gun metal. The three inlets not in use are kept closed by conical plugs, fitted by grinding. These plugs are suspended exactly over their seats from the balcony above, and are raised or lowered at will by crane-work at the top of the tower. The inlet in use is surmounted by a wrought-iron straining cage, covered with No. 30 gauze copper wire, and fixed to a conical ring, fitting into the inlet orifice, in the same manner as the plugs, and equally cable of being raised and lowered at pleasure. This strainer presents a surface of 54 square feet. The gauze is affixed to the cage so as to admit of its being changed from a boat, when clogged, in ten minutes after the cage has been drawn up to the surface —or a plug may be substituted for the cage, and lowered to its place in the same time. At the bottom of the inlet well, and exactly over the orifice of the supply main, another conical seat is fixed, into which a similar straining cage (but with No. 40 gauze copper wire, and presenting a surface of 90 square feet) is inserted. The water thus passes through two strainers before it starts for Bombay. The primary object of this arrangement was to obtain, in the town distribution, the benefit of the additional head of water—due to the depth of the lake, which would have been lost had the water been strained (as in the more usual arrangement) at the outside foot of the dam. It was also thought advisable to avoid the use of such heavy sluice-valves as would be required for closing inlets 41 inches in diameter, in positions in which it would be difficult to get at them, for the purpose of effecting any necessary repair. Without this arrangement, the utmost head obtainable would have been insufficient for a distribution by gravitation alone.

The gathering grounds are of basalt. The surface, where not covered deeply by the waters of the lake, rises with so steep an acclivity as to have been long since denuded of any soil that could be washed away. The vegetation is all evergreen, and no human habitation is permitted, throughout the entire area of the gathering grounds. Under these conditions, and also taking the great depth and capacity of the lake into account, the author decided that filtration would be altogether superfluous. For the same reason, a sludge-pipe to drain the lowest level of the reservoir was deemed unnecessary. No considerable deposit is anticipated over any portion of the bottom; the little that takes place will probably be confined to the head of the lake, some miles distant from the outlet; and were it otherwise, a single sludge-pipe could have no appreciable effect in keeping down or scouring off the deposit over an area of 1,400 acres.

Mr. Conybeare being of opinion that there is no engineering structure to which an appropriate and æsthetic expression may not be given, with economy and advantage, made the design of the inlet tower at Vehar an attempt in this direction (Fig. 4). It is an example of the application of a style of architecture very little known in England, but which has capabilities peculiarly adapting it to the architectural and structural requirements of a large class of modern constructions, especially for those into which cast-iron and glass enter largely, and the towers of suspension-bridges. But the application of this style is by no means limited to structures of cast-iron, for out of the infinitively varied, and as yet almost untouched magazine of ornamental detail afforded by Indian architecture, much might be culled that would suit any material and harmonise with any style. The upper part of the tower is further illustrated in the plan, Fig. 5, in which *T T* is a quarter plan of the top of the tower, *M N* a quarter plan on line *M N* of Fig. 2, *O P* quarter plan on line *O P*, Fig. 2, *K L* quarter plan on line *K L*, and *G* is the gangway leading from the tower to the embankment. The supply main traversing the dam is 41 inches interior diameter, and the metal is 1¼ inch thick. It is laid in a level trench, excavated in the rock, and filled with concrete.

THE BOMBAY WATERWORKS.

FIG. 2.

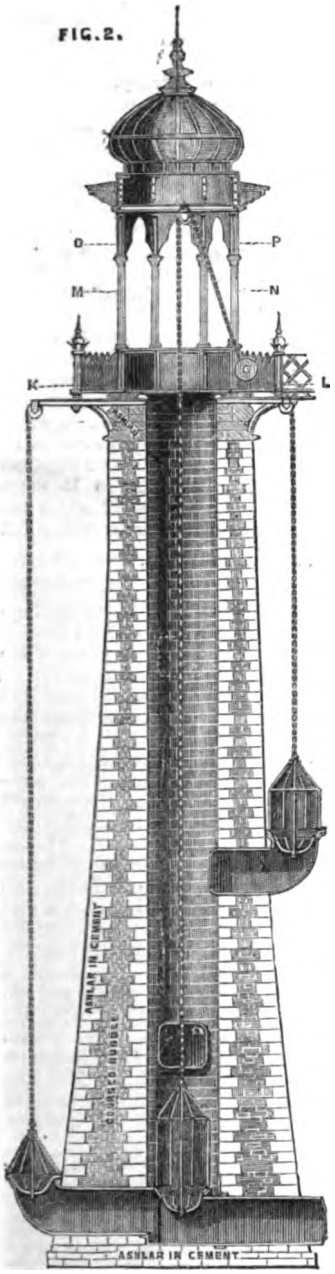

FIG. 4.

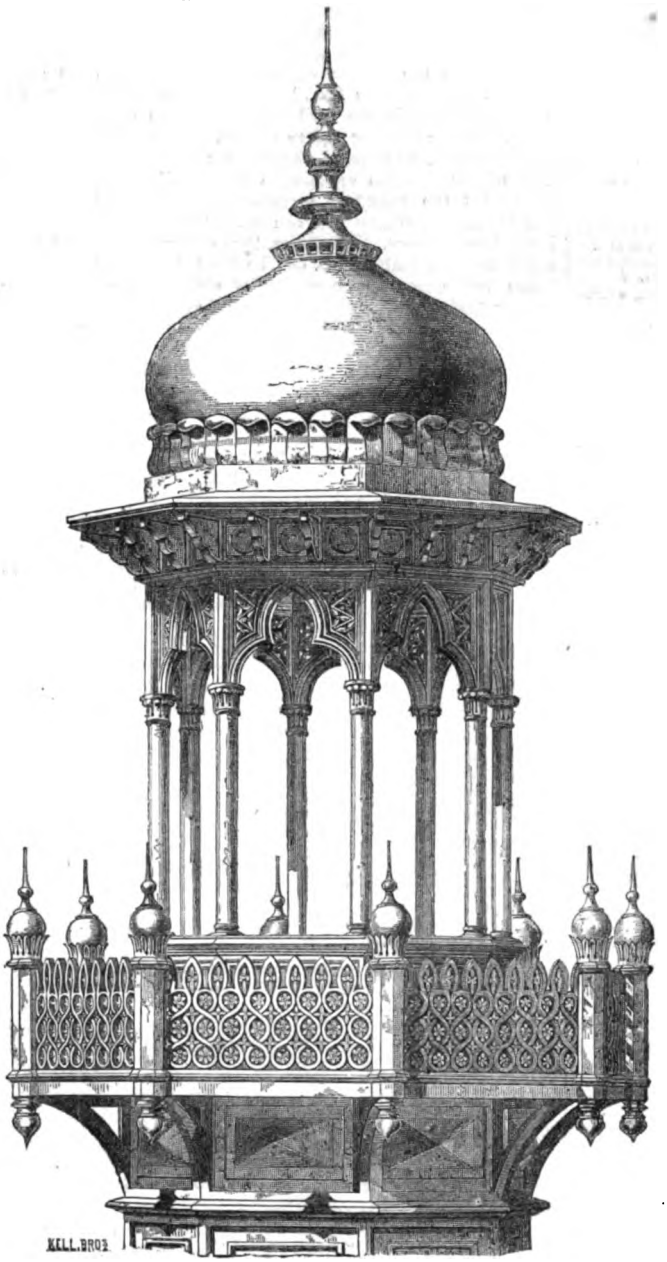

FIG. 5.

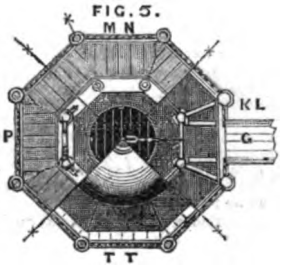

FIG. 7.

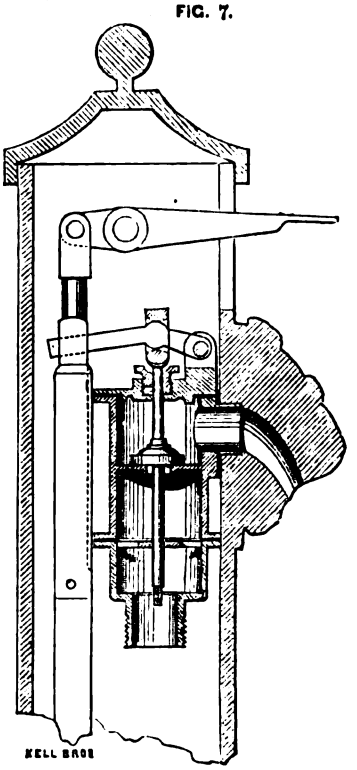

FIG. 6.

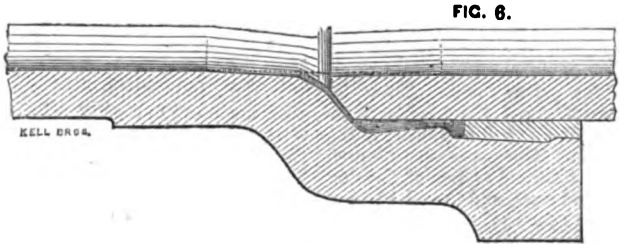

The portion traversing the puddle trench is supported on ashlar masonry, set in cement, puddled to a depth of 6 inches, and then arched over with four rings of brick in cement; two teak-wood washers being affixed transversely on the pipes, to prevent any water from passing between the pipes and the puddle.

At the sluice-house, situated at the outside foot of the dam, the large main, 41 inches in diameter, bifurcates into two mains, each 32 inches in diameter, both of which are eventually to be continued into Bombay; only one has been laid, in the first instance, as that suffices for the present requirements of the population. The length of the pipe, of 32 inches diameter, between the Vehar Lake and Bombay is 13 miles 6 furlongs and 160 yards, of which the last 7 miles are laid alongside the Great Indian Peninsula Railway. The mode of joining the pipes is shown in Fig. 6. The supply is distributed through the town and suburbs by means of branch and street mains in the usual manner. The only peculiarity in the distribution is the large proportion of the population supplied gratuitously, by means of self-closing public conduits (Fig. 7). The design of these appliances was, therefore, the subject of much consideration. The pattern finally adopted can be made to close either with or against the water pressure, by simply taking out and reversing the spindle valve; the counter-weights admit of being exactly adjusted to the resistence at the various levels of the town, so as to leave in each case, whether closing with or against the water pressure, just so much preponderence as may be found sufficient to close the valves.

The contracts for the reservoir works in Salsette, and for all the pipe-laying, were let to Messrs. Bray Champney, of Leeds. The pipe contracts were executed by Messrs. D. Y. Stewart and Company, of Glasgow. All the larger sizes of sluice valves, the hydrants, and a portion of the special castings, where manufactured by Messrs. Simpson, of the Belgrave Iron Works, Pimlico. The sluice valves, 32 inches in diameter, are admirable specimens of workmanship. The valve is made in two segments, the smaller one being about one-fourth the area of the larger. By this arrangement, the valves are rendered capable of being closed or opened under the severest pressure, with a very trifling exertion of force. The smaller valves are on Underhay's system, which possesses the advantage of allowing the valve seat, as well as the valve itself, to be removed for the purpose of repair, without disturbing the laying of any portion of the mains. The water is delivered at Bombay under a pressure varying from 165 feet to 169 feet.

The conditions under which the work had to be executed were peculiar. The want of water was so grievously felt at Bombay that the Government and the public were impatient for the immediate completion of the works. But all the pipes and machinery had to be manufactured at a distance of 15,000 miles from Bombay, and it was a difficult matter to provide shipping to a single port for so large an amount of dead weight, within so short an interval. Moreover, it was only during the eight months of the fair season, from the 1st of October to the 1st of June, that work could be carried on to any extent in the interior of Salsette. During October and November, while the ground was drying up after the rains, jungle fever of an extremely malignant type prevailed in that locality, to an extent to create a very serious impediment to the effective prosecution of any large works. In the high country of Salsette the rains are too heavy and continuous to allow of any

Digitized by Google

work being carried on while they prevail; and the torrent that often pours down the gorge of the Goper at that season would inevitably sweep away any works for impounding its waters, left in an incomplete state when the rains set in, unless some provisional outlets were provided for its escape in some other direction.

Careful arrangements were made to meet the necessities of the case, and these arrangements have in all essential points been successfully carried out. The dams were just completed to the height required to insure safety, before the setting in of the first monsoon; the rainfall of which first monsoon was thus impounded and stored to the 56-feet contour; and the works will be in a complete state to receive the rains commencing in June next, by which rainfall the lake will be filled to the waste weir, and its surface extended over an area of 1,394 acres.

The only contretemps that has occurred has been occasioned by the difficulty experienced, especially since the commencement of the Indian mutiny, in providing shipping for the pipes with sufficient rapidity, but the effect of this delay will be merely to retard the completion of the detailed distribution in the town to some weeks beyond the specified date, which, as such delay will operate during the rainy season, when water is only too abundant, will be attended by no practical inconvenience.

In the execution of the works great credit is due to Mr. H. Walker, who has ably filled the office of resident engineer, and who carried out Mr. Conybeare's plans to his entire satisfaction. Upon Mr. Conybeare himself, as a professional man, the entire undertaking, from first to last, reflects great honour, and places him among the foremost engineers of the time.

Literature.

Miscellaneous Papers on Mechanical Subjects. By JOSEPH WHITWORTH, F.R.S. London: Longman, Brown, Green, Longmans, and Roberts. Manchester: J. and J. Thomson. 1858.

THE volume which Mr. Whitworth here presents to us has a peculiar value. It records the thoughts and observations of one of the most refined mechanical minds of the age, and at the same time shows the practical influences which those thoughts and observations have exerted. The contents of the volume have for the most part been published before, in the proceedings of various societies, and elsewhere; but they will be heartily welcomed in a collected form; the more so as they are associated with an original paper on rifled fire-arms, which all mechanical, and many naval and military men will seek with interest. There is something exceedingly pleasant and impressive in Mr. Whitworth's professional career. That faculty of the mind by which man corrects, refines, and perfects his instruments, and which is more than ordinarily strong in Mr. Whitworth, he has employed with the happiest results. Exercising his early powers, if we mistake not, in conjunction with Mr. Babbage, in the construction of the famous calculating machines, he soon learnt to acquire nicety of touch and mechanical delicacy. On coming out into the broad sphere of engineering operations these qualities led him to observe the rudeness and imperfection of many of the mechanical processes of that period; and this resulted in the production of the first paper in the volume before us, on "plane metallic surfaces," read at the British Association in Glasgow, 1840. We hardly need say that the system of "scraping," then recommended by Mr. Whitworth in place of "grinding," has now come into general if not universal use, and with immense reduction in the wear and tear of steam engine slide valves, &c. The next of the papers before us was on "A Uniform System of Screw Threads," and was read at the Institution of Civil Engineers in the following year (1841). This paper was followed by the abandonment of the old system of forming screws of all forms and sizes, and the adoption of uniform sets of screws for engineering works—a highly economical change. The next paper is the address delivered by Mr. Whitworth to the Institution of Civil Engineers at Glasgow, in 1856; and this is followed by the paper on "Standard Decimal Measures of Length," addressed to the same Institution at Manchester in 1857. These are deeply interesting papers, detailing the means by which the minutest lengths, sensible only to the touch, are measured. The perfection of measurement seems to be here attained. The decimal system is advocated with irresistible cogency. The last paper in the book is Mr. Whitworth's report on the New York Industrial Exhibition, in 1853, which is still sought after. But before it, comes the paper on "Rifled Fire-arms." And here we must state, that from the first we have looked anxiously for the success of Mr. Whitworth's proposed system of construction, and have never heard of, or announced, its failure in any instance without regret. There seems to be a fitness and suitability in the system which the "grooving" does not possess. We fear, however, the success of the polygonal-bore arms has hitherto been but small. In the chapter before us, Mr. Whitworth early remarks, we observe, that "the angular corners of the hexagon are always rounded." We considered the rounding a recent improvement, and think Mr. Whitworth can hardly intend to imply the contrary. He states, that either cylindrical or hexagonal bullets can be fired from his guns; but urges the necessity of employing a powder that ignites quickly with the cylindrical bullet, in order to expand it effectually into the angles of the bore. Knowing the difficulty with which marksmen judge of distances, he gives his bullets a small diameter, so that they fly fast, and move in a low trajectory, whereby the aim is made more sure than usual. For some purposes, such as firing through iron plates, through water, &c., he employs a long flat-fronted projectile, which is found to be scarcely inferior in any respect to a pointed one, and has many advantages. For firing through elastic materials, he uses hollow projectiles, which take out a core, leaving a hole that does not close up. These also penetrate masonry very efficiently. He gives a very quick turn to the rifling of his small arms—one turn in 20 inches for a military barrel—and objects to a varying turn, as "obviously injurious," "for besides altering the shape of the bullet it causes increased resistance at the muzzle—the very place where relief is wanted." This paper on fire-arms is very meagre—a fact which the author explains by saying that it has been drawn up rather with the view of offering some reply to many inquiries than with the intention of giving a detailed account of what has been done, or of presenting a complete treatise on the subject. It ought, however, to have contained some explanation of the failure of the cannon. There is a note at the end of the paper which may, we think, have had much to do with the publication of the volume, and which, in justice to the author, we with pleasure transcribe. It runs as follows:—

"It is right to state that from the time I first undertook, at the solicitation [!] of the Government, to render what assistance I could in the improvement of rifled fire-arms, I have always devoted my time and attention to them, without any remuneration whatever, even for personal expenses. The sums required have been advanced by myself; periodical accounts are sent in to the Government, and the advances have been repaid at its convenience."

We earnestly recommend this book to young engineers. It will refine and exalt their professional ideas, and otherwise greatly help them.

Remarks upon the Practicability and Advantage of Railway Communication in European and Asiatic Turkey. By Sir MACDONALD STEPHENSON. With Maps. London: John Weale, 59 High Holborn. 1859.

THIS publication has probably been put forth more with the view of eliciting articles in the press than with the desire to circulate the book itself extensively; but, as it comes to us as a literary production, we prefer treating *it* rather than its subject. The author is well known as an able and zealous promoter of railways in the East. In compliance with a requisition of the directors of the Ottoman Railway from Smyrna to Aidin, he has visited Smyrna and Constantinople, and finds that the first section, extending 40 miles from Smyrna, will be probably opened by September next. The second and third sections will be completed earlier than was anticipated, and the prospect of merchandize and passengers is very encouraging. After quoting some interesting documents, and noticing the trade of Smyrna, he proceeds to state that at Constantinople he urged upon the ministers of the Porte several reforms in connection with railway undertakings in Turkey. The ministers expressed themselves willing, and even anxious, to do what they could, and approved of his suggestion, that all parties concerned in those railways should co-operate in order to remove existing evils. Sir Macdonald next repeats the arguments made use of by him many years since in favour of railways in India, applies them to Turkish railways, and quotes from Mr. Alison's report on the commercial interests of Turkey. He subsequently enters upon a discussion respecting the extension of railways in that country, and urges the construction of a great trunk line, as direct as may be found practicable, connecting the European network of railways with the Turkish port or ports nearest to the East. The whole of Europe, Turkey, and Asia would be thus brought into close connection, "conferring mutual benefit," as he contends, "in the interests both of civilization and peace." That political objections to such a railway system will be devised by some we do not doubt; but, for our part, we look with great confidence for the progress of international communication, and anticipate nothing but good from it. We therefore cordially recommend our readers to study the pamphlet before us, in which the proposed extension is advocated with much ability, and which is accompanied by two excellent illustrative maps. They will find in it much valuable information on a subject of which the best of our untravelled countrymen know but little.

ASSOCIATION OF FOREMEN ENGINEERS.

AT a meeting of the Associated Foremen Engineers held on Saturday last, Mr. Joseph Newton was unanimously elected president in place of the late lamented Mr. Sheaves. Mr. Newton, in returning thanks for the honour spontaneously conferred upon him, took occasion to remark upon the sudden and untimely manner in which his predecessor had been removed from among them, and to eulogise his disinterested character. The president elect also invited those among the members of the Association who had not hitherto contributed papers, to prepare some forthwith. "It was not creditable," he said, "that there should be any among a body so practically valuable to the community as foremen engineers, and united as they were for common benefit—it was not creditable that there should be any who were mere listeners. They need not be particular as to the niceties of composition: it was information sound and substantial that was wanted—the results of experience gained and experiments made." Mr. Newton promised an inaugural address on the "Influences of Mechanical Science and Mechanical Men upon the Age in which we Live," for the first Saturday in the ensuing month, and, thanking his audience, again resumed his seat.

The distressing condition in which Mrs. Sheaves with an infant family of four children—sons—is left, occupied, at a later period, the attention of the meeting, and it was resolved to make the painful fact known to the mechanical public of the kingdom, in the hope of thus aiding a small stream of private benevolence which has fortunately set in towards the widow and orphans. It was hoped that the scientific press would not be averse to saying that Henry Grissell, Esq., of the Regent's Canal Iron Works, City Road London, would be happy to receive subscriptions in aid of the helpless family, or to answer any enquiries respecting them. The MECHANICS' MAGAZINE and the *Engineer* were especially mentioned, and *we* have pleasure in responding to the call. There must be, throughout the United Kingdom, hundreds situated as poor Mr. Sheaves was—foremen of factories—unable to make future provision for their families; though in the enjoyment of enough for the hour. Sudden calamity dashes to the ground in an instant the hopes and the determination of the most prudent—and death seals them in gloom. If a presentation to a charitable institution could be obtained for one of the children, that would be of immense service.

The meeting of Associated Foremen Engineers stands adjourned to the first Saturday in March, at 8 P.M. The Bay Tree Assembly Room, St. Swithen's Lane, City, is the meeting place.

NOTICES.

Several articles and letters stand over until next week.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 6d. per line for any number of insertions less than 13; for 13 insertions, 5d. per line; and for 52 insertions, 4d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can be received after 9 o'clock on Friday morning for the ensuing number.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Quarterly Meeting, Jan. 25, 1859.—W. FAIRBAIRN, F.R.S., &c., *President, in the Chair.*

Augustus de Morgan, V.P.R.A.S., &c., Professor of Mathematics in University College, London, and Arthur Cayley, Esq., F.R.S., &c., were elected honorary members of the Society.

M. Auguste le Jolis was elected a corresponding member.

The following gentlemen were elected ordinary members of the Society:—Mr. Thomas Carrick, Mr. James G. Lynde, the Rev. W. N. Molesworth, M.A., Mr. Henry Wilde, Mr. Richard Eadson, Mr. Thomas Sowler, Mr. James Dorrington, Mr. Henry Alexander Hurst, Mr. John Slagg, jun., Mr. George Mosley, Mr. William J. Rideout, Mr. James Thompson, Mr. Thomas Brittain, Mr. John William Mc Clure, Mr. M. L. Tait, Mr. Edward Coward, and Mr. John Watson.

Mr. Joseph Baxendell, F.R.A.S., was elected a member of the council, in place of the late Rev. H. H. Jones.

The president congratulated the meeting on the prosperous condition of the library, paying a high tribute to the zeal and industry of the honorary librarian, Mr. F. Ekman. The efforts which had been made to obtain an exchange of published transactions with learned institutions, at home and abroad, had been attended with great success, so that at present the most important of the scientific periodicals were in the possession of the Society.

IMPROVEMENTS IN SHIPBUILDING.

Mr. W. H. CRISPIN, of Stratford, London, sends us the following statement respecting his patent "improvements in the construction of ships and other sailing and steam vessels." The hull of the ship or other vessel, is constructed of iron, which may be considerably thinner than that usually employed in iron ships; the same being covered externally and internally with wooden planking, bolted completely through the iron and wood, and so arranged as to break joint, and thus add to the strength of the vessel. The external and internal wood-work should be caulked, in order effectually to prevent leakage. In some cases, it may be desirable to place the external planking in the ordinary horizontal manner, and to arrange the internal planking diagonally; and where great strength is required (as in ships of war) the series of wood, iron and wood, may be duplicated or tripled. The hull thus constructed admits of being sheathed with copper or other sheathing metal, and thus obviating one of the great objections to iron ships; while in the case of ships of war, the arrangement of wood and iron, in accordance with this invention, will prevent the disastrous consequences occasioned by the fragments of iron, when ships, built entirely of that material, are struck by shot, at the same time much greater facility being afforded for repairing the shot-holes. The deck of the ship or vessel may be constructed upon the same principles as the hull, in which case it may be desirable to place the lower or under planking transversely or across the ship.

THE WEDGWOOD STATUE.

A NUMBER of gentlemen assembled at Stoke-upon-Trent on Monday, January 24th, 1859, John Ridgway, Esq., in the chair; when it was resolved:—1. That the lapse of more than sixty years since the death of Josiah Wedgwood, F.R.S., has applied the test of time to his works, and shown that they possess that lasting power of pleasing, not dependent on having been suited to the fashion of his day; which, combined with the permanent and general usefulness of his labours, seem to point him out as a fit subject for a public monument. 2. That a statue be erected to his honour, by public subscription, the character and locality to be left to the decision of the subscribers.

Subscriptions to the Wedgwood Statue Fund will be received by the treasurer, E. J. Ridgway, Esq., Bank House, Hanley; or by the following banking houses:—Liverpool, Manchester, and the Potteries—the Manchester and Liverpool District Banking Company; Stone—William Moore, Esq.; London—Smith, Payne, and Smiths, and Coutts and Co.

GEOLOGISTS' ASSOCIATION.

ON Tuesday evening an address was delivered by Mr. Hyde Clarke, V. P., on the organization of a Continuous Geological Society, in aid of the Government Survey, by local sections or committees of the members contributing yearly reports on the progress of geology in their districts, which would embrace:—additions to the surveys and maps; discoveries of new minerals and fossils, particularly of building substances, as stones, slates, marbles, clays, cements, sands; accounts of mines, quarries, cuttings, wells, tunnels, &c.; observations on wells, springs, and water strata; the result of special inquiries into the building stones of the neighbourhood, or researches for economical substances. A discussion followed, in which the Rev. T. Wiltshire, V. P., and P. L. Simmonds, Bollaert, Mackie, Byerley, and Beaumont took part.

THE DRUID CLOAK.

IMPORTANT DECISION UNDER THE REGISTRATION OF DESIGNS ACT.

THE proceedings at Marlborough-street, and the decision arrived at, will have the effect of restoring confidence to that portion of the inventive public, who have hitherto sought the protection of the Act for the Registration of Designs. The article—a cloak that has become exceedingly fashionable, and called "The Druid"—had been extensively pirated, and two of the Oxford-street mantle warehousemen, who had not taken heed of previous printed notices, were summoned under the Act before Mr. Bingham, on Friday last. Mr. Orridge, the Barrister, briefly explained the complaint of the proprietor of "The Druid" Cloak, and the original cloak and the piratical copies being compared, the magistrate at once declared that it was in his power to visit this offence with a fine of at least £5 for every cloak sold. However, upon the interposition of the proprietors of "The Druid" Cloak (the Messrs. Jay) through their counsel, a nominal fine only was recorded, and the expenses, amounting to £8, were divided between the two defendants. The court was crowded during the hearing of the case with the members of the trade, and the feeling amongst the auditory was evidently that the little inventive talent which occasionally shows itself amongst the English caterers of fashion, ought to have every protection thrown around it. The result was consequently one of gratification, with an unqualified expression of regret that the representative of the wholesale house or houses by whom this piratical system is mainly supported, did not stand at the bar of the police court instead of the implicated retailers.

CURRENT EVENTS

IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

[COMPILED BY OUR OWN CORRESPONDENT.]

Armstrong's Gun—New Lines of Railway Projected: Forest of Dean to South Staffordshire—Prosperity of the Stockton and Darlington Railway—Engineer to the Merthyr Tydfil Local Board—"Wynne v. the Shropshire Union Railway" again—Shipwrecks in January—The Pit Explosion at Burslem, Astounding Heedlessness of Danger—Colliery Proprietors Fined—Infringements of the Factory Act—Steam-Engine for the Turnpike Road; The Marquis of Stafford upon it—Commencement of the Stratford-upon-Avon Railway—"Who built Wearmouth Bridge?" Was it Tom Payne? No!

MR. ARMSTRONG'S gun is noticed by the London correspondent of the *Manchester Guardian*, who says:—The projectile, like Mr. Whitworth's, is a bolt, not a round shot; but Mr. Armstrong's bolt is coated with lead, by means of which it adapts itself perfectly to the grooved gun. Besides getting rid of all windage and waste of propelling power Mr. Armstrong has devised machinery for training the gun with unerring accuracy; and by slots on which the gun traverses in its recoil, the piece once laid retains its elevation, however often fired. Mr. Armstrong has, moreover, invented a most ingenious time-fuse, to be used with shells discharged from his gun, of which the burning time can be altered for each discharge, if necessary, without unscrewing and fresh boring the fuse, as is now necessary whenever the range is changed. (This fuse was described and illustrated at p. 394 of the last volume of the MECHANICS' MAGAZINE.) A prick in a dial-plate attached to Armstrong's fuse, and which each captain of a gun makes in accordance with the word passed along the ship, will fix the time of the fuse's burning to a second, so that not an instant need be lost in altering fuses.——A line of railway connecting the mineral district of the Forest of Dean with the great manufacturing districts of East Worcester and South Staffordshire is contemplated. It is a line to run out of the Monmouth and Pontypool Railway, to pass through the iron and coal district of the Dean Forest, down to the Hereford, Ross, and Gloucester line, at Mitcheldean-road station, and from thence proceed by Aston Tryham, near Newent, again on by Dymock and Ledbury, where it would converge into the Worcester and Hereford Railway, now in course of construction, and then *viâ* Worcester, along the Oxford, Worcester, and Wolverhampton and Severn Valley Railways into the eastern portion of Worcestershire and South Staffordshire. There appears but little doubt that a railway so commenced would afford great accommodation, and be a speedy means of transit for all kinds of traffic. The other project talked of is a line of railway from Witney to Evesham, to be worked by a joint committee of the company originating it, and the Oxford, Worcester, and Wolverhampton Company, the former paying to the latter 50 per cent. of the receipts.——The directors of the Stockton and Darlington Railway announce that the traffic receipts of the past half-year have so far improved, as to justify them in recommending the payment of a dividend of 9½ per cent. per annum. Last half-year's dividend was 8½.——Mr. Alfred Taylor has been elected engineer to the Merthyr Tydfil Board of Health, from among fifty-three candidates.——Mr. Serjeant Shee has determined to re-open the arbitration case "Wynne *v.* The Shropshire Union Railway," his former award of damages to that gentleman, who is the Government Mining Inspector for North Staffordshire, for personal injuries sustained on the defendants' line, having been appealed against as excessive. Mr. Wynne is to be examined by three medical gentlemen on either side.——A published return shows that the number of wrecks in the month of January was 177.——At the coroner's inquiry into the circumstances attending the death of the four men at the Bycus Colliery last week in North Staffordshire, noticed last week, the jury returned a verdict of "Accidental Death," but severely censured the butty of the pit, who did his work so loosely that not only were the safety lamps of the pit out of order, but they were also all unlocked—it being the practice of the men to open them in the pit to light their pipes!——Mr. Eli Walsh, the proprietor of the Hayfold Colliery, has been convicted by the magistrates of Over Darwen, of neglecting to provide sufficient ventilation for his pits, and fined £2. The complaint was laid by Mr. Dickinson.——Messrs. Wm. Thompson and Sons, manufacturers, Whalley, have been convicted at the Blackburn County Petty Sessions, and fined £52 17s. 6d., for breaches of the Factory Act, in employing women and young persons in their mills after 6 o'clock on the 26th ult.——The Marquis of Stafford may now be seen travelling on the turnpike road, on a steam-engine which he has had constructed for the purpose in Buckingham. In front there is an ample seat, capable of accommodating four persons, and is guided by a handle in front. It weighs about twenty-two cwt., and is of two-horse power; it will travel at the rate of fourteen miles an hour.——The line of railway by which the world-renowned Stratford-upon-Avon is to be opened to the world, was commenced on Tuesday last amidst every allowable manifestation of rejoicing on the part of the people and the authorities.——"Who built Wearmouth bridge?" has been raised by a proposition of Mr. Summers, one of the Wearmouth bridge committee, to place upon the structure the following inscription:—"*Nil desperandum auspice Deo:* this bridge was invented and built by Rowland Burdon, Esq., M.P., A.D. 1796; strengthened and improved by Robert Stephenson, Esq., M.P., A.D. 1859." Ald. Ranson opposed the proposition on the ground that he believed that Mr. Burdon was not the inventor of the bridge, but that the honour of it properly belonged to Tom Payne; the matter having been postponed for further consideration, a minute of the commissioners of the bridge, dated Aug. 26, 1796, was produced in which Rowland Burdon, Esq., is thanked "for his liberality to the public in constructing the bridge upon principles for which he as inventor has a

Digitized by Google

patent, without accepting any pecuniary consideration for the patent right." Also there is read a letter from Mr. Burdon, of Castle Eden, the inventor's son, dated the 26th ult., in which that gentleman says: "I am in possession of the patent taken out by my father for the invention of Wearmouth bridge, and of documents, *e. g.*, letters from Mr. Wilson, &c., proving incontestably his right to it." Mr. Thomas Wilson, of Bishopwearmouth, referred to in the above letter, was the engineer of the bridge, under Mr. Burdon. A deputation of the committee waited upon Mr. Burdon last week, who produced the patent and other documents, and satisfied them that his father was the inventor of the bridge; so that it is now probable that the inscription proposed by Mr. Summers will be placed on the bridge.

NOTES FROM THE SOUTH WEST.

[FROM OUR OWN CORRESPONDENT.]

Cornwall Railway—Steamer for the Truro River—The Omeo (s.s.)—Mr. Brunel in Egypt—Gloucester and Cheltenham Tramway—A French Company near Cardiff—Somerset Central Railway: Wells Extension—Falmouth v. Southampton—Great Western and South Western Railway—Drinking Fountains at Plymouth—Water Supply of Plymouth—Naval Matters—St. Ives Harbour: Dawlish.

THE locomotive has at last penetrated to Truro, *via* the Cornwall Railway, and in a few days it is stated that an engine will be able to run from Truro up to the viaduct at St. Germains. This viaduct at present "stops the way." It is expected also that an engine will shortly cross the Royal Albert Bridge from the South Devon line. Between Plymouth and Saltash the works are "assuming quite an appearance of finish."——A new iron screw steamer has been launched at Bristol for the navigation of the Truro river. The vessel will leave Bristol as soon as possible, and is to commence running immediately between Truro and Falmouth. She is rather a small affair—about 70 feet long and 50 tons burden, drawing 4½ feet. Her engines are 18-horse power.——*Omeo*, (s. s.) for Melbourne, is lying in Plymouth Great Western docks, for new boilers.——A western paper states that Mr. Brunel, C.E., now in Egypt, will probably visit Suez, as the Viceroy is desirous of having his opinion on a projected transfer of the port of Suez to the Bay of Ataka, 10 miles south of the present landing place.——A "Gloucester and Cheltenham Tramway Abandonment Bill" is now before Parliament.——A large piece of land belonging to the Marquis of Bute, near Cardiff, has been taken by a French company for the manufacture of patent fuel by steam power.——The Wells Extension of the Somerset Central Railway has been examined by the Government inspector, but the period for opening for traffic has not yet been finally decided on.——The statements made at the late meeting in favour of docks, &c., at Falmouth, have, so far as they tend to the depreciation of Southampton, naturally excited a good deal of attention in the latter town. The great speech at the Falmouth meeting was made by a gentleman named Tilly, who is reported to have said that a Falmouth gentleman was told by Mr. B. M. Willcox, of the Peninsular and Oriental Company,—"We know very well that we shall have to land the mails and passengers at Falmouth, but we perfectly make up our minds that we shall take up our cargo at Southampton." This statement Mr. Willcox, supported by the Falmouth gentleman, has denied. Complaint is also made of the assertions made by Mr. Tilly with regard to the accommodation afforded by the Southampton docks. "For example," says a local paper, "he says the entrance to our (Southampton) inner dock is only 40 feet wide, when in reality it is 56 feet. They propose to make the tidal dock at Falmouth 80 feet wide at the entrance, whereas ours is 150 feet in width. . . The width of the entrance to our tidal dock, as before stated, is 150 feet, and to the close or inner dock, 56 feet. The tidal dock is 18 feet deep at low water springs, and the close dock will have a depth of 25 feet. The dimensions of our dry docks are as follows:—

	Eastern.	Middle.	Western.
Length from gates to head ...	538 ...	282 ...	346 feet.
,, on blocks	425 ...	233 ...	343 ,,
Width of gates	80 ...	51 ...	66 ,,
Depth of water over blocks at ordinary springs	25 ...	14 ...	20 ,,
Ditto neaps	21 ...	10 ...	16 ,,

With this accommodation for shipping already in existence, and with a large new dock in process of construction, we have not much fear of Falmouth competition."——Lord Lovaine, one of the Lords of the Admiralty, Admiral Sir George Seymour, and several engineer officers attached to the Portsmouth Dockyard, witnessed, at Haslar Creek, on Saturday, the operation of lowering one of the screw gun-boats from under the shed by machinery. The boat was afloat in 27 minutes from the commencement of the operation, which was pronounced to be completely successful. At this rate a fleet of gun-boats could be floated and got ready for action in two or three days.——The rolling stock of the Great Western Railway is returned as follows (broad and narrow gauge):—passenger engines, 204; goods engines, 194; royal saloon carriages, 2; first-class, 216; composite, 100; second-class, 273; third-class, 157; passenger luggage vans and brake, parcel and mail vans, 82; carriage trucks, 227; horse boxes, 121; open goods waggons and cattle trucks, 1,104; covered goods waggons, 1,946; coal, coke, and ballast trucks, 4,097; timber trucks, 184; goods brake vans, 55; and furniture vans, 18. The mileage worked is returned at 466, and the earnings of the past half-year were £852,947 against £847,452 in the corresponding period of 1857. The total net balance was £524,246 in past half-year, and £508,188 in the corresponding period of 1857, a reduction of nearly £11,000 having been effected in the working expenses. The expenditure on capital account has now reached a total of £23,237,554.——The London and South Western Company's report states that the net revenue for the half-year, after deducting interest on loans and all other preferential charges, is £202,480; and this sum enables the directors to declare a dividend at the rate of 5½ per cent. per annum. Considerable progress is stated to have been made in providing the additional stock necessary for working new lines about to be completed. Before the close of 1859 the Company will be working, including the Portsmouth line already opened, 120 miles of additional railway. With regard to the permanent way, a further portion of the main line has been renewed at an expense of £10,553 charged against revenue. The increased mileage run and the additional trains required in connection with the new lines is expected to create a considerable increase in the wear and tear on the old line. The doubling of the Southampton and Dorchester line for the 36 miles from Southampton to Wimbourne is completed, and the contractor is proceeding rapidly with the works on the Exeter extension. The station works at Salisbury at the junction with the Salisbury and Yeovil have been somewhat delayed; but the first portion of that line to Gillingham will be ready for opening in the spring. The new line from Wimbledon to Epsom which the Company have agreed to work will be opened—at least the board are so informed by the engineer—on the 1st of March. The parliamentary campaign, so far as this Company is concerned, threatens to be a serious one—the great railway evil.——The offer of Mr. W. Bryant to present to Plymouth six drinking fountains and three drinking troughs has been gratefully accepted by the town council.——The supply of water to Plymouth has been discussed at considerable length by the town council. It was estimated by the late surveyor, Mr. Bampton, that the quantity of water supplied by the corporation for domestic consumption and for trade and manufacturing purposes conjointly, amounted on an average to about 2,000,000 gallons *per diem*; and he considered that domestic supplies consumed one-third, while the remaining third represented the consumption in trade and manufactories. In the opinion of the present surveyor the estimate of this latter quantity is not exaggerated. The rental for the present year gives £4,093 as the sum paid by domestic consumers, and only £517 for trade and manufacturing purposes. The council have expressed their approval of a system of equalising the charges as between the manufacturers, recommending the water committee at the same time to confer with a deputation of manufacturers as to the scale of rates which should be fixed.——The *James Watt*, 91, screw, has been ordered to be brought forward and fitted for the first division of the steam ordinary. The Admiralty have ordered the *Supply* store-ship to be fitted with Cunningham's patent topsail; this is the second ship in the navy to which the invention has been applied. The *Atlas*, 91, one of the new screw steamers of the line ordered to be built at Chatham, will be launched during the present year, and will be attached to the Channel squadron. A large stone dock constructed at Chatham is now ready for the reception of any line-of-battle ship requiring to be fitted. The channel at the entrance to the basin has been considerably deepened, and the largest ship in the service could now be floated in for fitting or repairs.——It is reported that the Government have resolved to expend a considerable sum for the purpose of making St. Ives a harbour of refuge; but seeing that the commissioners appointed to consider the whole subject have not yet made their report, the statement appears premature. It is stated that something is also to be done at Dawlish.

NOTES FROM THE EASTERN DISTRICTS.

[FROM OUR OWN CORRESPONDENT.]

Water Supply of Chelmsford—Lincoln Mechanics' Institution and "Franklin Monument"—Oxford Middle Class Examinations—Boiler Explosion near Stamford—The Dams in the Nene: Odd Proceedings—Railway Materials for New South Wales.

THERE has been some more talking at Chelmsford anent the water supply of that pleasant little town. At a meeting of the Local Board of Health, a day or two since, the surveyor (Mr. Chancellor) stated that he was still collecting information on the subject. With respect to one proposed source of supply, the railway lake, Mr. Bruff, C.E., had intimated to him his belief that there were not any very powerful springs there; but he would push the inquiry to the contractors for the line. Mr. Bruff had also informed him that at Colchester some deep borings were made into chalk with little success, and it was proposed to leave off; but by his advice the parties went on, and after another 50 feet came to a spring from which an abundant supply of water was obtained. In another case, a person had bored 1,100 feet without obtaining water. One member of the local board observed that he thought the present water supply was not properly economised. The expense of the proposed works was roughly stated at £5,000 for a population of some 8,000. Eventually the whole subject was referred to the sanitary committee of the board, who were directed to make further inquiries.——At Lincoln a movement has been a long time on hand with a view to the establishment of a museum in honour of the late Sir John Franklin; and a considerable sum has been subscribed for the object. It has just been determined that the amount shall be applied conjointly with certain funds contributed for the establishment of a Lincoln and Lincolnshire Mechanics' Institute in Lincoln, so that one good building may be erected and used for the two institutions, which are to be called the "Lincoln and Lincolnshire Mechanics' Institute and Franklin Monument." A handsome building is to be erected in a convenient part of Lincoln.——Ipswich has been selected by the University of Oxford as the centre for the eastern district of the Local Middle-Class Examinations, which will commence in several of the provincial towns about the middle of June. A complaint was expressed at a recent meeting on the subject that the examination papers were not more closely connected with agriculture and the useful arts, the most important matters to which the middle-classes can devote their attention.——There has been a bad boiler explosion at Ryhall, near Stamford, two persons being killed and several others injured. The explosion took place at the works of Mr. R. Downes, plough maker. The jury at the inquest attributed the deaths to accident. Mr. Morley, an owner of portable agricultural engines, was among the witnesses examined, and stated that he had looked over the wreck of the engine, boiler, &c. The flue and chimney were blown away, and in his opinion the engine had been worked at too high a pressure, as he found the spring balance standing at 49, when, in his judgment, it should not have been more than 25. At the latter pressure the engine did its work well. He could not form any opinion as to the supply of water at the time of the accident. The boiler when in use ought to have been cleaned out at least once a month. Water had of late been muddy, and more might have accumulated during the last fortnight than for six weeks previously. The plates of the boiler were defective. He had repeatedly cautioned Mr. Downes against working the engine at too high a pressure—the last time, 23 hours before the accident.——It was intimated under this head last week that the Wisbeach magistrates had directed the dam placed in the River Nene at Waldersea to be removed (at the instance of the Wisbeach Town Council). Some odd proceedings have since taken place. An hour had scarcely elapsed from the time the magistrates signed the order, when a party provided with suitable tools proceeded to Waldersea to demolish the dam, although they were not acting with the official sanction of the Wisbeach Council, who were restrained by an injunction from the Court of Chancery. The posse was not less than 120 strong, and an impression was soon made upon the dam, which stood upon more than 100 very strong piles, braced together by massive cross beams, &c. Before the work of demolition was completed, the Mayor of Wisbeach, accompanied by the town clerk, went down to the spot and informed the men that they were acting upon their own responsibility and without the sanction of the council. This had the effect of stopping matters for a time; but the men afterwards returned to the dam, and the work of destruction was pushed on. An attack was subsequently made upon the other dam in the river at Guyburn.——A Lincolnshire firm has recently sent out some railway materials for use in New South Wales.

METAL AND COAL TRADES, &c.

[FROM OUR OWN CORRESPONDENT.]

General Condition of the Iron Trade: How Affected by the Emperor's Speech—The South Staffordshire Iron and Coal Trade: The Colliers' Movement—The Progress of the Trade in the North—Glasgow Pig Iron—The South Wales Trade—The Iron and Coal Trades of Yorkshire, Derbyshire, and Lancashire—Birmingham and Wolverhampton Trades—Sheffield Trade—Metals—Iron Ship-Building Trade—Glass Makers' Dispute—The Supply of Wool.

THE iron trade has not experienced any improvement upon its conditions at the date of our last report. Scarcely sufficient time has elapsed since the 7th of February in Paris to show what effect the undignified compound of egotism and mystification to which the world was treated on that day, will have upon the trade. By the ironmasters generally the expectations are but faint of the speech doing them much service—a want of confidence in the transparent truthfulness of the speaker being all but universal.

The different mills and forges in South Staffordshire are in fair operation, and those manufacturing first-class iron are in many instances producing more finished iron than usual. There is not much doing in pig iron, owing to the large contracts which were entered into about six weeks ago. A considerable number of blast furnaces are being prepared to be blown in. The coal trade is not quite so brisk as it was, but prices are well supported. A few of the colliers west of Dudley gave notice a week ago for a rise of wages, but have since withdrawn it. The colliers on the east side of Dudley are still agitating the question of an advance, but it is not likely to be successful in the present position of the trade. Certain of them, however, gave notice for a rise of 6d. a day last Saturday evening.

The iron trade of the north is in an active state; an excellent trade being done in rails in particular. This district is being fast developed. Mr. Richard Hoyle, of Newcastle-upon-Tyne, says:—"The number of furnaces available for smelting the ore of this district, comprising those of Cleveland, Durham, and Northumberland, are 87, the majority of which have been erected within the last eight years. Of these 73 are now in blast, and 14 out. Five more furnaces are in course of construction, and will, it is expected, be in operation shortly. The average number of furnaces in blast throughout the year has not exceeded 58; and at a minimum production of 170 tons of pig-iron per week from each furnace, the total produce of the year may be estimated at 512,720 tons. Much of this make is consumed in the district, and a considerable portion is sent into Yorkshire and Lanchshire. In Newcastle, local iron has partly displaced the Scotch, but in the other districts the excess of consumption has absorbed a large part of the Cleveland iron; whilst it has also maintained the consumption of Scotch and other pigs at about the usual rate. There are likewise large and increasing exportations to the continent, and the South of England affords another market in which Cleveland successfully competes with Scotch and other iron."

In Glasgow pigs continue to recede. On Tuesday the market was nothing doing. Shipments this week, 6,585 tons; corresponding week last year, 8,689.

In the iron and coal trades of Monmouthshire and South Wales there is an increased firmness, several good orders have been received for home and for foreign consumption. Railway iron continues to be in steady demand, and French commissions are now in hand at several works. There is no doubt that the present large demand for South Wales coal will be even increased, as there is now a manifest preference for it in the Government navy, as is evinced by the invitations for tenders from South Wales masters noticed in the list of open contracts in another column of this number of the MECHANICS' MAGAZINE.

Digitized by Google

The position of the iron trade in Yorkshire, Derby-hire, and Lanca-hire has been such as to indicate a general improvement. All the makers of the better description of malleable iron are fully employed. The coal trade is very good, a large number of orders have been given out for the London market. Rates are firm.

In Birmingham, where, contrary to expectation, the trade was getting duller, the speech of Napoleon III. has done and is expected to do but little in the way of improvement, until it shall be seen that actual preparations for war have ceased to be made by the French Government.

The Wolverhampton trades follow suit with Birmingham. The lock trade is tolerably good, with reasonable prospects of a further improvement. The workmen employed in the plate lock branch have issued a notice to their masters that they will not work at present prices after the 5th of March.

In reference to the trade of Sheffield, we learn there are some good foreign orders in the town. For cutlery, there is a fair demand. The file trade is slowly improving. Some houses in the steel trade continue slack, but many are pretty well employed. The rolling mills are nearly all at full work. The general trade is not in a flourishing condition; but there are evidences of a gradual change for the b tter. Compared with the state of affairs a year ago, there is a very marked improvement. Metals, copper, and tin, remain unaltered in price.

We learn from the circular of Messrs. Alfred Brett and Co., that the first month in 1859 has terminated with improved inquiries for steam ship property, both for purchase and hire. During a protracted period the coasting trade alone offered the most obtainable employment for steam vessels; and now, whilst the demand is increa-ing, it also begins to extend to foreign stations. Of the largest class of screw steamers, however, many are being laid up for want of remunerative freights, in addition to those already on the look-out for charters. A few shipbuilders have entered into contracts for new steamers; but the majority of building establishments are not desirous of immediate engagements. Several sales of moderate-sized screw steamers were effected in January, and the tone of the market for this description of property is more hopeful than it has been.

The glass-makers' dispute has assumed another phase. The Association of Flint-Glass Manufacturers have met in Birmingham, and passed the following resolutions—"That the Associated Manufacturers, earnestly desirous to terminate the present disputes, will receive a deputation of twelve workmen, on the 15th inst., at 12 o'clock, at the Crewe Arms Hotel, Crewe: but, if all obnoxious interference with their just rights as employers be not there or then withdrawn, they hereby adjourn to Tuesday, the 3rd of May."

The Bradford Chamber of Commerce has resolved to direct its attention to the encouragement of the growth of long and combing wool, and that a separate fund be contributed to carry the object into operation. The Wool Supply Association may now be considered as fairly launched.

NOTES FROM SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

New Screw Steamer for the Bengal Pilot Service—Glasgow Import Dues—Customs Receipts at Glasgow, Greenock, and Port Glasgow—Steam Navigation from Leith—Miners' Hours of Labour—The Pig Iron Trade: Prices and Shipments—The Coal Trade: Prices—The Western Bank of Scotland—The Vacant Situation of Engineer to the Clyde Navigation Trust—Scottish Railway Traffic.

MESSRS. WILLIAM DENNY and Brothers have contracted with the Government to build a screw steamer for the Bengal Pilot service, the machinery to be constructed by Messrs. Tullock and Denny.——A respectably signed memorial has been addressed to the trustees of the Clyde Navigation, urging that the existing import dues on direct foreign produce at the harbour of Glasgow are proving too excessive for the welfare of the port.——The Customs' revenue collected at Glasgow, Greenock, and Port Glasgow during the past month of January contrasts favourably with the amount received in the corresponding period of 1858. At Glasgow there was an increase of £2,720; at Greenock an increase of £6,085; and at Port Glasgow an increase of £457.——Steam communication has been resumed between Rotterdam and Leith, from which port steamers also run to Hamburg.——The miners of the Fifeshire collieries are making an effort to reduce their hours of labour to eight daily, or as near eight as possible. A conference is to be held next week at Glasgow.——The pig iron trade has been rather flat, but a fair business has been done at slightly reduced prices.——Coals have been rather dull of late, but prices have remained without change.——A lengthy report has been published by the liquidators of that disastrous undertaking, the Western Bank of Scotland. It seems that the total obligations of the bank at the date of its suspension, Nov. 9, 1857, amounted to £8,911,942; on the 1st of February, 1858, when the liquidation commenced, to £6,351,000; and at the present time to £1,770,000. There are at the credit of the liquidator's funds to the amount of £474,000, leaving a balance of £1,296,000 still to be provided for from unrealised assets and arrears of calls. From the prompt manner in which the two calls of £25 and £100 per share were met, and the improved position of the company's affairs, it is not expected that any further calls will require to be made.——Some time since Mr. Ure, engineer to the River Clyde Navigation Trust, resigned his appointment, proceeding to a similar situation on the Tyne. Thirty-two applications have been made for the vacant office, and of these five have been selected for the decision of the trustees. The five gentlemen thus selected are Mr. Charles Owen, Mr. T. Ormiston, Mr. A. Duncan, Mr. D. M'Call, and Mr. T. C. Gregory. The election is to take place on the 15th inst.——The traffic receipts of the twelve principal railway lines in Scotland, extending over 1,087 miles, were last week £13,267, or £2,209 more than the receipts of the corresponding week of last year. The only case in which a decrease occurred was the Dundee and Arbroath. As the state of railway traffic is now regarded as some indication of the condition of trade, the figures just quoted are satisfactory.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated November 2, 1858.

2438. M. A. F. Mennons, of Paris. An improved system of railway brakes. A communication from C. Arnoux, of Paris.

Dated December 1, 1858.

2740. R. Laming, of Hayward's-heath. Improvements in purifying gas, and in turning sulphuretted hydrogen, carbonic acid and ammonia, or their compounds, to profitable account.

Dated December 27, 1858.

2962. F. W. Turner, of Swansea, Mechanical Engineer. Improvements in steam-engines, condensers, and steam-boilers, and in promoting combustion in the furnaces of the same.

Dated December 28, 1858.

2968. A. Lyons, of Finsbury. Improvements in travelling bags.

Dated January 1, 1859.

8. J. Walkland, of Sheffield, Silver-piercer. An apparatus for lighting cigars and tobacco.

18. I. Wood, of Charing Cross. Improvements in cutting and finishing corks, and in machinery used for such purposes. A communication from H. F. Cox and A. Miller, of New York.

Dated January 13, 1859.

106. W. Bennetts, of Tuckingmill, Cornwall, Workman. Improvements in mechanism used for preventing accidents when raising or lowering skips, baskets, or apparatus, particularly applicable to mines.

117. W. Wilson, of Newcastle-on-Tyne, Hat Manufacturer. Improvements in machinery for felting bodies of hats and bonnets. A communication from J. S. Taylor.

Dated January 15, 1859.

123. J. Eccles, of Blackburn, Cotton Manufacturer. Improvements in the manufacture of articles from clay earths for building purposes, as substitutes for such articles as are usually formed of stone and other materials.

130. P. A. Viette, of Faubourg de Schaerbeck, near Brussels. Certain inks applicable for engraving and lithographic purposes.

132. R. Mushet, of Coleford, Metallurgist. Improvements in the manufacture of cast steel.

134. R. Mushet, of Coleford, Metallurgist. An improvement or improvements in the manufacture of cast steel.

Dated January 17, 1859.

136. T. Edwards, of Liverpool, Gas Engineer. Improvements applicable to letter-boxes and other like receptacles.

138. E. T. Hughes, of Chancery-lane. Improvements in machinery or apparatus for sowing seed. A communication from C. Beure and E. Barret.

140. S. T. Cooper, of Upper Clapton, Gentleman. Improvements in the use and application of artificial light.

142. E. Brooks, of Edward-st, Dorset-sq., Locksmith. Improvements in locks.

144. G. and J. Collier, of Halifax. Improvements in means or apparatus for washing and drying wool and other fibres, part of which improvements is also applicable for other purposes, where steam, hot water, or other fluids are required to be conveyed under pressure through movable connections.

Dated January 18, 1859.

146. J. Luis, of Welbeck-st. A new machine for putting on, equalizing, and drying the colours on paper for hangings, bookbinding, boarding, and fancy paper of every description. A communication from J. P. Faure, of Paris.

147. W. Newman, of Aston, near Birmingham, Brass-founder. New or improved furniture for window and other blinds.

148. J. Foster, of Lancaster, Corn Merchant. Certain improvements in machinery or apparatus called "spinning frames" and "roving frames" employed for spinning and roving flax, tow, hemp, jute, and other fibrous substances.

149. G. Hamilton, of Liverpool, Professor of Chemistry. Improvements in treating resin and resinous substances to obtain products therefrom, and in treating the products obtained from resin and resinous substances.

150. H. Gallon, J. H. Bean, and S. Lumb, of Leeds, Machine Makers. Improvements in machinery for slotting, morticeing, tennoning, and cutting wood, iron, and other substances.

151. C. D. Archibald, of Rusland Hall, Lancaster, Esquire. Generating force. A communication from H. M. Paine, of Worcester, Mass.

152. R. A. Brooman, of 166 Fleet-st., Patent Agent. An improved silk thread, and a new fabric made entirely or partially from the same. A communication from C. Depouilly, sen., of Paris.

153. R. Garrett, jun., of Saxmundham, and J. Kerridge, Foreman to Garrett and Sons. An improved arrangement of combined thrashing and dressing machines.

154. J. Fawcett, of Kingston-upon-Hull, Merchant. An improved preparation of food for cattle and horses.

155. R. Bradley and W. Craven, of Wakefield, Engineers. Improvements in machinery or apparatus for manufacturing bricks, tiles, and other similar articles.

156. W. Trotter, of South Acomb, Northumberland, Farmer. Improvements in reaping machines.

157. J. H. Johnson, of Lincoln's-inn-fields. Improvements in air pistols and guns. A communication from J. L. L. Daimé, of Paris.

Dated January 19, 1859.

159. W. A. F. Powell, of Bristol, Potter. Improvements in stopping or closing jars and bottles.

161. T. Clarke, of Derby, Moulder. Improvements in the manufacture of core barrels for pipes or columns used either for railway pipes or columns, or for water pipes or sewerage pipes.

162. E. T. Hughes, of Chancery-lane. Improvements in machinery or apparatus for measuring and sorting silk and other textile materials. A communication from J. Veyrin, of Lyons.

163. J. Whitehead, of Halifax, Wire Maker. Improvements in the means or machinery for the manufacture of "purled" wire.

164. E. Stevens, of Patriot-row, Cambridge-road. An improved cooking utensil.

165. T. A. Evans, of Bayswater, and W. J. H. Rodd, of Islington, Artist. A new method of advertising.

166. W. Poupard, of Blackfriars-road, Engineer. An improved wheel-skid or shoe.

167. J. H. Johnson, of Lincoln's-inn-fields. Certain improvements in the manufacture or production of lasts, boot-trees, and clogs, and in the machinery and apparatus employed in the production of such articles. A communication from J. Mathieu, of Paris.

Dated January 20, 1859.

170. J. C. Reid, of Liverpool, Master Mariner, and W. Milner, of the same place, Manufacturer. Certain improvements in the construction of ships and vessels.

171. H. Hilliard and T. Chapman, of Glasgow. Improvements in table-knives, and in table-knife sharpeners.

172. A. Lindo, of Batignolles, France, Chemist. Improvements in manufacturing soap.

173. W. Woofe, of Gloucester, Agriculturalist. Improvements in implements for ploughing, tilling, and paring land.

174. E. T. Hughes, of Chancery-lane. Improvements for preventing incrustation in steam boilers or other vessels. A communication from Von Langen of Berlin.

176. S. Phillips, of Moseley, Worcester, Gentleman. Improvements in sliding sashes, shutters, or doors.

177. W. E. Newton, of Chancery-lane. Improved apparatus for measuring water and other liquids. A communication from A. Nobel, of Paris.

178. T. Greenwood, J. Batley, and J. Dockray, of Leeds, Machinists. Improved machinery for converting hemp and flax fibres into yarn, twine, ropes, and cordage.

179. J. Bent, of Birmingham, Military Ornament Maker. Certain improvements in clasps or fastenings, applicable for belts, garters, and other purposes.

180. J. Shanks, of Arbroath, Machinist. Improvements in mowing machines.

181. J. L. Clark, of Haverstock-hill, and J. Muirhead, of Gloucester-road, Regent's-park. Improvements in electric telegraphs, and in the apparatus used in working the same.

182. H. Sagar, of Broughton, near Manchester, Bleacher, and A. Schultz, of Paris, Chemist. Improvements in producing pink shades on cotton fabrics or yarns.

Dated January 21, 1859.

183. T. Richardson, of Newcastle-on-Tyne. Improvements in the manufacture of manure.

184. S. Osler, of Great Yarmouth, and J. B. Balcombe, of Brixton, Gentleman. Improvements in apparatus for treating fish, so as to adapt it for manure, and in using the same alone or in combination with super-phosphate of lime or other phosphates.

185. L. Le Prince, of Regent-st., Bootmaker. The improvement of ladies' boots and shoes, called the cameleon boot and the cameleon shoe.

186. G. B. Harkes, of Southwark. An improved machine for washing, wringing, and mangling.

187. G. Ellis, of Pentonville, Merchant. The improvement of muffs, to be called the patent reticule muff.

188. J. Hick and W. Hargreaves, of Bolton-le-Moors, Engineers. Improvements in the construction of steam boilers.

189. R. Howell, of Smethwick, Stafford, Gas Fitter, and R. J. Willder, of Birmingham, Hatter. An improvement or improvements in taps or stop cocks.

191. W. Wells, of Greetland, near Halifax, Cotton Spinner. Improvements in machinery or apparatus employed in spinning and twisting cotton, and other fibrous substances.

192. A. Davenport, of Birmingham, Gas Purifier Maker. An improved regulating burner for gas. A communication from H. Woodward, of New York.

193. J. Childs, of Putney. An improvement in applying heat in the manufacture of artificial gums and teeth, and other articles composed of India rubber, or gutta percha, combined with sulphur.

194. J. H. Hume, of Broughty Ferry, Forfar, Baker. Improvements in warming apparatus for the feet.

195. A. J. A. Gautier, J. G. Dumay and J. T. Persin, of Paris, Gentlemen. An improved manure.

197. J. Newman, of Birmingham. Improvements in the manufacture of chains.

198. B. Lauth, of Surrey-st., Westminster, Mechanician. An improved mode of, and improved machinery for, rolling plates, bars, rods, and shafts.

199. J. Edwards, of Aldermanbury. Improvements in the manufacture of buckles.

Dated January 24, 1859.

201. D. Moseley, of Ardwick, Manchester, Manufacturer. Improvements in the manufacture of india rubber thread.

203. E. Dorsett, of Old Broad-st., Tar Distiller, and J. B. Blythe, of Neweross, Merchant. Improvements in the distillation of oil from coal tar, and in apparatus for preserving timber therewith.

205. W. E. Newton, of Chancery-lane. Improved machinery for cutting files. A communication from M. D. Whipple.

207. C. Sharps, of Philadelphia, Manufacturer. Improvements in breech-loading repeating fire-arms.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 1319, 1333, 1335, 1358.

BOILERS AND THEIR FURNACES, 1301, 1329, 1334, 1337, 1351.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1302, 1310, 1346.

SHIPS AND BOATS, including their fittings, 1331, 1352, 1359.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1300, 1305, 1315, 1316.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1313, 1323, 1326, 1331, 1336, 1338, 1345, 1349, 1350, 1360.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*

LIGHTING, HEATING, AND VENTILATING, 1308, 1309, 1311, 1324, 1328, 1344, 1347, 1348.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1312, 1327, 1340, 1344.

METALS, including apparatus for their manufacture, 1343, 1346, 1354.

CHEMISTRY AND PHOTOGRAPHY, 1322.

ELECTRICAL APPARATUS, *None.*

WARFARE, 1306, 1321, 1361.

LETTER PRESS PRINTING &c., 1341.

MISCELLANEOUS, 1299, 1303, 1304, 1305, 1307, 1314, 1317, 1318, 1320, 1325, 1330, 1332, 1334, 1338, 1339, 1342, 1353, 1355, 1356, 1357, 1358.

1299. S. LEES. *Improvements in the manufacture of tan or tanning, and in tanning hides to make leather.* Dated June 9, 1858.

This invention consists in treating the oils obtained by the distillation of coals or other bituminous, earthy, oily substances with strong sulphuric acid, until a black carbonaceous pitchy substance is formed. The process is facilitated by steam passing through pipes placed within the vat containing the oil and acid, which are agitated until the carbonaceous pitchy substance is obtained; and any undecomposed oil found upon the surface must be taken therefrom and may be used for lubricating machinery. The steam is then shut off, and the inventor adds by degrees strong nitric acid, stirring the whole until it boils and becomes a dark brown pitchy substance. He then adds liquid ammonia or gas tar-water, or other alkali, until it takes up the remaining acids. During this process steam must be applied to keep the pitchy substance in a liquid state, care being taken not to add too much alkali, so as not to dissolve the said substance, which he calls mineral tar. This is then dissolved in common soda, potash, or alkaline lyes of any specific gravity, according to the quality or thickness of the skins to be tanned. These skins are first prepared in lime as usual, and then steeped in a solution of the mineral tar above described. When they have sufficiently imbibed the tanning, they are taken out and put into a solution of alum or other metallic salts, until the tanning becomes fixed, and the hides or skins converted into leather. *Patent abandoned.*

1300. E. T. HUGHES. *Improvements in machinery or apparatus for sowing grain.* Dated June 9, 1858.

This specification is mainly a description of drawings. *Patent completed*

1301. E. C. GRIMSHAW. *Improvements in furnaces and steam boilers.* Dated June 9, 1858.

These improvements consist in combining stoves used in hat-finishing, or for similar purposes, with boilers, so as to make the furnace capable of heating irons, and converting water into steam. These arrangements may be used for a variety of purposes with much economy of fuel. *Patent completed.*

1302. W. A. GILBEE. *Improvements in the construction of railway wheels.* (A communication.) Dated June 9, 1858.

This invention relates to solid railway wheels, and its object is to reduce the iron, time, and labour expended in their construction. 1, the inventor makes the felloe and nave separately, and employs stamped wrought iron plates placed against each other to strengthen the same. When the parts are put together, the whole are heated and welded (by a hammer or otherwise,) between dies. 2, in some cases, before the parts are united, the nave is forged in a die, and the plates are placed against annular shoulders made on both sides of the nave, and then all the parts are placed between dies. The projecting parts of the nave are afterwards brought down. The usual tyre is placed over the felloe. The plates mentioned may be curved, and attached to the nave and felloe, and be united by bolts or rivets. *Patent abandoned.*

1303. C. F. VANSEROT. *An apparatus for measuring and registering the flow of liquids.* (A communication.) Dated June 9, 1858.

Here two cylinders are placed side by side, and two connected balance-beams are placed one above and one below them. A pipe open at both ends ascends to a certain height in the centre of the cylinders. The liquid is admitted to the cylinders alternately, until it flows over and down the pipe into a cup below it, resting on the lower balance beam. A counterpoise above the other cylinder is thus raised, and the balance beams are forced down. This movement raises the rod of a valve at the bottom of the cylinder, and the liquid which it contained, as well as that in the cup, is then discharged. On one end of the axle of the upper balance beam is a crank, the rod of which moves wheelwork outside of the apparatus, thus actuating the hands of indexes indicating the number of the strokes—at each of which a given weight (and therefore quantity) of water is passed through the apparatus. *Patent abandoned.*

1304. J. EASTERBROOK. *An improvement in ratchet braces.* Dated June 9, 1858.

This invention consists in letting into the bow in which the rachet lever is made to terminate, a toothed spherical-sided wheel which is acted upon by a spring or other paul let into the lever. The wheel is retained in the bow by a collar secured by screws. The brace thus formed, while it possesses all the advantages of an ordinary ratchet brace, can be used in positions where a brace with a straight-sided ratchet wheel would be wholly inapplicable. *Patent completed.*

1305. P. DUMONT. *Improved implements for distributing or applying powder.* Dated June 9, 1858.

These implements are principally for destroying vermin, but may be used for many other purposes. They consist of self-distending india-rubber balls (with or without handles), having each a small tube or jet, which may be removed when the powder is to be introduced. By compressing the ball smartly the powder may be blown out through the tube upon plants, &c. *Patent completed.*

1306. T. W. G. TREEBY. *Improvements in revolving fire-arms and cannon and cartridges.* Dated June 9, 1858.

This invention relates to a former patent, dated 10th January, 1856. According to the present improvements the chains are hinged to the chambers by the side of the chambers (and not in the centre), and the endless chain revolves over two pulleys or drums (instead of one), and is made tight by them. The inventor also makes the main barrel send the charge home in the chamber by a screw and nut with lever, or lever and cam; thus doing away with the ramrod. The cartridge is as usual, but, in the end where the powder is put, he places a metal ring on the end of a mandril hollowed out to receive it. The end of the cartridge is then turned into the ring, and a percussion cap driven in with the hollow part towards the outside, thus completely securing the cap in the centre and fastening the end of the cartridge. The cartridge is charged with powder and ball in the usual way. The strikers or plungers are attached to each chamber fastened in the breech end, and revolve with the chain of chambers, and at the end of the iron frame he places a hammer, attached to the lock by a pin and a cam slotted in the lock. When the hammer is pulled, it strikes the plunger and explodes the cap, the ring and cap passing out with the charge. The plunger is therefore not injured by continual firing. *Patent abandoned.*

1307. H. ROLLINSON. *An artificial fuel.* Dated June 9, 1858.

This invention consists in using combinations of coal, pitch, breese, with or without ashes, broken or crushed coke, or sawdust, to which may be added Stockholm pitch, resin, or other substances capable of burning. These are heated, moulded into blocks, and pressed if required. *Patent completed.*

1308. T. ROBINSON and H. OGDEN. *Improvements in safety lamps, and in apparatus connected therewith.* Dated June 9, 1858.

In attaching the gauge to the lamp so that it cannot be removed by any apparatus which the miner usually has at his disposal, the inventor employs, first, two or more fastenings which must be held simultaneously to allow the gauze to be removed; secondly, keys acting by screw threads for unlocking, whether one or more fastenings be employed; thirdly, an apparatus for unlocking, whereby two or more keys are made to act simultaneously. Enamelled metal reflectors for safety lamps are also used by him. *Patent completed.*

1309. J. ROBERTS. *An improved construction of reflector or cover for gas burners.* Dated June 9, 1858.

The chief object of this invention is to prevent the accumulation of heat in apartments arising from the combustion of gas. For this purpose the inventor applies to the metallic reflectors used with gas burners, or to the covers for intercepting the smoke of the gas flame, a water chamber, which, being close to the flame, will take up a great portion of the heat generated, and by transmitting it to the water, give off an aqueous vapour that will keep down the temperature. Standing up over the central hole in the reflector is a tube with a closed end. Surrounding this tube is a larger and longer one. These tubes are securely brazed to the upper side of the metallic disc reflector, and form an annular water chamber, over the inner periphery of which the heated gases play, thereby evaporating the water. In cases where a reflector is not required, the suspended cover for collecting the smoke may be made with an annular water chamber. *Patent abandoned.*

1310. C. CAMMELL. *Improvements in railway buffers.* Dated June 9, 1858.

The inventor so arranges the parts of buffers that the springs shall not be liable to be damaged by undue compression when suddenly collapsed. To this end the helical spring of the buffer head is enclosed in a cylindrical case, which is attached either to the end framing, or to the buffer head, and is long enough to prevent the spring collapsing to such an extent as to drive the coils against each other. By so constructing the spring case the edge of the latter will, when the buffer is collapsed, be driven against the solid end frame, or against the buffer head, and will thereby prevent the coils of the spring from being driven against each other. The same object may be effected by placing a strong rod, or cylinder, within the coiled spring, and causing it to work up and down within the spring, or the spring to work thereon. This rod may be attached either to the end framing, or the buffer head. Sometimes the inventor proposes to place between the metallic coils of the spring rings of a yielding material, to prevent the coils from being brought into contact. A cushion may also be used to receive the pressure of the cylindrical case. *Patent completed.*

1311. J. ROBERTS. *An improved construction of stove.* Dated June 9, 1858.

The object here is to construct a stove in which the fuel may burn for a considerable time, giving off an equable

Digitized by Google

heat without requiring attention. To this end is employed a combination of well-known parts, slightly modified in construction, whereby the fuel is burnt from the top downwards. This combination is not described by the inventor apart from his drawings. *Patent completed.*

1312. G. CASTLE. *Ventilating women's stays by means of perforation.* Dated June 10, 1858.

This invention consists in perforating stays to afford escape to the heat and moisture of the wearer's body. *Patent completed.*

1313. T. W. MELLOR and W. JAMIESON. *Certain improvements in looms for weaving figured fabrics.* Dated June 0, 1858.

This invention consists in certain alterations and additions to looms for weaving figured fabrics, which are mounted either with treddles or harness, and are operated upon in one direction by springs or weights. The improvements relate to that part of the apparatus by which the treddles or harness are acted upon in the contrary direction to the springs or weights, in order to form the *sheed* for the passage of the shuttle. These improvements are not described by the inventor apart from his drawings. *Patent completed.*

1314. J. LUIS. *An alembic wine examiner.* (A communication.) Dated June 10, 1858.

This specification is mainly a description of drawings. *Patent abandoned.*

1315. J. LUIS. *An improved thrashing machine.* (A communication.) Dated June 10, 1858.

This specification consists mainly of a description of drawings. *Patent completed.*

1316. J. LUIS. *An improved balance-beam thrashing machine.* (A communication.) Dated June 10, 1858.

This specification is mainly a description of drawings. *Patent abandoned.*

1317. J. LUIS. *An improved nose-bag for giving horses their oats, &c.* (A communication.) Dated June 10, 1858.

This bag is made of coarse thread canvas, the threads of which are close enough to prevent the oats from falling out, and open enough to permit the horse to breathe easily. The old mode of suspension is not altered. *Patent abandoned.*

1318. T. CHATWIN and C. TAYLOR. *Improvements in screw stocks.* Dated June 10, 1858.

The improved screw stocks contain three dies, one ordinarily stationary, and the other two capable of moving towards it when the screw is being cut, or when bolts of different diameters have to be screw-threaded. The patentees claim, 1, causing the moveable dies of a screw stock to advance, either by the advance of a screw-box upon the screwed handle of the stock, or the advance of a screw in the body of the stock. 2, causing the several dies of a screw stock to advance simultaneously by the use of a ring encircling the dies, the inclined inner face of the ring urging the dies forward when the ring is made to advance by a screwing motion into the body of the stock. *Patent completed.*

1319. J. S. CROSLAND. *Certain improvements in steam engines.* Dated June 10, 1858.

These consist, 1, in an improved combination of a high-pressure vibrating or oscillating engine as auxiliary or pusher, or to compound any other condensing steam engine whether marine or stationary. 2, in the application of a high-pressure double cylinder (horizontal) engine, "as auxiliary, &c.," as in first claim. 3, in an improved combination of a high-pressure single cylinder (horizontal) engine, "as auxiliary, &c.," as before. 4, in passing the supply and exhaust steam with concentric pipes through a single trunnion of a vibrating or oscillating cylinder, instead of through separate trunnions as heretofore. *Patent completed.*

1320. W. DAVIS. *Certain improvements in the tangs of awls, also in the mode of manufacturing awl-blades or similar articles, and likewise in the stocks or pads for holding the same.* Dated June 10, 1858.

1. Here improved tangs are formed of a uniform size, and may therefore be applied readily to any handle; they also make the awls, &c., stronger. 2, a new mode of giving form to the blades of awls is used. 3, the stocks or pads are connected to the handles by improved means, which are also applicable to surgical instruments, cork screws, &c. The inventor's drawings are referred to throughout the descriptive part of this specification. *Patent completed.*

1321. G. HALL. *Certain improvements in cartridges.* Dated June 10, 1858.

In order to load the gun by means of a cartridge, and yet arrange the powder, &c., in the barrel as if they had been poured from flasks, the inventor places his charge within a case so formed that it may be inserted in or fixed on the muzzle, and then the charge be rammed down by the ramrod, and the case afterwards removed, either to be re-charged or thrown away, according to its value. *Patent completed.*

1322. H. REYNOLDS. *An improved method of separating glycerine from saline and other substances.* Dated June 10, 1858.

This invention consists in blowing on or through spent soap lees a current of dry steam, at a temperature of about 408° Fahrenheit. The fluid may be first reduced by evaporation, and raised nearly to the boiling point by being passed through a heated still-like vessel, or by being heated in any other vessel. It is then passed into another vessel where it is met by a jet or jets of superheated steam, which raises it to the boiling point, and evaporates the glycerine, carrying the vapour upwards with it, and leaving the salts to deposit themselves in the vessel. Greater purity can be obtained by repeating the process. *Patent completed.*

1323. W. WILKINSON. *Certain new textile and other combined fabrics, and means of ornamenting fabrics and skins.* Dated June 10, 1858.

These fabrics are made by uniting by india-rubber solution, or other adhesive substance, two pieces of cloth, or cloth and silk, or two textile fabrics (ornamented on both sides, or not), and subsequently ornamented or not by embossing or otherwise, and with or without a central strengthening or foundation piece, or other textile fabric. The inventor also forms a new combined fabric by cementing a cut pile or other fabric to the back of leather, kid, and other skins, and making the solution used to unite the fabric to the skin porous by forming holes therein, that the finished fabric may be porous. He forms elastic stockings and bandages by uniting thicknesses of cotton, silk, or other web by india-rubber solution pierced with holes before being allowed to dry; or he causes a piece of india-rubber cloth pierced with numerous holes to adhere to webs of stocking fabric. The object is to produce elastic stockings and bandages porous throughout. The means of ornamenting fabrics, leather, and skins consist in the application thereon by adhesive matters of patterns and devices produced in similar materials, or in different materials to those upon which the ornament is to be applied, and in the same or different colours. The ornament may be ground flocks, or lace, or flowers produced in silk or cloth to imitate embroidery and otherwise. *Patent abandoned.*

1324. W. C. WILKINS. *Improvements in lighthouses.* Dated June 10, 1858.

Heretofore, when dioptric apparatus has been used in lighthouses, such apparatus has been combined with metallic reflectors. These improvements consist in combining spherical glass reflectors with dioptric apparatus. *Patent abandoned.*

1325. J. GEMMELL. *Improvements in the manufacture of starch.* Dated June 11, 1858.

In these improvements the material is steeped in water, and otherwise treated as usual. The coarser particles are then separated from the rest, and the strained product poured on to a runner, hitherto used for separating the starch from the "shines." The water is thus run off, and the whole of the amylaceous product precipitated upon the face of the "runner." The starch is now removed to be dried; thus the whole process is effected in one apparatus. The inclined planes or runners may be modified to suit the object in view, and may be arranged in series, so as to carry out the process continuously. By these means the yield of starch is made uniform, the ordinary waste being avoided, and time, labour, and plant economised. *Patent completed.*

1326. L. A. BIGELOW. *Improvements in sewing machines.* (A communication.) Dated June 11, 1858.

This invention was described at p. 620, of No. 1846 of the MECHANICS' MAGAZINE, for Dec. 25, 1858, a complete specification having been filed with the application. *Patent completed.*

1327. L. A. BIGELOW. *A new and improved machine for sweeping carpeted and other floors.* (A communication.) Dated June 11, 1858.

This invention consists of a box open at the bottom, in which are the brushes and machinery. It is drawn along the room by a handle, and the dust collected in two suitably placed dust-pans. The chief novelty is, that the brush is put in motion by a cogged or toothed wheel, on the axis of the wheel on which the apparatus rests. *Patent abandoned.*

1328. G. BARTHOLOMEW. *Improvements in that description of gas meters commonly called wet meters.* Dated June 11, 1858.

The object here is to secure uniformity in the measurement of gas, by keeping the surface of the water in the measuring compartments at the same level, although, by evaporation or otherwise, the water becomes diminished or increased in the case. The inventor claims the arranging wet or water gas meters so that the drum or measuring chambers acting on suitable index apparatus are made to float in the water or other fluid contained in a case or reservoir, whereby such drum or measuring chambers, whilst such meters are in action, are sustained at a uniform and determined line of immersion in such water or other fluid, whatever may be the height of the water or other fluid in such case or reservoir and unvarying measurement thereby obtained. *Patent completed.*

1329. W. E. NEWTON. *An improved apparatus for supplying boilers with water.* (A communication.) Dated June 11, 1858.

The objects here are, 1, to regulate the pumps to the requirements of the boiler. 2, to sound an alarum should the pumps cease to act. The only part which the patentee describes apart from his drawings is a combination of a feed apparatus controlled by expansion and contraction, with an expansion tell-tale placed below the lowest safe water level. *Patent completed.*

1330. S. CHEAVIN. *An improved preparation or combination of mineral substances, applicable for use as a pigment, cement, or mastic, or to be used either alone or in combination with other well-known materials for washing, scouring, cleansing, or bleaching purposes.* Dated June 11, 1858.

The substances here used are red ore, or hematite iron ore, in combination with the slag or scale left from the working of iron in iron works. These materials are pulverized and intimately mixed, and then are either combined with oil or turpentine, &c., to form a pigment, or are mixed with water to form a cement or mastic. The slag, &c., may also be combined with soap, &c., and employed for scouring, washing, or bleaching. *Patent completed.*

1331. L. F. LENIERE. *Improvements in treating hemp or tow for the caulking of ships and vessels, parts of which improvements are applicable to washing and cleansing textile articles or fabrics impregnated with greasy or oily matters, and in the apparatus connected therewith.* Dated June 11, 1858.

This invention consists, 1, in obtaining good oakum or a substitute superior to oakum, by submitting new hemp or tow to a bath of tar, in an apparatus suitably heated. 2, in the application of the composition and apparatus, slightly altered, to the cleansing of textile fabrics and substances impregnated with oily or fatty matters. *Patent completed.*

1332. G. W. HART. *Improvements in the manufacture of locks.* Dated June 11, 1858.

Here the bolt of the lock is made with a fixed stump on it, and two slots through it. There is one set of tumblers acted on by the key, and a detached tumbler by a cam put in motion by the key, or by the key itself. The bolt has at its upper edge a projection the back edge of which is inclined, corresponding with an incline on the front edge of a projection on the upper edge of the tumbler which is actuated by the cam. The tumbler, which is worked by the cam, has also a slot through it in which the stump on the bolt moves as the bolt is slid back, and such slot at its lowest part is longer than at its upper part. The back part of the tumbler which is worked by the cam has a projection at its upper edge, which rests against a fixed stop on the case of the lock, so that should it be attempted to push back the bolt it would by its upper projection come against the projection at the fore end of the detached tumbler and be resisted by it, and that by a fixed stump on the case. The tumblers actuated by the key move on an axis at their back ends, and the fore end of each is formed into a toothed sector, which takes into a pinion, on the axis of a disc having formed on its circumference a number of false notches and true notches or holes. The false notches are less deep than the true, and the tumbler which is worked by the cam has a tooth which, when the discs are turned correctly into position by the corresponding tumblers moved by the key, will fall into the true notches of all the tumblers. The discs have fixed guards around them, except opposite the place where the true notch is to be brought when the proper key is used. By these arrangements it will be seen that the key used must not only act correctly on the key tumblers, but by the cam it must also act correctly on the cam tumblers, consequently no tampering or prejudicial action can take place in respect to the bolt by pressing it back, as the bolt would be resisted going back unless the tumblers are first properly acted on. In some cases the inventor makes locks with rotating tumblers, *i.e.*, a series of discs with a number of false notches in the peripheries, true notches in each. Each disc is made with a hole for the key and a number of steps, one only being the true one for the key. The discs are surrounded by a ring having a projection for the key to act upon, and on this ring there is a pin which works in a slot in the sliding bolt. This ring is kept in position by the case of the lock, which is circular, and in the ring there is a sliding piece which is projected outwards by a spring, there being a recess in the case to receive the sliding piece. When the key turns the ring, an incline on the case acts on the sliding piece, and forces it into the true notches of the discs (which have been turned into position by the key,) and allows the key to be turned, and the bolt to be withdrawn; but if the discs have not been brought into such a position that the sliding piece enters the true notches, the sliding piece is prevented from being forced in, and in consequence the ring is prevented from being turned and the bolt from being shot. In some cases he applies two stumps to the bolt, one of which has teeth on its back surface, which, if the bolt be pushed when the tumblers are not properly placed, take into notches or teeth formed on the fore end of the tumblers. The tumblers, when properly placed by the key, allow the two stumps to pass through a longitudinal slit, there being also transverse slits to receive the stumps when the bolt is thrown or withdrawn *Patent completed.*

1333. G. T. BOUSFIELD. *Improvements in marine steam engines.* (A communication.) Dated June 11, 1858.

This invention was described at page 620, of No. 1846 of the MECHANICS' MAGAZINE for Dec. 25, 1858, a complete specification having been filed with the application. *Patent completed.*

1334. G. T. STIELER. *Improvements in the means for generating steam and economising fuel.* Dated June 12, 1858.

These improvements consist in the arrangement of one or more water spaces, bridges, or transverse tubes in the fire-boxes of locomotive or other tubular boilers, whereby the inventor is enabled to use a series of fire tiles of suitable form through which the products of combustion are conducted; and he also introduces a number of hollow stays into different parts of the fire-box, and through these a supply of atmospheric air is conveyed to the products of combustion. *Patent abandoned.*

1335. J. HALL. *An improvement in the slide valves of steam engines.* Dated June 12, 1858.

This invention consists of an alternate expansion valve, arranged to afford facility for cutting off the steam at any required part of the stroke. Being connected to a governor, so as to vary with the speed of the engine, it dispenses entirely with the necessity for a throttle valve. The slide valve is of the ordinary construction, with the addition of a steam port at each end. The ports are covered by flap valves lying on the top, and mounted upon levers vibrating upon a central fulcrum attached to the back of the valve. These flap valves are each furnished with a pin or friction roller, acted on by a fixed cam placed at each end of the throw of the slide valve. As the flap valves are raised by the cams, they are held by retaining levers (and acted upon by a spring) until the return of the slide valve brings these levers alternately against one or other of the two stop pins attached to slides. The flap valves are thus alternately raised and released, and falling by their own gravity shut off the steam. This can be done at any part of the stroke, as the slides which carry the stop pins are moveable, and so connected by a pinion and racks that as the speed of the engine varies, the stop pins are moved nearer to or farther from each other, and thus the amount of steam allowed to enter the cylinder is regulated. These slides move so easily that the governor acts upon them instantly, and consequently regulates the speed of the engine very quickly when the load is increased or decreased. *Patent completed.*

1336. W. CLARK. *Improvements in machinery for combing cotton and other fibrous materials.* (A communication.) Dated June 12, 1858.

The inventor claims nippers of any kind, for holding fibrous materials, of which one part at least turns on its axis, is of cylindrical form, and has a jerking or intermittent motion. He also claims certain new arrangements of gear for imparting motion to the nippers for combing

Digitized by Google

fibrous materials. He claims, too, the application of this machinery to the combing of all fibrous materials. The inventor refers to drawings throughout his description of the improvements. *Patent completed.*

1337. A GIBSON, J. POLLOCK, and J. MARTIN. *Improvements in the construction of steam-engine boilers and furnaces for effecting the prevention of smoke.* Dated June 12, 1858.

This relates to the introduction of air into furnaces by a peculiar application of an air-pump or pumps, or by atmospheric pressure through tubes. *Patent abandoned.*

1338. W. CLARK. *A new treatment or preparation of a vegetable product, and its application as a fibrous or textile material.* (A communication.) Dated June 12, 1858.

According to this invention the "nettle" is substituted for animal wool and silks either by using it alone, or in combination with animal silk or wool, and it is also dyed in all kinds of colours, which it takes perfectly. The method of preparation, after having boiled and removed the ligneous part from it, is the following:—1. For softening the plant, and completely bruising or breaking the ligneous parts which may still adhere to it, it is passed under an edge runner rolling on a horizontal stone, or is acted on by any similar means. 2. The inventor proceeds with the operations for obtaining the silk or wool, which differ according as it is wished to obtain one or other of these substances. If both are to be obtained, the plant is divided into two parts, and for the silk the fibres found in the core or heart are selected as being the finest and brightest. The remaining part of the vegetable is to be treated in the following manner, to produce the vegetable wool:—1. The substance should be combed like hemp. 2. After being well combed it is mixed, if required, with animal wool, cut to the same length as if by an instrument with teeth which tears the plant. 3. In this condition it is submitted to the action of a caustic lye, composed of salts of soda, about 15 lbs. to every 375 lbs. of vegetable, and 5 lbs. of a solution of lime, or one-third of the salt employed (or any other analogous chemical agent), which solution of lime is decanted and poured into the boiler containing the vegetable and lye. The latter should mark two degrees of the lye meter of Beaumé. It should boil two hours, then be withdrawn, and perfectly washed with running water, if possible. For drying it promptly, it is, by preference, poured into a dydro-extractor, and then spread in the open air, but any other system of drying may be employed. 4. When dry, the vegetable is placed in a vat of wood lined with lead, and in which several hours before has been placed a solution of chloride of lime, which should mark 1½ or 2 degrees of Beaume's concentrated acid matter. The bleaching is effected in two hours, after which the vegetable is withdrawn, washed till the last water used remains clear, placed into the drying apparatus, and afterwards spread in the open air till dry. 5. To give it, when bleached, all the suppleness it can acquire, it is passed into a bath of soap, then carefully washed and dried in the air. 6. The vegetable is now ready to be manufactured into wool or silk. For well separating it, it is passed through a devilling machine, and then into a spiked gig-mill if necessary. All the methods ordinarily employed for the manufacture of silk and wool may be used for that of this vegetable. *Patent completed.*

1339. A. V. NEWTON. *Improved machinery for cutting veneers.* (A communication.) Dated June 12, 1858.

This invention consists mainly in the use of two knives made to cut the veneer from opposite sides of the block of wood, each knife cutting one half the veneer, and making its cut in the same plane with the other knife, and parallel with the run of the grain. The veneer is thus little liable to be roughed or broken. To cut veneers from such woods as are commonly used, it should first be steamed, or softened by steam and hot water combined, but this is not required if the wood be soft or green. *Patent completed.*

1340. W. CLARK. *Improvements in curtain poles or rods.* (A communication.) Dated June 14, 1858.

This relates to the employment of grooved curtain poles, in the spiral grooves of which the curtain rings lie, being traversed ordinarily along the grooves, to or fro, as the pole is turned by cords passing over pulleys on them; and the invention comprises an improved means of arranging the curtains, by which the cords and pulleys are dispensed with. *Patent abandoned.*

1341. J. H. YOUNG. *Improvements in setting up, composing, and distributing types.* Dated June 14, 1858.

These improvements in setting up types relate chiefly to the composing machine patented by the inventor in 1840, in which an inclined plane is used for collecting the different types as they are required at one point; but they are also applicable to the machines in which moveable belts are used as a collecting medium. The inventor now claims:—1. The application of apparatus for obtaining a regulated alternate movement and stoppage to the step-wheel. 2. The application of apparatus for obtaining a regulated alternate movement and stoppage of the types upon the inclined plane, in order to insure their being properly taken off. 3. Making the steps of the step-wheel moveable. 4. The raising of the types at the termination of the inclined plane of the same, and the regulated action of the pusher so that it may not strike at an improper movement. 5. The application of electro-magnetism for regulating the taking off the types off the inclined plane, and their delivery into the receiver. 6. The application of a small auxiliary composing machine, which may be fixed to, or detached from, a larger or other composing machine. 7. The partial covering of the channels down which the types slide on the inclined plane. 8. The application of a groove for small bodied type in the bed of the channel of the inclined plane used for a larger bodied type. 9. The application of a pusher through the aperture or apertures so constructed in the incline plane to allow of superfluous types falling off the same. 10. The application of moveable blades to effect the distribution of types by means of their nicks as described. *Patent completed.*

1342. H. J. DANIELL. *A process by which the stamp on bankers' cheques is cancelled, and the cheque indelibly and simultaneously crossed.* Dated June 14, 1858.

This inventor claims the sole right to cross bankers' cheques, and cancel the stamp thereof by excision or perforation. *Patent completed.*

1343. H. N. S. SHRAPNEL. *An improvement in preparing iron and other metals or mixtures of metals for, and in casting the same in moulds.* Dated June 14, 1858.

Here the metals to be cast are, whilst in the furnace, subjected to a mechanical stirring; then run into the mould, and the stirring kept up until the metal solidifies. *Patent abandoned.*

1344. G. NEALL. *Improvements in gas stoves for warming, cooking, and other purposes; as also in the saucepans, kettles, or other utensils to be used with the same.* Dated June 14, 1858.

This specification is mainly a description of drawings. *Patent completed.*

1345. J. HETHERINGTON. *Improvements in guides or clearers used in machines for winding, reeling, and clearing threads of cotton, silk, and other fibrous materials.* Dated June 14, 1858.

This invention is for making guides or clearers from a solid piece of steel or other suitable material. The space for the thread to pass through is made wide at the top and tapering downwards, thus rendering it suitable to every count of thread between the coarsest and finest. An adjustable rod or bar is used for regulating the depth to which the thread is to be entered in the slit. These guides or clearers are fixed in the transverse rod or bar, or mounted on a spring in the same manner as ordinary guides. *Patent abandoned.*

1346. J. H. JOHNSON. *Improvements in machinery or apparatus for breaking or crushing stones for road metal, and other purposes; and for crushing ores and other hard and brittle substances.* Dated June 14, 1858.

This invention was described at p. 30, of No. 2, under the heading "Crushing Apparatus." *Patent completed.*

1347. J. C. HENDERSON. *Improvements in stoves.* Dated June 14, 1858.

This invention consists of a combustion chamber above the fire, and within a radiating chamber, whereby the smoke and gases are confined and submitted to perfect combustion. They then pass into the radiating chamber, from which the heat is communicated to the surrounding atmosphere, or to the substance to be heated. *Patent completed.*

1348. C. C. J. GUITTROY. *A new smoke-consuming apparatus, and also a new method of introducing the coal or fuel into it.* Dated June 15, 1858.

This invention was described at p. 620 of No. 1846 of the MECHANICS' MAGAZINE for Dec. 25, 1858. *Patent completed.*

1349. L. C. S. MASSON and F. DE LA MORINIERE. *Improvements in the manufacture of woven fabrics with coloured patterns.* Dated June 15, 1858.

The invention consists in so printing the threads which are to serve as weft for weaving fabrics as that by weaving by any of the ordinary methods tissues may be produced with a coloured pattern corresponding to any given design. *Patent completed.*

1350. B. PITT. *Improvements in the construction of knobs and roses used with locks, latches, and such like fastenings as are constructed with spindles.* Dated June 15, 1858.

Here the under rose consists of two parts—a metal plate screwed on the door, and having a neck with an external worm; and a collar fixed within the outer ornamental rose, and having in its interior a worm which screws on to the worm of the neck. The knob is jointed thereto by a nut, to allow it to revolve without affecting the ornamental rose, which is fixed by a small pin. Sometimes the under rose is attached to the lock instead of the door. *Patent completed.*

1351. G. ADSHEAD. *Improvements in steam boilers.* Dated June 15, 1858.

The inventor applies to boilers upon the tubular, flue, or other principle, a bridge or bridges constituting a water chamber or chambers; and in such arrangement he claims particularly the adaptation of springs at the lower and upper parts of the chambers communicating with the main part of the boiler. *Patent completed.*

1352. BARON F. J. VON WEDEL-JARLSBERG. *An improved self-registering compass, or control compass.* Dated June 15, 1858.

This specification is mainly a description of drawings. *Patent completed.*

1353. W. P. WILKINS. *Improvements in the arrangements and construction of refrigerating apparatus.* Dated June 15, 1858.

This invention refers principally to refrigerators used for cooling wort. The small tubes within the outer casing which contains the cooling liquor or water are held in the tube plates; but instead of fixing them rigidly thereto, the inventor simply slides them through holes formed to receive them. These tubes are arranged by preference in a circle within a cylindrical outer casing. In India-rubber discs of the diameter of the outer casing, he cuts holes corresponding with the positions of the several tubes, and places the discs on the ends of the tubes, which all project through the tube plates for the purpose. He then places washers or plates similarly formed with holes against the discs of India-rubber, and by screw studs and nuts compresses the India-rubber, thus rendering the joints tight, and at the same time admitting of expansion and contraction. The inventor also arranges channels or passages for the water in connection with suitable cocks, or valves, &c., whereby the water can be diverted from its ordinary course, and passed through the wort tubes in the opposite direction to that of the wort, whereby those tubes are readily cleaned out. The passage of the wort is then of course suspended. A third part of the invention refers to the introduction of a perforated metal disc in the outer chamber to sustain the tubes in the middle of their length (if long). This disc is similar to the washer used for compressing the India-rubber, but it has apertures for the passage of the water. *Patent completed.*

1354. SIR F. C. KNOWLES. *Improvements in the fabrication or manufacture of steel.* Dated June 15, 1858.

These improvements are as follows.—As soon as the metal is withdrawn from the converting furnace in whatever shape it may be (as bars, rods, sheets, plates, &c.), the inventor puts it into retorts without carbonaceous matter, and carefully excludes all atmospheric air. The retorts are then heated like gas retorts for a longer or shorter time, according to the size of the bars, &c., until the temper or cementation shall have become even throughout the mass and the steel itself almost homogeneous. The bars, &c., must then be drawn out and immediately covered up from the air with sittings of coke, and allowed to cool gradually in the heap. The inventor treats ingots of steel in the same manner to render them more homogeneous, and to destroy any crystallization, or state of strain in the mass among its molecules. If bars, rods, plates, &c., of steel after conversion (above all, if the iron from which they are made be itself clean and after this subsequent process in retorts be submitted to what is called "washing," heat, and then hammered, or rolled "shear" steel, or steel analogous to it, may be made without any welding process, highly homogeneous and solid, and less liable to crack under the hammer. *Patent completed.*

1355. H. S. WARNER. *Improvements in the manufacture of decolourizing and purifying charcoal.* Dated June 15, 1858.

This invention was described at p. 31 of No. 2 for Jan. 7, 1859.

1356. A. DEMBINSKY and A. C. ENGERT. *An improved fire-proof composition or wash.* Dated June 15, 1858.

This composition or wash is composed of sulphuret of potassium, silica, ground quartz or flint, soda or commerce, powdered charcoal, and pyroxalic acid. The whole of these ingredients are mixed and reduced to a flux under heat. The flux is afterwards diluted with boiling water down to the consistency required for use. Any equivalent ingredients may be substituted for any of the above-named. Many acids may be substituted for the acid mentioned, but pyroxalic acid produces the best effect. *Patent abandoned.*

1357. J. RUBERY and T. WARWICK. *Improvements in machinery and tools for making portions of umbrellas and parasols and lingoes.* Dated June 15, 1858.

In carrying out this invention steel wire is placed on a swift or reel at intervals, and a sufficient portion is drawn in to make a stretcher for an umbrella or parasol. The wire is then cut off to the length, and another pair of tools split the other end of the piece. The split wire is then by the machine carried laterally to two sets of tools which flatten the ends of it, and is then again carried laterally to two other sets of tools—one set to punch one end, and the other set to open and shape the split end. The stretcher thus formed is (still by the machine) moved laterally and delivered. The sets of tools mentioned are such as have been before employed. In making lingoes, the combination above described is somewhat varied, as the ends of these articles do not require splitting. In fixing the middle piece or joint of brass of the usual V shape to the steel ribs of umbrellas and parasols, the tools are so formed and worked as to fix the piece at one operation. The bed, die, or tool (whether made of one piece or more) has a slot through it, and a groove in the top, in which the rib is received and supported. Across the slot is a shaping tool, which corresponds in width with the brass piece which is to be fixed to a rib. On the edge of this tool is a recess corresponding with the form of the edge of the middle piece when finished. A split or double tool, the prongs of which are elastic, descends through the slot in the bed tool, and on either side of the brass or middle piece, by which the edges of the grooves formed in the edge of the brass or middle piece are gathered over the rib, and are then pressed on and finished simultaneously with the shaping of the other edge of the middle piece in the hollow tool across the slot in the bed tool, the parts of the spring tool being caused in its descent to come somewhat nearer together than the prongs are when they are free. *Patent completed.*

1358. B. PREDAVALLE. *Improvements in the mode of obtaining motive power.* Dated June 16, 1858.

This invention consists in working pistons, say on board ship, by means of "the decanter syphon," the short arm of which is immersed in the water, rising at the bow as the ship moves, and the long arm descending towards the water at the stern, the action of this syphon being "combined with the action alternately intercepted and restored of the vertical pressure of the water in the syphon upon the upper and lower parts of a piston or pistons" for giving motive power. A similar combination is used wherever water can be so employed as to act similarly—*i.e.*, in conjunction with a syphon. *Patent abandoned.*

1359. G. T. BOUSFIELD. *Improvements in apparatus to be used in the construction of small boats.* (A communication.) Dated June 16, 1858.

This invention consists of a certain apparatus for sustaining and confining the parts of the frames of small boats in the same relative positions as they occupy in the finished boat, and in certain accessories to such apparatus; the object of which is to cheapen the building by reducing the work in their construction. The patentee does not describe his invention apart from his drawings. *Patent completed.*

1360. B. ATWATER. *An improved sewing machine.* Dated June 16, 1858.

This invention was described at page 620 of the MECHANICS' MAGAZINE for Dec. 25, 1858, No. 1846; a complete specification having been filed with the application for a patent. *Patent completed.*

1361. C. W. LANCASTER. *An instrument or apparatus for charging cartridges for breech-loading arms.* Dated June 16, 1858.

This invention was described and illustrated at p. 361 of the MECHANICS' MAGAZINE for Oct. 16, 1858, No. 1838. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, FEBRUARY 18, 1859.

OUR STEAM NAVY.

A FLOOD of light is now pouring upon the navy of England. The discussion which was commenced in the middle of December last, stimulated by Her Majesty's announcement of an increase of expenditure "for the re-construction of the British navy," has brought down upon the public a deluge of information which it had but small reason to anticipate. In swift succession we have had the paper read at the Society of Arts on the ships of the navy, Sir HOWARD DOUGLAS'S *Naval Warfare with Steam*, and statistical leading articles and correspondence in the *Times*; and now, to-day, in our own supplement, we have those Admiralty tables which have been coveted, and sighed for, and begged, and stolen, and quarrelled over for months and even years past. And these are not all, for Sir CHARLES WOOD—touched with reasonable indignation at the ungenerous slight implied in the words of the Royal Speech, and determined to show that the navy was not neglected while under his care—has moved in Parliament for a return which will set forth in detail the vast work of "re-construction" which has already taken place.

A singular and fortunate conjuncture of things is observable in these facts. Sir CHARLES WOOD'S return was unquestionably moved for, less with the view of benefiting the public, than with that of justifying himself. Men of science might have asked him in vain, during his term of office, for the information which he has now elicited. But as soon as his personal reputation becomes shadowed, even by that very transparent cloud of words which Her Majesty was made to utter, forth come all the facts!

Singularly enough, we are in no position just now to urge this consideration against our Admiralties, because, before Sir CHARLES took action in the matter, the very valuable information which constitutes our Supplement was in our hands, and with it the Board of Admiralty's permission to publish it.

While giving that body of facts to the world, we would commend a word or two to the consideration of intelligent readers. The reluctance of official men to make bare the details of operations conducted in their departments will never be without excuse all the time those details are publicly discussed with injustice, animosity, or rancour. But few men are so heedless or so stoical as to bear unmerited aspersion and contumely if they can avoid them. And yet how often are persons in office subjected to both without cause! To fair discussion, however severe, we have not a word to oppose; but that ill-favoured spirit which is prone to attack, and cunning to impute bad faith everywhere, we abhor. For these reasons we hope that those of our readers who may hereafter examine and discuss the official papers of which we are to-day the channel, will do so with candour and right feeling. Let no gentleman mount a hobby-horse of any kind, and then attempt to traverse the expanse of facts and figures which we have spread out before him. On the other hand, all intelligent inquiry, all honest investigation, and all pure discussion we shall gladly hail.

THE NAVY ESTIMATES FOR 1859-60.

THE Navy estimates for the ensuing financial year 1859-60 were published this week. The grand total sum which the Legislature will be required to vote amounts to £9,813,181, being a net increase of £951,810 on the estimates of 1858-59, which amounted to £8,851,371. The principal increase occurs in the item No. 10, "naval stores, &c., for building and repairing ships," and in item No. 8, "wages to artificers employed at home;" these items together figure for an increase of nearly a million, or £985,707; the increase being asked "to meet the extraordinary charges to be incurred during the year in consequence of the additional work to be undertaken for the building and conversion of ships of war for the steam navy, and providing machinery for the same." Under item No. 10,—"Naval stores for the building, &c. of the fleet,"—£687,000 (the actual amount of the proposed increase) will be spent as follows,—viz., £82,000 for the purchase of timber, masts, and deals; £17,200 for other stores; £335,000 for the purchase of steam machinery and the repair of the same; and £252,000 for ships to be built by contract. Under item No. 8 the sum of £298,707 (the actual amount of the increase) is required to meet the extraordinary charges for dockyard labour. In the item for victualling, there is a decrease of £31,710; and in the item of "new works, improvements, and repairs in the yards," a decrease of £12,364.

The following is a list of the principal items of expenditure in the estimates for the ensuing year, viz:—Wages to seamen and Marines, £2,487,062; victuals for the same, £995,647; the Admiralty Office, £142,957; the Coastguard service and Royal Naval Coast Volunteers, £186,057; the scientific branch, £61.358; the establishments of Her Majesty at home, £153,089; and those abroad, £28,083; wages to artificers hired at home, £989,323 + £298,707 (the increase already explained); wages to artificers employed abroad, £54.330; naval stores, &c., for the building and repairs of ships, £1.484,240 + £687,000 (the increase already explained); new works, improvements, and repairs in the yards, £573,498; medicines and medical stores, £50,000; and miscellaneous services, £67,948. These items constitute the estimate of the effective branch of the service, and they amount altogether to £8,259,299. Under the head of the non-effective service, there are items of £706,509 for half-pay, reserved half-pay, and retirement to naval officers and Royal Marines; £483 957 for military pensions and allowances; and £163,416 for civil pensions and allowances. The item of the Army and Ordnance Departments (conveyance of troops) figures for £200,000. against £410,000 last year. The Royal Navy for the ensuing year is to consist of 38,000 officers, seamen, and boys to be employed in Her Majesty's fleet; 2,000 officers and men to be employed in the surveying, troop, and store ships; 4,000 officers and seamen to be employed in the Coastguard service afloat, and 3,400 officers and men to be employed in the same service on shore, the whole forming a grand total force of 47,400 officers, seamen, and boys; the navy proper includes 40,000, and the Coastguard, 7,400. There will also be a force of 15,000 Marines.

Literature.

Engineering Precedents for Steam Machinery; Embracing the Performances of Steamships, Experiments with Propelling Instruments, Condensers, Boilers, &c., accompanied by Analyses of the same; the whole being original matter, and arranged in the most useful manner for Engineers. By B. F. ISHERWOOD, Chief Engineer, U.S. Navy. New York: H. Baillière, 290 Broadway. London: H. Baillière, 219 Regent Street. 1859.

MR. ISHERWOOD'S name is known to us as that of the author of many useful papers published in the *Journal of the Franklin Institute*. In the volume before us he has brought together a mass of valuable facts, comprising a very full report on the British gun-boats, mainly the result of personal observation; a similar report on H. M. dispatch screw steamer *Lynx*; a third report on H.M. Steamship *Conflict*; a fourth on the steamers *Sydney, Ireland, and Scotland*; and a statement of the results of comparative experiments with the screw and paddle-wheel, as applied to the U. S. steamers *Spencer* and *McLane*. As the author intends, should the demand for this volume be deemed sufficient, to succeed it by others of like character, we would urge upon our readers the desirability of at once forwarding their orders for future volumes to the publishers. It would be a cause for great regret, if a series of practical engineering works like this should fail for want of due support.

The author professes to have derived most of his information respecting our gunboats from personal examination of those employed in the capture of Canton, which he saw during a cruise on the southern and eastern coasts of Asia. He says the gunboats sent to China proved of indispensable service in the military operations there, "and fully established the great value of this description of vessel for littoral warfare." By the courtesy of their engineers, he examined them both in dock and afloat, took the dimensions of their hulls and machinery, inspected their log-books, obtained indicator diagrams from their engines, and "received a candid account of their performance and general efficiency in the varying circumstances under which they had been tried." The author gives a minute detailed description of the hulls and engines of the several classes of gunboats, and enters into an elaborate comparison of the relative merits of the engines and propellers supplied respectively by Messrs. Maudslay and Field, and Messrs. Penn. As a specimen of the author's style the following passage on the 60-horse power gunboats (p. 9) may be taken:—

"This class was the original type of gun-boat, and the object had in view when constructing it, was to produce a vessel that could support two guns of large calibre for battering at point-blank range a formidable fortress, and at the same time offer a target of the smallest possible size to the enemy. For this purpose, the vessels were to be of very small dimensions with pretty full water lines, to be low on the water, and to have so light a draught as to be able to run close in shore; as they were to receive the fire of the heaviest hostile ordnance, their machinery was to be protected by being placed below the water line, and behind the shelter of the coal-bunkers. Their steam power was to be what was necessary to carry them rapidly in and out of action, and for prompt manœuvring against wind and current. As these vessels were constructed for the sole purpose of attacking Cronstadt, and were expected to be destroyed in that service (for both officers and crews were to be volunteers), excellence of model, kind of machinery, economical application of the power, capacity to perform sea voyages of reasonable length, etc., were quite secondary considerations—very different from what they would have been, had the vessels been destined for general instead of such special service. The great considerations were, small size hull, large size ordnance—the machinery being simply that which would weigh the least, cost the least, occupy the least space, and yet be sufficient for working the vessels quickly even against the current and wind, on the few occasions it was expected to use them. The accommodation for officers and crew, and the quantity of coal and stores carried, were, for the same reason, unimportant matters. The cannon, stores, coal, etc., were to be carried to the scene of action by large screw steamers, from which the gun-boats were to be fitted out, and sent in as bull-dogs to bait a bear. As a necessary consequence of this programme, the hulls were made with tolerably full water-lines, to give strength and displacement; the spars were made very small, and the machinery adopted was a light non-condensing engine, working at high rotatory speed, with a steam pressure of from 50 to 60 pounds per square inch above the atmosphere, and following for two-thirds the stroke of piston. The boilers were tubular, with circular shells—simplicity, fewness of parts, and readiness of access for quick and easy repair, being the governing objects. Only 28 tons of coal were carried in the bunkers, very little water was taken in the tanks, the distilling apparatus being depended on for the daily supply; provisions and stores were also restricted to the least quantity; and then the officers and crew, limited to the fewest number, were thrust into what little space remained.

The author is not correct in supposing that these vessels "were constructed for the sole purpose of attacking Cronstadt," and that they were expected to be destroyed in that service. His description of the vessels is, however, in the main truthful. In the following table (page 30) he gives a résumé of the dimensions of the hulls and screws of the different classes of gun-boats, and of the results obtained in respect of speed, power, distribution of the power, and economical appli-

Digitized by Google

cation of the same. This table may fitly appear in connection with the Official Admiralty Tables which are published in connection with this number of our Magazine:—

SCREWS.	DIMENSIONS.	Mean angle of the Helicoidal surface with the plane of the diameter, in function of surface and of its propelling efficiency	28°...52'	22°...50'	26°...52'	26°...16'
		Projected area in square feet, on a plane at right angles to axis	9·243	6·918	4·320	10·794
		Helicoidal area; in square feet	11·270	7·748	5·111	13·247
		Fraction used of the Pitch	4	4	4	4
		Pitch; in feet	8	6	6	8
		Diameter; in feet	6	6	4	6
		Slip of the Screws in per centum of their speeds	31·0	24·5	30·0	27·0
POWER.	DISTRIBUTION OF THE NET POWER APPLIED TO THE SCREW SHAFT; IN PER CENTUM.	In the Propulsion of the Vessel	60·18	65·43	43·67	62·81
		In the slip of the screw	27·03	21·23	43·67	23·23
		In overcoming the cohesive resistance of the water to the passage of the screw surface	5·29	5·84	5·16	6·46
		In overcoming the Friction of the Load	7·50	7·50	7·50	7·50
	RELATIVE ECONOMICAL EFFICIENCIES.	In respect of weight of steam consumed	1·04536	1·00000	0·63533	1·25661
		In respect of Net horses power applied to the screw shaft	0·91993	1·00000	0·66262	0·95987
		In respect of gross horses power developed by the engines	0·93315	1·00000	0·65611	0·97845
	ABSOLUTE QUANTITIES.	Pounds of Steam passed through the Cylinders per minute (representing Fuel)	194·83	127·74	85·00	169·42
		Net horses power applied to the screw shaft; per Indicator	207·82	171·04	108·58	316·35
		Gross horses power developed by the Engines; per Indicator	185·73	127·74	71·27	298·02
		Mean back pressure (including atmosphere) against Piston; in pounds per square inch	20·7	20·7	20·7	20·7
		Mean gross effective pressure on Piston; in pounds per square in.	40·00	32·96	27·40	42·80
DIMENSIONS OF THE HULLS.		Relative resistances of the Hulls	1·000	1·000	1·000	1·179
		Greatest immersed tranverse section; in square feet	130	130	95	142
		Mean draught of water; in feet	6·875	6·875	5·250	7·750
		Extreme breadth; in feet	22	22	22	22
		Length between perpendiculars; in feet	100	100	105½	125
Maximum speed per hour in smooth water uninfluenced by wind or current; in knots of 6,086 feet			8·38	8·26	6·20	9·27
CLASS.			60 Horses Power (Maudslay's Machinery)	Ditto (Penn's Machinery)	40 Horses Power	80 Horses Power

As the batteries of the gun-boats did not vary materially, the foregoing table shows the relative efficiency of the different classes carrying the same armaments at different speeds, with different draughts of water, and the relative cost of the same in power and fuel. The data here furnished must, however, be taken on Mr. Isherwood's authority, as we have not the means of verifying them. We hope he has been careful to examine sufficiently numerous examples of these vessels before venturing upon tabular inductions. He further tells us (p. 30) that

> The machinery of the gun-boats, though well made, and by the best builders, was constantly out of order. Both boilers and engines gave continual trouble; the first from the use of high pressure steam and sea water; the last from the high rotatory velocity employed. In fact, the rotary speed of the engines was so great that it was impossible to keep them in order. During the hostilities at and around Canton, the English established a shop on shore at Hongkong for repairing; they also had at the same place the floating workshop "Volcano," sent out from England completely fitted up with tools and power for doing a large amount of casting, forging, and finishing; and both these establishments were kept constantly employed on the gun-boats, there being, out of about fifteen, usually a couple undergoing repair; in fact the repairs upon them were enormous. For economy of fuel, durability, and reliability as war vessels for constant use, the machinery of these gun-boats cannot be recommended, however well adapted to the momentary purpose for which they were constructed

In his paper on the *Conflict* the author gives an elaborate account of experiments made with five different forms of propeller, viz., a common screw of uniform length from hub to periphery; a common screw with the corners of the blade rounded off; the same with a Griffith's globe at the centre; a common screw with its surface arranged to correspond with the Boomerang propeller; and lastly, the Boomerang propeller itself, by Sir Thomas Mitchell. In his discussion of the results of these trials he says (p. 93):—

> The relative economical efficiencies of screws experimented with in smooth water and uninfluenced by wind, are by no means the measure of their economical efficiencies at sea, struggling against the vicissitudes of weather, and an average increase of the normal resistance of the vessel from one-third to one-half, according to its size. This important consideration has too frequently, if not always, been overlooked in proportioning screws for marine propulsion; for which purpose the screw of least slip in smooth water is, in general, the most efficient. But with screws of equal diameter, a marked reduction of slip can only be obtained by lessening the pitch, which involves a greater speed of engine for equal speeds of vessel, and this is a very serious practical inconvenience, especially with large engines, as regards their durability and certainty of action. Some reduction of slip can, it is true, be obtained by employing a greater fraction of the pitch, but this involves, if carried beyond four-tenths, even in extreme cases, a disproportionately increased loss by the power required to overcome the cohesive resistance of the water; it also involves the no less serious practical inconvenience of increased length and weight of screw.

Again he says (p. 96) that from the experiments it appears how useless are any attempts to increase the efficiency of screws by modifying the outline of the blades.

> No taperings of the latter out or in, or inclinations of them from a perpendicular to the axis either in a longitudinal or lateral direction, and no removals radially of the surface by substitution of globes around the hub, or by other means, can add anything to the propulsive efficiency of the helicoidal surface, and they generally entail serious practical inconveniencies. The only improvement possible on the true screw of uniform length from hub to periphery, is that due to the use of an expanding pitch or curved directrix.

The remaining papers in the volume are exceedingly interesting, and merit the careful study of young engineers, the more so as they are written by a man accustomed to original and independent thinking.

A Manual of Applied Mechanics. By WM. JAS. MACQUORN RANKINE, LL.D, C.E., F.R.S.S., L. & E., President of the Institution of Engineers in Scotland, and Regius Professor of Civil Engineering and Mechanics to the University of Glasgow. London and Glasgow: Richard Griffin and Co, Publishers to the University of Glasgow. 1858.

NUMEROUS but hitherto unsatisfactory have been the attempts to produce what the civil and mechanical engineer is eminently in want of, viz., a manual of applied mechanics, embracing so much of mechanical philosophy as is required to give him a complete view of the subject, and at the same time exhibiting in a simple and attractive form the main applications of the philosophy to the structures and other combinations with which he is chiefly concerned. Perhaps no work so nearly satisfied these conditions in its own day as Emerson's. But mechanical philosophy, with its applications, has made immense strides since the time at which he flourished, and his labours are decidedly out of date. Since his time the treatises that have been published have been partial, written by persons incompletely acquainted with practical engineering, or so full of hobbies and crotchets as materially to detract from their value. France has indeed produced her Poncelet and Morin, who may be looked upon as the founders of the modern school of applied mechanics. Canon Moseley, who for some years filled the chair of Applied Science at King's College, London, followed in their wake, and produced a cumbrous work on the "Mechanical Principles of Engineering," of which we will only say that two-thirds are thrown away in the pursuit of an *ignis fatuus*—the development of the modulus of machines in a form intended to be practical, but in reality most unpractical and forbidding; while the nomenclature, arrangement, and general treatment of the subject are so intricate and involved as to render it the most difficult work to peruse we ever fell in with, and more calculated to repel than to attract the attention of the engineering class for whom it was professedly intended. It cannot, then, be denied that there was ample room for the appearance of such a work as that of Professor Rankine, whose education as a civil engineer, and undoubted mathematical attainments, would point to him as an eminently fitting person to undertake the task—the round man in the round place. It was therefore with no small anticipations of profit that we addressed ourselves to the task of mastering the bulky volume of 640 pages which Professor Rankine has produced.

In order to enable our readers to understand how far our expectations have been realized, we will first premise how we should expect such a subject to be treated. Now, there are undoubtedly two aspects under which mechanical philosophy might present itself to the mind of such a man as Professor Rankine. He might view it as a system of pure scientific truth, to be exhibited in a complete and logically coherent form, without any special reference to its practical applications, but with all the beautiful refinements so delightful to the accomplished mathematician, but possessing but little interest for the engineer. Under such an aspect he would regard the requirements of the professed mathematician—the lover of the science for its own sake—rather than him whose daily occupation is the practical application of scientific principles. In that case, assuming a very considerable acquaintance with the more abstruse and powerful instruments which modern analysis places at our disposal, regarding more the unity of his structure than the simplicity of the several stages employed in its erection, he would elaborate a work most useful in a purely scientific point of view, and most valuable to the theorist—a work calculated to raise his name to a high eminence in the philosophical world, but of little practical value. Such a work would not be fitly called "A Manual of Applied Mechanics," but a "Treatise on Mechanical Philosophy." Or, he might take a practical view of this subject, and, desirous of putting into the hands of the engineer an adequate rationale of the operations he daily puts into practice in his professional calling, and an exposition of the scientific principles which would materially aid him in calling into being any fresh combination of architectural or engineering forms, he would proceed on exactly the opposite track; he would care less for the aplomb—the completeness of his speculations—that, in fact, which would be its most pleasing feature to the accomplished mathematician, than for its adaptability to the wants of those whose scientific attainments are not so extensive, for whom an easy and intelligible explanation is the great desideratum. Such a work, troubling itself little about excursions into mere scientific enquiry, which have no practical outlooks, but keeping in view solely the daily requirements of the practical man, would avoid as much as possible the use of recondite abstruse mathematical methods, would never travel except by absolute compulsion beyond the most ordinary

Digitized by Google

paths of algebraical and geometrical investigation, and would confine its necessary incursions into the regions of the differential and integral calculus to their most simple and intelligible parts. We should expect in such a work a clear definition of terms, a simple exposition of methods and principles, travelling upwards by degrees from the more elementary to the more difficult; and we should expect at every turn the practical bearing of these principles to be fully pointed out, and amply illustrated where possible by numerous examples. Such a work, to which the engineer could readily refer for guidance, would be deservedly called "A Manual of Applied Mechanics."

But in both the one and the other of such treatises as we have indicated we should have a right to expect from a competent author an abstention from unusual and incorrect use of terms, and from slovenly, illogical methods. An unfortunate and most mischievous notion has apparently taken possession of practical writers on mechanics of late years—that in order to be practical it is necessary to be loose and indefinite; and if a book were to commence with a strict logical definition of terms, these gentlemen would instantly delegate it to the regions of the unreal and unpractical. Such books as Tate, Hann, and others of that school have put forth, professing to be eminently calculated to inform the practical mind, have done more mischief to the cause of the reconciliation of theory and practice, to say nothing of mechanical truth, than will easily be effaced. To grasp correctly, for instance, the true idea of force, and to separate it from other effects which are too often confounded with it in the popular mind, and thus to see the way clearly through Newton's brilliant explanation of the motion of the heavenly bodies—the principles of which are no less applicable to mundane machines—is doubtless no easy matter, and one in which many make a desperate failure. But it by no means improves the matter to be content with incorrect and insufficient notions of force; for these only lead to confusion worse confounded. How much miserable twaddle has been written on conservation of force, the moon's motion, &c., &c., founded on the purest misconceptions of the most elementary principles to which these so-called *practical* treatises give direct encouragement, if not by positive misstatement, at all events by the negative process of lax and insufficient statement. It is either the most vulgar prejudice and ignorance, or the most arrant imposition, to uphold, whether theoretically or practically, the false assumption that there is less need of logical accuracy in the terms and processes of practical than in those of theoretical mechanics. Force, for example, cannot be one thing when employed in the explanation of the motion of the heavenly bodies, and another thing—more indefinite and loose—when applied to structures or machines. If it require the exercise of some of the highest powers of the mind to grapple with it in the one case, it cannot need merely the indolent exercise of superficial thought in the other. And yet, to judge from the style of so-called practical works—aye, and of considerable repute, too—the main difference between the practical and theoretical, in matters of science, might be better expressed by the terms, *loose and illogical, strict and logical.* So much by the way. We are glad to have an opportunity of entering our protest against one of the most mischievous fallacies which have ever prevented the happy union of theory and practice.

Having premised our opinion as to the two several aspects under which an author might view the subject of applied mechanics, strictly theoretical or strictly practical, it is now time to enquire how far Professor Rankine has satisfied the conditions we have assigned to either of these two views. And we must honestly record our opinion that the work before us, viewed in either light, is to a considerable extent a failure. The author seems to have been embarrassed between the two conceptions we have pointed out. On the one hand, he could not tear himself from the desire to exhibit his subject in a complete and exhausting form, and thus to deviate from the true path of the practical writer; and, on the other hand, in his desire to be practical he has seriously marred its proportions and unity as a purely philosophical work. We do not deny the existence of great merit in the mode of treating many of the subjects; but in its present form the book is a veritable hotch-potch, repugnant to the good taste of the theorist—repulsive to the judgment and beyond the powers of the engineering student. The bulkiness of its form, the introduction of much matter having no practical bearing at all, the meagreness of illustrative examples, the high pretensions of much of the theoretical investigations, elevated into the regions of the abstruse far beyond the ken of the tyro, and in many cases the unnecessary involvement of the nomenclature and symbols, place it out of the reach of the latter; while the former, though gratified by a study of many of the details, is shocked by a laxity of definition and investigation in many cases, and more especially by a most signal failure in the exposition of the first principles of the science, which goes far to undo the favourable impression of Professor Rankine's powers which many separate portions of the work are well calculated to beget. We believe that we have offered the true explanation of this failure—for so we fear we must characterise it—of a man of such undoubted powers as Professor Rankine professedly is, by the theory that like the well-known donkey, he found himself between two bundles of hay—pure theory and true practice—and could not make up his mind to which to incline, and by making a point now at one and now at the other, has ended, like the wise quadruped in question, by missing both.

We think, too, that we detect another cause of failure, viz., that our author is too willing to exhibit originality; and in attempting to avoid the beaten track, has stumbled on byeways, original enough no doubt, but leading far away from the goal he has in view. In the work before us, there is ample stuff for the making of a good theoretical and a good practical work on "Applied Mechanics;" but we confess that from the specimen we have here of the bias of our author's mind, we are much more inclined to predict success for him in the former than in the latter attempt. Nor in saying this are we aware that we say anything disparaging to Professor Rankine as a man of science and of original thought. It too frequently happens that such persons are incapable of descending to the level of more ordinary thinkers—that the drudgery of wading through the elementary principles of a science without making a flight into the more abstruse is too insufferable, and rather than to submit to tell the thrice-told tale, such minds will rather run into brilliant but original error. Professor Rankine is evidently much more at home in the application of the highest instruments of analysis to the investigation of recondite questions than he is in the more humble task of making first principles plain to the anxious student. We suspect that he will find a more useful field for his labours in the pursuit of those investigations which have gained him a name in the scientific world, than in an attempt to write a more "practical" and useful "*Manual* of Applied Mechanics." We must now, for the present, take leave of this work, but we shall soon recur to the subject, and justify by an analysis of the treatise before us the broad opinions we have now expressed.

Illustrations of Carpentry and Framing. By ROBERT SCOTT BURN. William and Robert Chambers: London and Edinburgh, 1859.

THIS is one of a series of works which Messrs. Chambers are bringing out as "Practical Diagrams and Working Drawings for Schools." It contains drawings (to scale) of roofs, partitions, floors, joints of timber and iron framing, trussed beams, cast-iron columns and beams, and wrought-iron roofs, with details of the various parts; together with several pages of notes on the principles of framing and the form of beams, by Mr. R. Scott Burn, whose ability as a writer on mechanical subjects is well-known. The design and plan of the book are well conceived, and in its preparation Messrs Chambers have again attained their long-accustomed excellence. It is well calculated to impart elementary instruction upon a subject which requires to be brought forward prominently as a branch of school education.

Parliamentary Proceedings.

[CONDENSED FOR THE "MECHANICS' MAGAZINE."]

HOUSE OF COMMONS.

THURSDAY, Feb. 10.

NEW FOREIGN OFFICE.

Mr. TITE gave notice that, on the motion for adjournment to-morrow, he should ask what steps had been taken for rebuilding the Foreign Office in Downing-street.

NAVAL ESTIMATES.

Lord J. RUSSELL asked the First Lord of the Admiralty on which day he would bring forward the Naval Estimates, and make the statement of which he had given notice?

Sir J. PAKINGTON—I propose to make a statement of the views of the Government on the Naval Estimates on Friday, the 25th instant.

MARINE ENGINES.

Mr. DALGLISH asked the First Lord of the Admiralty any tenders had been recently given out for marine engines; and, if so, whether the marine engineers of the river Clyde had been asked to tender?

Sir J. PAKINGTON said that tenders for marine engines had been lately called for to a large amount; that a larger number of manufacturers than usual had been invited to tender; and that among them was one manufacturing firm upon the Clyde—the Napiers.

NAVY ESTIMATES.

Mr. CORRY brought up the Navy Estimates, which were ordered to be laid on the table.

FRIDAY. Feb. 11.

PATENT LAW.

Mr. T. DUNCOMBE wished to know whether it was the intention of the Government to introduce any measure for the improvement of the working of the Patent Law Amendment Act (1852), or to reduce the stamp duties payable on letters patent for inventions, especially the 50*l.* payable before the expiration of the third year, and the 100*l.* payable before the expiration of the seventh year, of the patent right, which falls due next autumn.

Sir S. NORTHCOTE said it was not the intention of the Government to make any alteration in the Patent Law further than this, that the alteration in the site of the Patent-office would greatly facilitate the business. It was not at present the intention of the Government to reduce the stamp duties now payable upon patents. The present duties of 50*l.* and 100*l.* were part of a system intended to facilitate the taking out of patents, the patentee only having to pay the larger sum after a certain term of years, when the patent was likely to be remunerative. The period when the payment of 100*l.* would have to be made was now approaching, and it was not the intention of the Government to make any alteration in this respect.

THE NAVY.

Sir C. WOOD moved for the following returns:—Of the number of steamships and vessels added to the navy in the year 1848, and each subsequent year, divided into ships of the line, frigates, and other classes of vessels, and distinguishing those which have been built, converted, and purchased, with the total of each class in each year, and grand total in all the years; and of the number of steamships and vessels in the navy afloat, and building or converting, on the 1st day of January, 1859, divided into ships of the line, frigates, and other classes of vessels, and distinguishing screw and paddlewheel vessels.—Agreed to.

THE BRITISH MUSEUM.

Lord ELCHO asked the Chancellor of the Exchequer, whether Her Majesty's Government had come to any determination as to the enlargement of the British Museum, or the arrangement and distribution of its heterogeneous collections?

The CHANCELLOR of the EXCHEQUER said the arrangement of the British Museum was still under the consideration of the Government.

RAILWAY ACCIDENTS.

Mr. BENTINCK asked the President of the Board of Trade whether it was the intention of Her Majesty's Government to introduce any measure during the present session founded on the report of the Select Committee on Railway Accidents?

Mr. HENLEY said there was no doubt a great deal in that report well worthy of consideration, but the Government had not thought it desirable to institute any measure solely on that report. If any legislation concerning railways should take place it would then be their duty to consider whether those valuable suggestions could not be embodied in the measure.

NEW FOREIGN OFFICE.

Mr. TITE, in asking what steps had been taken relative to rebuilding the Foreign Office in Downing-street, complained of the passing by of Mr. Barry, the first prizeman in the late competition, and the selection of Mr. Scott, the second prizeman, and stated that a building of Mr. Scott's design would be both inconvenient and expensive.

Lord J. MANNERS made an elaborate reply, and stated that the design of Mr. Scott was being somewhat amended,

Digitized by Google

and when finally finished would be placed in the library of the House for the inspection of members.

Further remarks were made by Mr. HOPE, Mr. CONINGHAM, General THOMPSON, Lord PALMERSTON, and Mr. BENTINCK.

MONDAY, Feb. 14.

INDIAN PUBLIC WORKS.

Lord STANLEY, in laying his statement on Indian finance before the House, gave an elaborate account of the railways of India; and, with regard to other public works, not railways, mentioned the most important lately sanctioned:—First, the Madras Irrigation Company has received a guarantee of 5 per cent. upon £1,000,000; second, at Madras a pier has been ordered at a cost of £103,000, which is to be completed in two and a-half years; third, at Kurrachee works costing £140,000 are sanctioned for improving harbours, the period for completing which is spread over three or more years; fourth, plans have been directed to be prepared for improving the harbour of Sedashevaghur, south of Goa, and connecting it with the country inland; fifth, a plan for rendering the Godavery navigable for a distance of 300 miles is referred to Madras; and, sixth, there has been a considerable outlay upon small steam cargo-barges and tugs for the navigation of the Ganges and the Indus—15 vessels in all. He did not mention smaller undertakings, which, though of local importance, are of no general interest; but two plans have been taken in hand by the Government which are of an important character. One is the establishment of telegraphic communication between this country and India. After the failure of the experiment with the Atlantic cable it was impossible not to feel that the undertaking presented a greater amount of difficulty and a greater risk of failure than had been at first anticipated. But, whatever the difficulty or risk the object appeared to the Government to be one of so much importance, and the saving that would be effected in every way so great, that they thought it to be their duty to incur that expenditure. A guarantee of 4½ per cent. upon a capital of £800,000 was accordingly given, and operations were begun at once. The cable is nearly ready, and the promoters anticipate that they will be able to lay it as far as Aden by June next. Beyond Aden, where the line touches the southern coast of Arabia, which is inhabited by wild tribes, there is more risk, and the difficulties are considered greater. The Bombay Government will, however, offer all the assistance in their power. But we do not rely upon a single line. The Turkish Government have initiated a line of their own from Constantinople to Bussaret, and the Indian Government on its own account, or some private company, will undertake the completion of that line on to Kurrachee. In this way the risk of interruption will be less. The other scheme which has received the sanction of the Government relates to the supply of civil engineers for the East India service. It is proposed to appoint a special engineering service. The appointments will be competed for by young men of a certain age. They will be required to have passed through a certain practical training here, and they will be sent to India on a small salary to acquire further instruction in their duties. They will then be regularly taken into Government employ for life, with pensions at the same rate, probably, as are given to other uncovenanted servants.

PIERS AND HARBOURS.

Mr. PAULL moved for leave to bring in a Bill to encourage and facilitate the erection of piers and harbours in Great Britain and Ireland.

Lord LOVAINE said that a Bill had been prepared by the Admiralty, which would, he believed, attain all the objects which the hon. gentleman had in view.

Leave was then given to introduce the Bill.

TUESDAY, Feb. 15.

MERSEY DOCKS AND HARBOUR BILL.

Mr. HORSFALL moved the second reading of this Bill.

Mr. TOLLEMACHE moved that it be read a second time this day week, on the ground that it was intended to give the Mersey Dock Board power to raise £300,000 on the trade of the country, when no definite plan had yet been settled.

Mr. SALISBURY supported the motion for postponement, and charged the Dock Board with a breach of faith.

Mr. J. EWART denied that any breach of faith had been committed.

Mr. CHEETHAM supported the second reading.

Mr. HORSFALL denied that there had been any breach of faith. On the contrary, they had done more for Birkenhead than they were under obligation to do. The steam trade of Liverpool had doubled, the timber trade had trebled, and it was to those trades that the Bill had special reference.

Mr. LOWE opposed the Bill.

Mr. HENLEY denied that it had ever been stipulated that no public improvement should be undertaken at Liverpool until the Birkenhead works were, not simply in progress, but actually completed.

Sir B. HALL, as Chairman of the select committee, stated that last year the dock trustees desired to raise 800,000*l.*, to be expended upon the Liverpool side of the Mersey. At that time there was a most distinct understanding come to that that sum should be reduced to 266,000*l.*, and even before that amount was granted the dock trustees pledged themselves that no more money should be expended upon the Liverpool side of the river until the Birkenhead Docks should be advanced almost to completion.

Mr. TURNER supported the second reading.

The House divided, when the numbers were—

For the second reading	181
Against	102
Majority	79

The Bill was then read a second time.

THE THEORY OF NAVAL ARCHITECTURE.

No. IV.

ANOTHER method of approximating to a curvilinear area, is to draw a cubic parabola through the extremities of four consecutive equidistant ordinates, to calculate the area of the figure between this curve and its other boundaries, and take it to be equal to the area required, neglecting as inappreciable the very small area between the parabolic curve and the given curve.

The general equation to what is called the cubic parabola (on account of the third power of x entering into it) is $y = A + Bx + Cx^2 + Dx^3$.

Take as before in Fig 8, $P_1 N_1$, $N_1 N_4$, as the co-ordinate axes of y and x respectively; a_1, a_2, a_3, and a_4 the ordinates, corresponding to x equal to 0, m, $2m$, and $3m$ respectively. Then we have four equations,

$$a_1 = A \quad (1),$$
$$a_2 = A + Bm + Cm^2 + Dm^3 \quad (2),$$
$$a_3 = A + 2Bm + 4Cm^2 + 8Dm^3 \quad (3),$$
$$a_4 = A + 3Bm + 9Cm^2 + 27Dm^3 \quad (4).$$

From which equations the values of A, B, C, and D are readily obtained. Substitute in (2), (3), and (4) a_1 for A, multiply (2) by 2 and also by 3, and subtract the results from (3) and (4) respectively, whence

$$a_3 - 2a_2 + a_1 = 2Cm^2 + 6Dm^3 \quad (5),$$
$$a_4 - 3a_2 + 2a_1 = 6Cm^2 + 24Dm^3 \quad (6).$$

Multiplying (5) by 3 and subtracting from (6)

$$a_4 - 3a_3 + 3a_2 - a_1 = 6Dm^3,$$

also from (5)

$$2Cm^2 = a_3 - 2a_2 + a_1 - 6Dm^3$$
$$= -a_4 + 4a_3 - 5a_2 + 2a_1.$$

Substituting the value of Cm^2 and Dm^3 thus found in (2), and transposing $6Bm = 2a_4 - 9a_3 + 18a_2 - 11a_1$, and the equation to the cubic parabola through the extremities of four consecutive ordinates is

$$y = a_1 + \frac{2a_4 - 9a_3 + 18a_2 - 11a_1}{6m} \cdot x + \frac{4a_3 - a_4 - 5a_2 + 2a_1}{2m^2} \cdot x^2 + \frac{a_1 - 3a_3 + 3a_2 - a_1}{6m^3} x^3 \quad (A).$$

To obtain the area of the figure $P_1 P_4 N_4 N_1$ when the curve is that of the cubic parabola.

Divide $N_1 N_4$ into a large number ($3n$) of equal parts, n of them being contained in the common interval m between the ordinates; imagine ordinates y_0, y_1, y_2, &c., y_{3n} drawn through the points of division; y_0 corresponding to a_1, and y_{3n} to a_4, and join the points where consecutive ordinates cut the curve by straight lines, thereby forming $3n$ small trapeziums. From the general equation to the cubic parabola we have

$$y_0 = a_1;$$
$$y_1 = a_1 + B \cdot \frac{m}{n} + C \cdot \frac{m^2}{n^2} + D \cdot \frac{m^3}{n^3};$$
$$y_2 = a_1 + B \cdot \frac{2m}{n} + C \cdot \frac{2^2 m^2}{n^2} + D \cdot \frac{2^3 m^3}{n^3};$$
$$y_3 = a_1 + B \cdot \frac{3m}{n} + C \cdot \frac{3^2 m^2}{n^2} + D \cdot \frac{3^3 m^3}{n^3};$$
$$\&c. = \&c.$$
$$y_{3n-1} = a_1 + B \cdot \frac{\overline{3n-1} \cdot m}{n} + C \cdot \frac{\overline{3n-1}^2 \cdot m^2}{n^2} + D \cdot \frac{\overline{3n-1}^3 m^3}{n^3};$$
$$y_{3n} = a_1 + B \cdot \frac{3nm}{n} + C \cdot \frac{3^2 n^2 m^2}{n^2} + D \cdot \frac{3^3 n^3 m^3}{n^3}.$$

The area of the first trapezium $= \frac{y_0 + y_1}{2} \times \frac{m}{n} = a_1 \cdot \frac{m}{n} + \frac{B}{2} \cdot \frac{m^2}{n^2} + \frac{C}{2} \cdot \frac{m^3}{n^3} + \frac{D}{2} \cdot \frac{m^4}{n^4}$;

„ second „ $= \frac{y_1 + y_2}{2} \times \frac{m}{n} = a_1 \cdot \frac{m}{n} + \frac{B}{2} \cdot \frac{3m^2}{n^2} + \frac{Cm^3}{2n^3}(1^2 + 2^2) + \frac{Dm^4}{2n^4}(1^3 + 2^3)$;

„ third „ $= \frac{y_2 + y_3}{2} \times \frac{m}{n} = a_1 \cdot \frac{m}{n} + \frac{B}{2} \cdot \frac{5m^2}{n^2} + \frac{Cm^3}{2n^3}(2^2 + 3^2) + \frac{Dm^4}{2n^4}(2^3 + 3^3)$;

&c. $= \&c.$ $= \&c.$

„ last „ $= \frac{y_{3n-1} + y_{3n}}{2} \times \frac{m}{n} = a_1 \cdot \frac{m}{n} + \frac{B}{2} \cdot \overline{6n-1} \cdot \frac{m}{n} + \frac{Cm^2}{2n^2}(\overline{3n-1}^2 + \overline{3n}^2) + \frac{Dm^3}{2n^3}\left\{\overline{3n-1}^3 + \overline{3n}^3\right\}$.

Sum of all the trapeziums $= a_1 \left\{\frac{m}{n} + \frac{m}{n} + \frac{m}{n} + \&c. \text{ to } 3n \text{ terms}\right\}$ or $3a_1 m$

$$+ \frac{Bm^2}{2n^2}\left\{1 + 3 + 5 + \&c. \text{ to } 3n \text{ terms}\right\} \text{ or } \frac{Bm^2}{2n^2}(3n^2)$$
$$+ \frac{Cm^3}{n^3}\left\{1^2 + 2^2 + 3^2 + \&c. \text{ to } \overline{3n-1}^2 + \frac{3^2 n^2}{2}\right\} \text{ or } \frac{Cm^3}{n^3}\left(\frac{3n}{6} + \frac{3^3 n^3}{3}\right)$$
$$+ \frac{Cm^3}{n^3}\left\{1^3 + 2^3 + 3^3 + \&c. \text{ to } \overline{3n-1}^3 + \frac{3^3 n^3}{2}\right\} \text{ or } \frac{Dm^4}{n^4}\left(\frac{3^2 n^2}{4} + \frac{3^4 n^4}{4}\right)$$
$$= 3a_1 m + \frac{B9m^2}{2} + 9Cm^3\left(1 + \frac{1}{18n^2}\right) + \frac{81Dm^4}{4}\left(1 + \frac{1}{9n^2}\right)^*$$

This expression represents the sum whatever n may be. When n is infinitely large, the sum of these trapeziums will be the exact area included between the parabolic curve and the other boundaries of $P_1 N_4$; and the qualities $\frac{1}{18n^2}$ and $\frac{1}{9n^2}$ vanish.

---

* The sum of the series $1^3 + 2^3 + 3^3 + \&c. + (3n)^3$, may be found by the method of Indeterminate Coefficients, thus—

Assume $1^3 + 2^3 + 3^3 + \&c. + (3n)^3 = {}^3A + B \cdot 3n + C(3n)^2 + D(3n)^3 + E(3n)^4 + \&c.$,

writing $3n + 1$ for $3n$;

$1^3 + 2^3 + 3^3 + \&c. + (3n)^3 + (3n+1)^3 = A + B(3n+1) + C(3n+1)^2 + D(3n+1)^3 + E(3n+1)^4 + \&c.$

Subtracting the first equation from the second

$$(3n+1)^3 = B + C(6n+1) + D(27n^2 + 9n + 1) + E(108n^3 + 54n^2 + 12n + 1);$$

Digitized by Google

$$\therefore \text{Area} = 3a_1m + \frac{B}{2}.9m^3 + 9Cm^3 + \frac{81Dm^4}{4}.$$

Putting for B, C, and D their values already found, given in the general equation (A); multiplying out and arranging we have, area $= \frac{3}{8}m\,(a_1+3a_2+3a_3+a_4)$.

The area between the ordinates a_4 and a_7 will be, writing a_4, a_5, a_6 and a_7 for a_1, a_2, a_3, and a_4 respectively, $\frac{3}{8}m\,(a_4+3a_5+3a_6+a_7)$.

Between the ordinates a_7 and a_{10} the area will be $\frac{3}{8}m\,(a_7+3a_8+3a_9+a_{10})$,

and so on continually. Consequently the whole area between the first ordinate a_1 and $\overline{3p+1}^{th}$ ordinate, represented by a_{3p+1} (where p is any natural number), is

$$\frac{3}{8}m\left\{a_1+a_{3p+1}+3\,(a_2+a_3+a_5+a_8+\&c.)+2\,(a_4+a_7+a_{10}+\&c.+a_{3p})\right\}.$$

Whence the following rule, to find any curvilinear area like that represented in Fig. 8 when the number of equidistant ordinates is some multiple of three increased by one, or when the number of equal spaces is a multiple of three:—

RULE. 1° *Add together the first and last ordinates.*

2° *Add together the second, third, fifth, and all the other ordinates except those which are multiples of three increased by one: and multiply by three.*

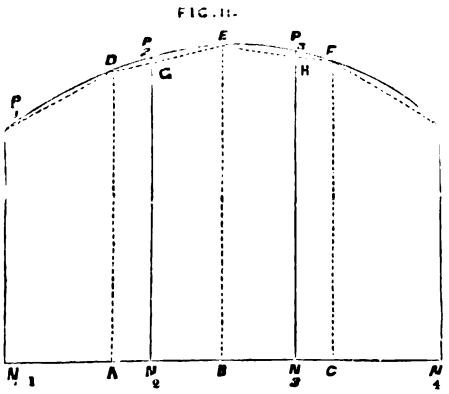
3° *Add together all those ordinates which are multiples of three increased by one, multiply the sum by 2.*

The sum of the three results here found, multiplied by $\frac{3}{8}$ths the common interval, will give the whole area required.

This is called Rule 3.

By an artifice similar to that employed by M. Poncelet for proving the rule to find the curvilinear area when there are three equidistant ordinates, we may prove the above rule for finding the area when there are four equidistant ordinates. Let $P_1P_4N_4N_1$ (Fig. 11) be the curvilinear area required, the ordinates of which are represented by a_1, a_2, a_3, and a_4, and the common interval between them by m. Divide N_1N_4 into *four* equal portions in the points A, B, and C, and through these points draw AD, BE, and CF, perpendicular to N_1N_4 meeting the curve in the points D, E, and F, respectively: join P_1D, DE, EF, and FP_4 by straight lines, thus forming four trapeziums.

FIG. 11.



Let the straight lines DE and EF cut P_2N_2 and P_3N_3 in G and H respectively.

Now $N_1A = AB = BC = CN_4 = \frac{3}{4}m$.

$$\text{And the Area of trapezium } P_1A = \frac{3m}{4}\left(\frac{P_1N_1+AD}{2}\right) = \frac{3}{8}m(a_1+AD);$$

$$\text{,, ,, } DB = \frac{3m}{4}\left(\frac{AD+BE}{2}\right) = \frac{3m}{8}(AD+BE);$$

$$\text{,, ,, } EC = \frac{3m}{4}\left(\frac{BE+CF}{2}\right) = \frac{3m}{8}(BE+CF);$$

$$\text{,, ,, } FN_4 = \frac{3m}{4}\left(\frac{CF+P_4N_4}{2}\right) = \frac{3m}{8}(CF+a_4);$$

$$\text{Sum of all the trapeziums} = \frac{3m}{8}\left\{a_1+a_4+2AD+2CF+2BE\right\}.$$

In the Figure $N_2G = AD + \frac{1}{3}(BE - AD) = \frac{2AD+BE}{3}$;

$\therefore 2AD + BE = 3N_2G = 3P_2N_2$ nearly, since G is very near to P_2, the ordinates not being far apart.

In the same manner it may be proved that $2CF + BE = 3P_3N_3$ nearly;

$\therefore$ sum of all the trapeziums $= \frac{3m}{8}(a_1+a_4+3a_2+3a_3)$; and since putting P_2N_2 and P_3N_3 instead of N_2G and N_3H will give a small increase to the area above that of the trapeziums, and the curvilinear area is also a small increase over that of the same trapeziums, it is readily seen that, approximately, the curvilinear area $= \frac{3m}{8}(a_1+a_4+3a_2+3a_3)$.

Proceeding as above with the other sets of four equidistant ordinates, the Rule 3, just stated, is readily obtained.

---

all the other terms after E being separately equal to Zero, since there is no term on the left hand side of the equation in n^4.

$$\therefore 27n^3+27n^2+9n+1 = 108En^3+(54E+27D)n^2+(12E+9D+6C)n+B+C+D+E.$$

Equating like powers of n we have

$$\begin{aligned} 108E &= 27 && \text{or } E = \tfrac{1}{4}\\ 27D+54E &= 27 && \text{or } D = \tfrac{1}{2}\\ 6C+9D+12E &= 9 && \text{or } C = \tfrac{1}{4}\\ B+C+D+E &= 1 && \text{or } B = 0\\ & && \text{also } A = 0 \end{aligned}$$

$$\therefore 1^3+2^3+3^3+\&c.\ldots\ldots+3^3n^3 = \frac{3^2n^2}{4}+\frac{3^3n^3}{4}+\frac{3^4n^4}{4};$$

$$\text{and } 1^3+2^3+3^3+\&c.\ldots\ldots+\overline{3n-1}^3+\frac{3^3n^3}{2} = \frac{3^2n^2}{4}+\frac{3^4n^4}{4}$$

$$= \frac{3^4n^4}{4}\left\{1+\frac{1}{9n^2}\right\} = \frac{81n^4}{4}\left(1+\frac{1}{9n^2}\right).$$

ON A QUICK-WORKING POWER ENGINE.

(Continued from p. 91)

THE PLAN.

SUPPOSE a double pump, with cylinders of large diameter, short, and set far enough apart for the strokes of the pistons to be sufficiently long. Suppose at its front, two pipes of large bore rising from near the bottoms of the cylinders at the nearest opposite sides, and united before they reach the top of the pump, so as to form one pipe. This should pass over between the cylinders and descend perpendicularly at the back, tapering to an end on a very shallow close reservoir. Suppose that, besides the valves in the bottoms, there is a vertical one at the side of each cylinder, hinged at the lower edge of the opening into the pipe. Lastly, suppose the single pipe formed by the junction of the other two to be divided just under its bend, by a space which an oblique sliding-valve should fill, and this part to be inclosed, to form a small chamber where a vacuum might be made.

There should also be a valve to be slid up and down at the junction of the pipes; because, otherwise, when the working was stopped by thrusting in the other valve, the water which could circulate through the junction of the pipes would not instantly hold the pistons fast, as would be necessary with a view to starting again—a point that will be further explained.

The above are the main features of the plan: the following are minor details, but in part not less essential to the success. The valves in the bottoms should be coupled under the pump by a bar moveable up and down on a support at the middle and bent upwards at the ends, where it should be attached to the under surface of the valve, so that, when horizontal, it should hold them a little open, in order that when one was raised to double the extent, it might, through the bar, hold the other down tight. The reason is, that the pressure from the reservoir tending to open the valve that should be closed would be very far stronger than the downward pressure from the piston over it, tending to keep it closed. The coupling bar, its fastenings, and the valves must be strong. The influx, the force of which would be relied upon, might be strengthened by the bottoms of the cylinders being shaped like hollow cones, with openings at the truncated summits, to which a body of water would run up as through a short tapering pipe.

The strokes being intended to be much longer than in common pumping, the parrellel motion should be applied to the pistons. Then opposite to where the rods in that mechanism would issue from the tubes that contain them, four worm springs should be placed so that, with the pistons fixed at the highest and lowest levels by the ends of the beam preparatively to the pivot stroke, one spring above and one below might be pressed by screws in framework into tension against the upper end of one and the lower of the other. The other two would be screwed forwards not so much (and the first two should be screwed a little back after they had served the purpose of starting), to be forced into tension at the end of the stroke. The reaction of the two couples in their turns would cause the changes of the strokes to be without any interval of time.

There should be a stopper on an opening of the reservoir, to be loaded or unloaded for safety against bursting, and for the regulation of the internal force. A very small forcing pump, worked by the beam of the main one near the middle, would supply, by injecting once in two strokes obliquely upwards into one of the pipes, any deficiency from waste of water up the sides of the pistons and by exudation. If it throw in too much, the excess would settle in the small chamber, whence it would run into the cistern of the little pump.

RAILWAY AND CANAL BILLS.—The number of bills for railways in Great Britain deposited this session is 172, of which 129 authorize new works to the extent of 1,129 miles, in the whole of the United Kingdom; besides 95 miles of deviation lines, and 12 projects for enlargement of stations.

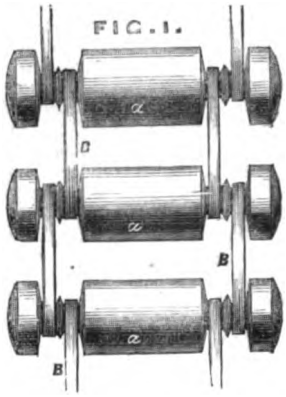
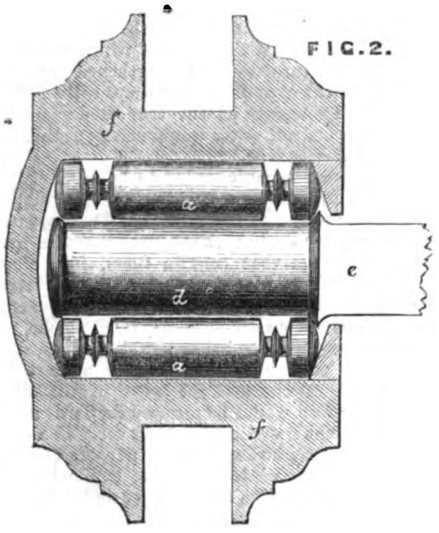
M. BRUSSAUT'S INVENTIONS.

ANTI-FRICTION ROLLERS AND WEIGHING MACHINES.

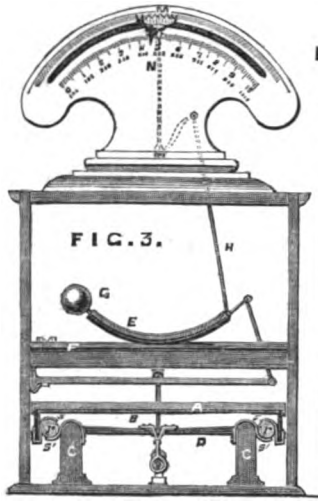
M. BRUSSAUT, a French engineer, whose inventions have been mentioned with great favour in the scientific journals of Paris and Brussels, is now in this country, drawing attention to his improved apparatuses. They comprise, first, a modification of the well-known anti-friction axles, an improved arrangement of which (the invention of Mr. Rowan, of Belfast) was described and illustrated in the MECHANICS' MAGAZINE for June 15, 1844, No. 1088, Vol. 40. The chief feature of M. Brussaut's invention consists in leaving each anti-friction roller free to revolve, and at the same time connecting all the adjacent rollers to each other by small endless belts of vulcanised India-rubber or other suitable material, as shown in Figs. 1 and 2 of the annexed engravings. The rollers are thus allowed all necessary freedom, while rolling action only is produced between the surfaces in contact. In Fig. 1 the rollers *a* and the belts only are shown; in Fig. 2 the rollers are supposed to

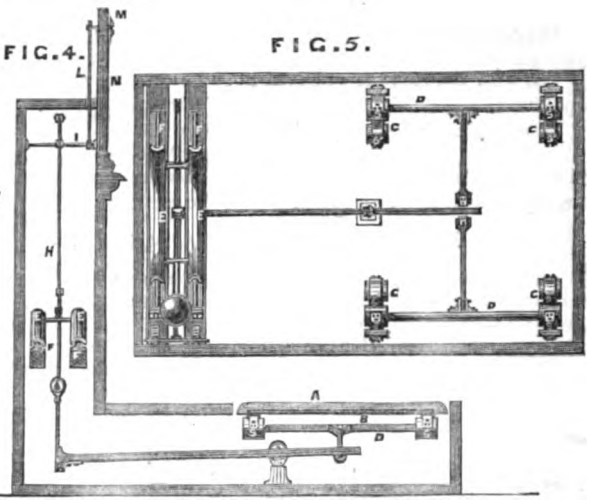


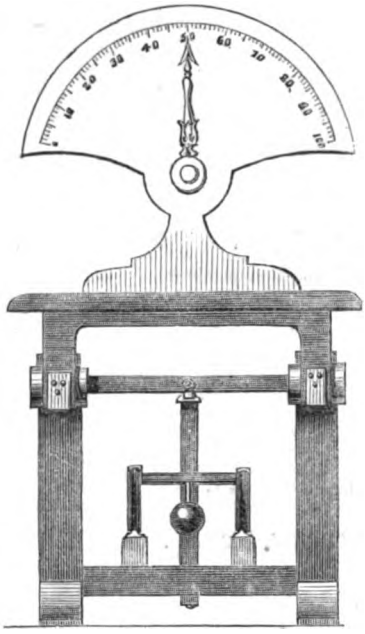


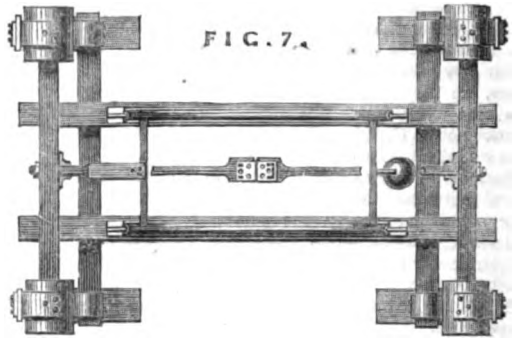
be interposed between the axle-box and axle of a vehicle. In the latter fig. *a a* are the rollers, and *d* is the portion of the axle *e*, which receives the wear; *f* is the axle-box, with which, as well as with the surface of *d*, the rollers *a a* are in contact. By the employment of apparatus of this kind, not only is the friction reduced to an extremely small amount, but lubrication is entirely dispensed with, and yet no heating takes place, even with the highest working velocities, under great pressures.* The apparatus is, of course, applicable, in modified forms, to shafts and axles of all descriptions.

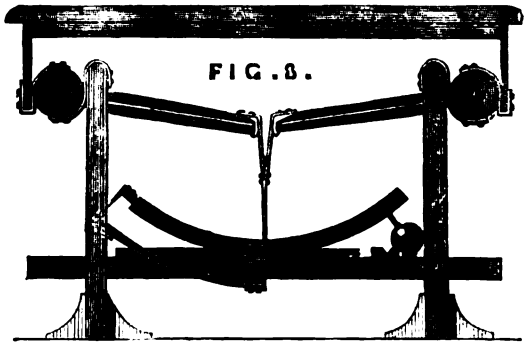
* The giving the anti-friction rollers sufficient strength of resistance in order to prevent their becoming crusted or deformed is simply a matter of proportion. In many cases, however, the diameter of the axle or shaft must be increased; and then Mr. Brussaut employs hollow iron, the superior strength of which is well understood, but the use of which would be impossible with the shafts at present in use, which, so to speak, are merely greased brakes.



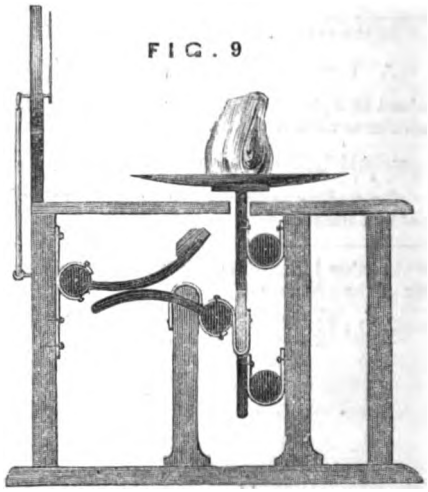








M. Brussaut's inventions next comprise a set of weighing machines in which all coiled springs, moveable weights, &c., are dispensed with. Fig. 3 is a transverse view partly in section, Fig. 4 a longitudinal view partly in section, and Fig. 5 a plain view of one of the improved machines, with the scale, &c., removed. *A* is the scale or weighing platform, supported on the plate *B*, which is carried by the bands *s s*. These bands are attached to short cylinders *r r*, carried by other similar bands *s' s'* secured to the uprights *C C*. To the cylinders *r r* are attached the cross-bars *D D*, which, by means of a series of levers connected and arranged as shown in the engravings, communicate, with the arcs *E E*, which roll on the rails *F F* and have a weight, *G*, fixed at their extremities. From the other end of these arcs a connecting rod, *H*, leads to a crank on the spindle *I*, on which the indicating needle *L* is mounted. This needle carries a vernier *M*, where necessary, in order to indicate the divisions on the card or face *N*, as minutely as may be desired. It will be apparent, from the foregoing description, that when the parts are once properly adjusted, the weight of any article placed on the platform *A*, will be indicated by the needle on the card. The apparatus is found to be exceedingly sensitive. In Figs. 6, 7, and 8, we have shown views of a modified form of the apparatus, in which, although the relative positions of the parts are very different from what they are in the former case, the action is essentially the same. In Fig. 9 we have illustrated an arrangement in which the arcs are employed in a modified manner, adapted for use on a counter.



Digitized by Google

The whole of these machines depend upon the action of the bands, &c., only for the motion of the needle, on the weight being applied, and are therefore but little liable to get out of order. In the various dispositions of parts above described the principle of the apparatus is the same throughout. The absence of all variable or delicate parts renders them peculiarly well fitted for weighing luggage at railway stations, retailed goods, and other like articles.

ON TELEGRAPHIC CABLES.

By Capt. Jasper Selwyn, R.N.

Captain Selwyn, R.N., of Woodland Crag, Grasmere, sends the following able paper for publication. We give it place with much pleasure, not doubting that its value will be duly appreciated:—

Gentlemen,—Believing that where conjectures on nautical matters have to be made, seamen are of all the most fitted to give those conjectures the nearest possible approach to truth, I venture to submit to your readers the belief which I entertain as to the causes of failure in the present Atlantic cable, and the means to be adopted to remedy, and in future to prevent such failures.

The cable, we may assume, was, previously to its being laid, perfect in its insulation, and only gradually, after being laid, ceased to be so. I reject here from consideration the fault said to have been cut out on board the *Agamemnon*, because that does not appear to have affected the first messages; and what I now seek are the causes which were evidently at work shortly after the cable was laid, in diminishing and eventually in destroying the insulation.

I will first show cause against, and attempt to eliminate, two suggestions on this head which have been made, and which do not seem to me, as a seaman, to carry probability with them.

The precipices which mark the deep-sea boundary on both sides have been supposed to be, by the cable sawing over them, causes of injury. Had this been the case, and had the cable in the first week after laying been so injured from this cause as to expose the gutta percha and damage the insulation, no long time could have elapsed before the cable would have been cut through, which does not appear even yet to be the case; and besides, our knowledge, such as it is, of the action of water at that depth does not encourage the idea that any such force is there at work. (I will say in passing that this precipice ought to have been avoided, unless such sudden descents extend much farther under water than they generally do on land. A little more time given to soundings would have been well employed.)

There is next the idea that the water pressure due to the great depth has damaged the insulation. But if that were the case, it would have shown itself in a few hours at most after submersion, and would, (as it would have affected equally, and at the same time, nearly the whole length) have been complete, not partial.

I take these two, because, if really existing it is evident they would be fatal to the whole scheme; but neither I believe is to be feared or lamented. I will now consider those causes which I regard as probable.

In the old Mediterranean cable, which was supposed before its failure to have been laid in a perfect state, and parts of which have been recovered, several "kinks" exist, beginning as in

Fig. 1, and when strained, resembling Fig. 2; and where, from the strain of raising, or from any other force, these, as at Fig. 1, have been partially straightened, the result is that the cable is untwisted, as at Fig. 2, at the point where the "kink" was, and the gutta percha, or even the copper wire, exposed. I believe the existence of these 'kinks" to be the main cause of failure in the Atlantic cable. There is a second possible and indeed probable future cause of failure originating in the construction of the cable itself, which though not so likely to take effect as that to which I have adverted, is still worth considering. It is that a cable with a soft core and rigid exterior is always liable to injury by stretching. Take a length of four-stranded rope which, in a measure, fulfils these conditions, and examine it after having been long in use, or subjected to any considerable strain, and it will be found that the "heart" or "core" has separated into lengths of a few inches, while externally the rope appears perfect. And it is useless to say that in the trials of strength to which the Atlantic telegraph cable was subjected, the outer wire always gave way first; for this will no doubt be the case in short lengths, but not so when the strain is brought on miles at once. Four-stranded rope might be called five stranded, being in fact composed of four outer tightly twisted strands, and an inner central less-twisted soft core, not laid up with, but running straight through the four outer. The result of strain is, of course, that the outer spiral presses on the soft centre, that centre yields to compression, the spiral consequently diminishes in diameter and increases in length, and the centre not doing so proportionably gives way. This would occur the more certainly in proportion as the softer centre occupies a greater space, which in the telegraphic cables is very considerably the case. The cables proposed by Mr. Allan appear to be the only ones which provide for and obviate this fault.

I will now return to the question of "kinks," with the view of showing how they are now caused, and how they may in future be avoided.

Let a common cotton reel be taken, and having smoothly wound about it some narrow tape, let it be set on end on the table. This will fitly represent the state of the coil of cable in the hold of a vessel. If now the tape be taken off, by holding the end, and lifting each turn over the top of the reel (as must be done with the coils of cable) it will be seen that for each turn so taken off a turn has been taken in the tape. It may be said that I am only reversing the operation which took place when the cable was coiled into the vessel, and that the turns then taken in are now taken out (or *vice versâ*.) Granted, but the circumstances are totally different. The pressure of the water, increasing and becoming very great as the cable descends, here manifests itself in the shape of friction, resisting any turning of the cable below. The consequence is, that there is a constant tendency to accumulate turns on that portion of the cable near the stern of the ship. In the *Agamemnon*, accordingly, the cable between the stern and the spot where it entered the water was observed to be constantly in rapid revolution. Now, to see the effect which turns so caused may probably produce, take a piece of whipcord, or any strongly-twisted thread, and after slightly increasing the twist by turning it between the fingers, and while holding it in a nearly vertical position between the two hands, dip the upper hand suddenly two or three inches. The result will be that a "kink" will form. And this is nearly what takes place when the ship pitches in a seaway. Thus, then, kinks may be taken in the cable under water, and without the knowledge or fault of those engaged in the operation.

But if—as I am informed was the case—such an act of suicidal folly be committed as, on arriving in shoal water, to pay over any considerable amount of slack, then the result would inevitably be that the cable so deposited would first take its place on the bottom in the form of coils, which, when the strain of currents or tides inshore, or of the settling in the deep water came upon the cable, would be converted into kinks, destroying the cable, each in proportion to the strain brought upon it, by opening the strands, and exposing the copper wire. The damage thus caused would, theoretically, present all the phases of gradual increase which have actually been observed.

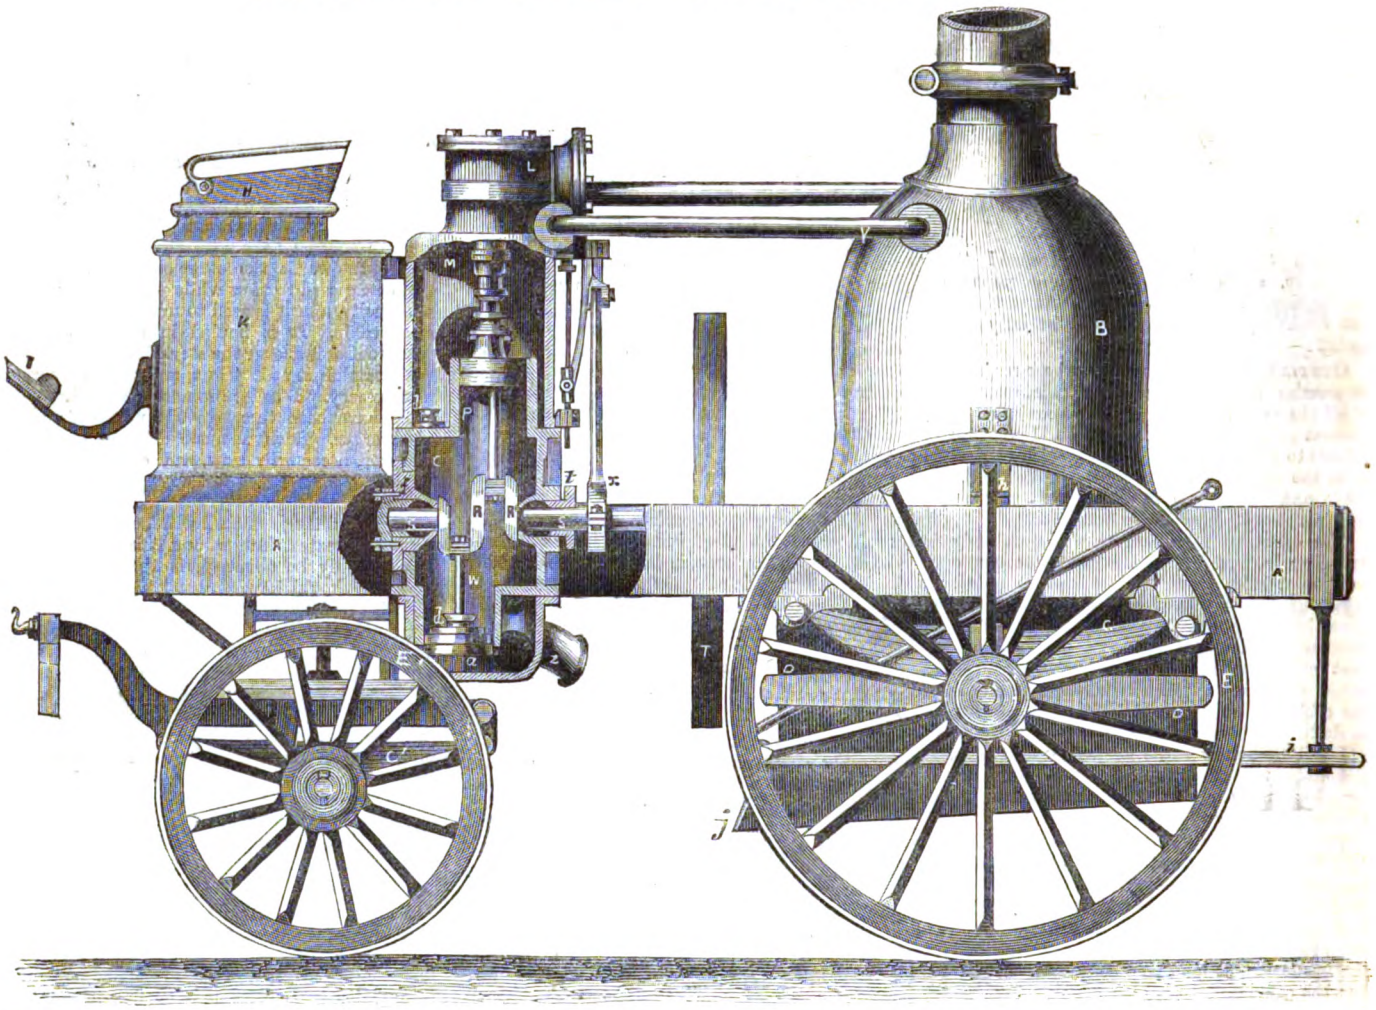
As I have said, I see little reason to doubt that to the existence of these kinks, mostly situated in the comparatively shoal water, may be attributed the present defective state of the cable. I will now proceed to consider how these or any other defects may be remedied.

This can only be done either by raising entirely, or by the operation known to seamen as underrunning, which in its ordinary form may be thus described:—We will suppose that a line or rope has been laid across water between any two points, and that it has sunk to the bottom. It is clear that if a floating body of sufficient size to bear the weight be brought under the rope at one end near the shore, and by any force, say by hauling ahead by the rope, that floating body be impelled towards the other end, the whole rope will be exposed to view while passing over it. So, practically, a boat is used to underrun a hawser or small cable. It is hauled in at the bow, and passes out as fast over the stern, but meanwhile we can examine it as it passes, and stop it for repair if necessary. I believe some twelve miles of the cable have been thus treated and found to be in good order. Such a mode of under-runing is, however, necessarily slow, and could scarcely be employed with effect for any great distance or depth. I propose a different method by means of a large cylinder, which I will hereafter explain. But the greatest danger, and it is one which can but partially be obviated, is that a "kink" or "kinks" should have so weakened the cable as that it shall no longer be able to bear its own weight in water. This indeed might be fatal to any attempt to raise it, but we must hope that such faults will not be in the deepest parts, as in fact, there is every reason to believe. At any rate, the value of the property at stake (about £200,000) is so great that the experiment must be well worth trying; and I believe that if done without loss of time, and either by the method which I propose or by some better one, if that can be found, there is the greatest probability of success in attempting the operation of repairing, or lifting altogether and relaying, the present Atlantic cable.

I have now to explain how I propose to avoid these and other dangers, and facilitate the laying in good condition of future cables. This is to be done by means of large floating cylinders of sheet iron, which it is clear may be of a size proportionate to the weight and thickness of the cable adopted. I will, however, confine myself to the calculations which would be necessary for the present cable. It is proposed to construct two or more cylinders of sheet iron, (if two) the length required will be 60 feet, and diameter 50; roughly calculated as costing £12,000 each. These will each be capable of supporting, at considerably less than half immersion, 1,500 tons (or miles) of the cable to be reeled on the outside like cotton on a bobbin. The cable being of §-inch diameter, the thickness of coils when the whole is reeled on will be about 2 feet 4 inches. There are flanges of this height at each end of the cylinder. It is evident that if the cable so disposed were to be taken to sea, by towing from the axles (as a garden roller is dragged along the walk) and if on arriving in deep water the end were allowed to sink and the cylinders to revolve freely, the whole would run off. But to prevent this, and to act as breaks, to the ends of the cylinder are attached paddle floats or boards. These cause the cylinder to revolve (as the friction of the gravel does with the garden roller) at the rate due to the velocity of the towing vessel, and the circumference of the paddle wheels. They also resist any tendency of the cable, by its own weight, to drag itself off, but only gradually, and as the resisting medium is water, not absolutely but only in proportion to the strain and therefore the velocity of rotation. By a proper proportion of the area of float or paddle board immersed, we can always ensure the turning of the cylinder and consequent release of cable, with a less force than the breaking strain. But the occurrence of such strain can scarcely be expected, because by making the barrel of the cylinder of greater diameter than the paddle wheels which govern the revolutions, a certain

Digitized by Google

SHAND AND MASON'S STEAM FIRE-ENGINE.



easily-regulated amount of slack can be always thrown off at each turn. The electric communication is kept up by passing the *inner* end of the cable as coiled on through one end of the axles, and thence on board the towing vessel, where it is dipped into a cup of mercury.

I will now furnish a list of the advantages which I suppose to be derivable from the use of these cylinders, premising that, with a model made from a 50 gallon cask, with a small line in proportion, in the presence and to the satisfaction of Commander Gibson, R.N., late first lieutenant of the *Agamemnon*, I performed on the lake at Grasmere the operations of laying, under-running, and raising most sucessfully.

Advantages.—1st. The cylinder is the strongest, smallest, and cheapest known form for carrying a given weight in water. 2nd. The coil is nowhere smaller than 50 feet diameter; the cable is, therefore, but little bent. 3rd. Once coiled on from the works, it is never again moved or bent till laid. 4th. The resistance or brake power being derived from the water, is always proportionate to the strain on the cable, and this without any attention being needed. 5th. No extra weight or impediment is placed on board the vessel towing, her safety is not endangered, and though the resistance to towing approaches that of a vessel of the same draught of water, minus the friction, yet this diminishes with every turn of the cable which is thrown off. 6th. The cable is laid without any strain, and with as great a per centage of slack as may be desired, suitable means of expanding or reefing the paddle floats being provided; thus the slack can be increased or diminished at pleasure. 7th. The cylinder can be made to reel up the cable simply by passing the end on the opposite way, and towing as before, or if necessary in circles. 8th. The cable may be laid without danger at whatever speed the towing vessel can accomplish. 9th. The cylinder may be left as a buoy on the cable (the towing vessel lying by it), if from bad weather or any other cause, it be necessary to discontinue the operation for a time. 10th. The whole operation will be less expensive, and the first cost for cylinders will suffice for the laying or repairing many lines. 11th. The cable is little subject to the ordinary risks by fire, leakage, or storms. 12th. It can be coiled on the cylinder with little trouble or expense as fast as the cylinder can be turned in the water, with the floats off, and by means of portable steam engines from the wharf, the cylinder being moored off. 13th. The cable can be laid in almost any weather; nothing but such a gale as would stop the towing vessel, or else ice, would interfere with it. 14th. No twist or kinks can by any means be taken in, as may be seen by experimenting with the tape on a reel, before referred to. 15th. No change in the weights on board the towing vessel takes place, such as was found injurious to the stability of the *Agamemnon*, and nearly caused her loss. 16th. A leak, if existing, could easily be got at, as the cylinder, at each revolution, is in fact turned bottom up, but this need scarcely be feared, as it may be proved by hydraulic pressure before being used. 17th. The cable, instead of being a cause of straining and weakness to the structure carrying it, is, in fact, a source—and a great one—of strength, as, when coiled on the cylinder, its effect, like hoops on a cask, is to bind the whole together. 18th. No heat injurious to the gutta percha, and, therefore, to the insulation, need be feared, which has been found to be the case in the hold of a vessel, and is more to be dreaded in hot climates. 19th. The cylinder is peculiarly adapted to the otherwise difficult task of under-running the cable for repair, or even, if desired, of raising it entirely. 20th. This one machine is capable of accomplishing all that can be needed in laying, under-running, or raising the cable.

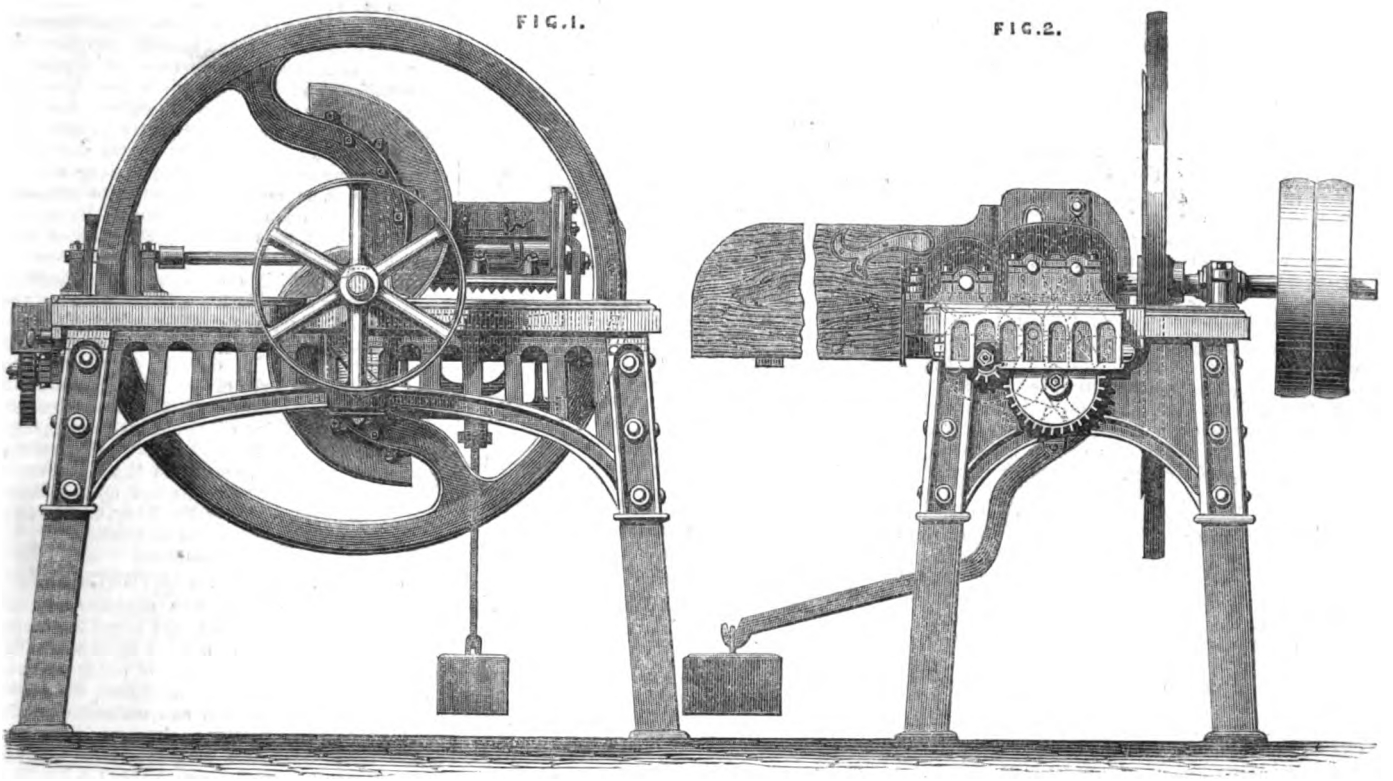
SHAND AND MASON'S STEAM FIRE-ENGINE.

MESSRS SHAND and MASON, the well-known fire-engine manufacturers, of Blackfriars-road, Southwark, have lately introduced a class of steam fire-engines, the first of which was despatched to St. Petersburg a month or two since. As one of these engines is found to deliver as much water in a given time as three engines of like size worked by twenty-eight men each, and as the manufacturers have had great experience in the construction of fire engines—being the makers of the floating Thames engines, among others—we shall now probably make a considerable advance towards the general application of steam to the extinction of fires.

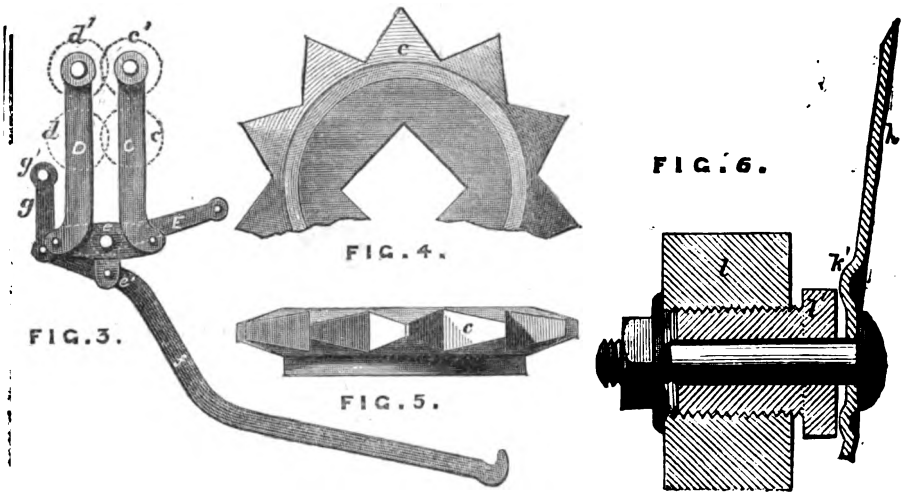
The above engraving represents a side elevation of the engine, with the pumps and details connected therewith shown in section, for the purpose of more clearly illustrating their construction and arrangement. *A* is the main framing of the engine, composed of wood and wrought iron combined, and supporting a vertical tubular or other suitably-formed boiler, *B*. This frame is suspended on suitable bearing springs on the hind axle, which is made to surround, without being in actual contact with, the lower portion of the boiler, suitable arms projecting from each side

Digitized by Google

RICHMOND AND CHANDLER'S IMPROVED MACHINES FOR CUTTING HAY, STRAW, &c.



of this annular part of the axle serving to carry the large hind wheels. *F* is a wrought-iron fore locking carriage, furnished with bearing springs *C'*, wheels *E'*, and a pole or shaft (not shown for horses. Above this front portion of the framing is fixed the driver's seat *H*, and foot board *I*, a box, *K*, beneath the seat serving to contain the hose and implements, or, if preferred, a hose reel. The suction pipes are carried on each side of the framing. The combined steam and fire engine is fixed to the framing, *A*, between the front and hind axles in such a position as to admit of the front wheels locking round freely on a centre. The steam cylinder *L* is cast in one piece with, or is bolted on to, the top of the air vessel *M* in an inverted position, and the piston rod, after passing downwards through a double stuffing box has keyed or otherwise secured on to it the piston of the upper pump, the barrel of which is placed immediately beneath the steam cylinder. The piston and pump thus serve as effectual guides to the piston rod of the steam cylinder. A connecting rod jointed to the underside of the pump piston connects that piston and the piston rod of the steam cylinder with the crank *R*, on the engine shaft *S*, fitted with a fly wheel. This shaft works fluid tight by the aid of the stuffing boxs *t t*, in the casing *c*. The lower pump piston, or bucket working in the lower barrel is connected by the rod *W* with the crank at *R'*, set diametrically opposite to the crank *R* of the upper pump and cylinder, by which means the two pumps will be kept in constant or continuous action. The slide valves of the engine are worked from an eccentric at *x*, another eccentric not shown in the drawing serving to work the boiler feed-pump; another feed-pump to be worked by hand being also provided. Steam is admitted to the steam cylinder from the boiler by the steam pipe, and when the pumps are thereby set simultaneously to work, water is drawn in by means of ordinary flexible suction pipes through one of two inlets *Z* (one of which only is shown in the drawing, the other one being cut away) into the suction air vessel *a*, into the lower pump barrel through the valve in the piston or bucket thereof into the air tight casing *c*, and into the upper pump barrel,



the piston of which forces it through a valve or valves, *d*, into the air vessel *M*, and thence through outlets in the bottom of the air vessel into the hose pipes. In order that the water may be allowed to flow in one direction only through the pumps in place of being driven back through the valve *d* by the descent of the upper pump piston this latter piston may be furnished with a valve or valves similar to those in the lower piston and the valve *d* dispensed with, by which arrangement the water will be lifted in one unvarying direction into the air vessel. The crank may be readily got at for repairs by simply removing the side cover *f* of the casing *c*. The boiler, *B*, is supported on the framing, *A*, by short arms or girders riveted to the boiler sides, and let into the framing on the inner sides; and a bracket piece is also riveted to the boiler on each side, which rests upon the top edge of the framing. *i* is a foot board for the stoker to stand upon, the boiler being stoked from the back end of the engine. A suitable damper is provided at *j* for the purpose of regulating the draught.

RICHMOND AND CHANDLER'S IMPROVED MACHINES FOR CUTTING HAY, STRAW, &c.

MESSRS. RICHMOND & CHANDLER, the well-known agricultural implement makers, of Salford, Manchester, are now introducing a class of improved machines for cutting hay, straw, &c., embodying several patented improvements, which add considerably to their efficiency and durability. Their invention consists, first, in supporting the upper feed rollers of such machines in adjustable bearings, so that each roller can rise or fall independently of the other; secondly, in casting the mouthpiece of cast-steel; thirdly, in making the teeth of the first pair of feed rollers tapered, and radiating from the axis; fourthly, in an improved mode of constructing the knives; and, lastly, in an improved mode of connecting the knives to the fly-wheels or other fixings of such machines.

Fig. 1 is a side-elevation of a chaff-cutting machine to which their improvements are applied; fig. 2 is an end-elevation of the same; fig. 3 is a detached view of the adjustable bearings of the

Digitized by Google

top feeding-rollers; fig. 4 is a detached view of part of the feed-rollers, showing their improved mode of shaping the teeth; fig. 5 is a plan of the same; and fig. 6 is a detached view of the cutting-knife, showing how the same is constructed and connected to the fly-wheel.

In fig. 3, *c* and *d* indicate the two bottom feed-rollers, supported in fixed bearings, as is now customary; and *c'* and *d'* are the top feed-rollers, which are so supported that each can rise or fall independently of the other, according to the depth of the feed. To the axles of the rollers *c'* and *d'* are suspended the links *C* and *D*, the lower ends of which are jointed to the beam *e*; to the centre part of the beam is cast the projection *e'*, to which is jointed the long lever *f*, furnished with a weight; the lever *f* is also jointed to the swing frame *g*, whose fulcrum is at *g'*. To the beam *e* are cast or fixed the levers *E*, the ends of which are jointed to brackets fixed to the under side of the feeding-plate. The mouthpiece consists of a bottom-plate and side-plates, in which are cast slots for the bearings of the top feed-rollers *d'*, and for the cover, which moves up and down with that roller, as is now customary. The mouthpiece is cast of the metal known as cast-steel, the object being to prevent the mouthpiece being injured by the action of the knives, *k*, *k* (fig. 6), which are connected to the fly-wheel *l*, fixed to the main-shaft, revolving in bearings cast to the bed-plate. The feed-rollers are turned round from the main-shaft by a bevel pinion gearing into a bevel wheel, and by the various wheels indicated in the engravings, which do not require to be described in detail, as they are common to machines of this description. On referring to fig. 4, it will be seen that the teeth of the first pair of feed-rollers, *c* and *c'*, are made to radiate from the axis, and that they are taper, as shown in fig. 5, whereas the teeth of the second pair of feed-rollers, *d* and *d'*, are of the usual shape. The improved-shaped teeth of the rollers *c* and *c'* take better hold of the hay, straw, or other vegetable substance to be cut, and consequently convey it more regularly to the second pair of rollers, *d* and *d'*, the teeth of which enter in the spaces between the teeth of the first pair of rollers, and strip them. The teeth of the second pair of feed-rollers are stripped by plates serrated in the usual manner. As it is of the utmost importance in machines for cutting hay, straw, &c., to be able to adjust the knives to the face of the mouthpiece, the patentees construct the knives and connect them to the arms of the fly-wheel or other fixing in the following manner: the blade of the knife *k*, shown in section in fig. 6, is set at an angle to the face of the fly-wheel, as is now customary; each blade is stamped with four or other convenient number of projections, *k'*, the outer faces of which are diagonal to the blade, and in a line with the face of the fly-wheel. The projections *k'* fit against the screwed bushes *l'*, which are furnished with six-sided heads, and are screwed into the arms of the fly-wheel *l*; the bolts *m* pass through the projections *k'* of the knives *k*, through the bushes *l*, and are tightened up against the arms of the fly-wheel, thereby firmly securing the knives. When it is necessary to adjust the cutting edge of the knife, the nuts of the bolts *m* are slackened, and the bushes *l'* are turned round or partly round, either in one direction or the other, to increase or diminish the distance of the cutting-edge of the knife from the face of the mouthpiece, and then the nuts of the bolts *m* are again tightened. By this means the separate adjusting screws usually employed are dispensed with, and the knives are easier to adjust, and more securely attached to the fly-wheel or other fixing than heretofore. In fig. 3 the feed-rollers and the machinery by which they are weighted are shown in the positions they occupy when the machine is not at work, but when the hay, or straw, or other vegetable substance to be cut is supplied, and the machine is set in motion, the top roller *c'* of the first pair of feed-rollers rises, while the top roller *d'* of the second pair of feed rollers will probably remain closer to that below it than the first pair, but each top roller can rise or fall independently of the other, according to the depth of the feed; consequently the pressure between the rollers is at all times equal, and the hay or straw is always securely held between the front pair of rollers, which object could not be obtained in the machines of the ordinary construction, in which both top rollers move simultaneously.

THE MICRO-ELECTRIC TELEGRAPH.

THE Micro-Electric Telegraph recently invented by Mr. Isham Baggs, and for which he has obtained provisional protection, consists of a combination of optical, chemical, and electrical apparatus, and it promises to maintain in a state of permanent efficacy, under all the various conditions of weather and humidity, any line of telegraph, short or long, to which it may be applied. It is very well known that all suspended lines of telegraph are liable to derangement in a humid state of the atmosphere, and that the effective action of the current under these circumstances is greatly weakened,—so much so, that the needles or other indexes of electric communication, are frequently rendered thereby so faint and sluggish in their movements, as to become practically useless. The reason of this is that wherever a mass of matter, great or small, is required to be moved, a certain amount of force is required to move it, and that in proportion as the preponderance of power over friction and other opposing influences is diminished, so is the resulting motion decreased, both in amount and velocity. In other words, an electric current or impulse despatched from London may reach Newcastle or Aberdeen, but in so impaired a state with reference to quantity, as to be unequal to the task of executing its mechanical functions.

In the present invention the movement of particles is substituted for that of masses, so that any quantity of electricity, however minute and otherwise inappreciable, cannot fail to produce a certain corresponding effect. A single wire is the medium of communication, and the earth, as at present, completes the circuit.

The results and their application may be well illustrated by the decomposition of water. If two poles of a corrodable metal are employed for this purpose, hydrogen is given off from the negative, and oxygen absorbed at the positive. Now, as either wire may be rendered negative at pleasure, and the process of making contact repeated with any required velocity, we have only to consider the evolution of the gas from the right or the left hand pole as being equivalent to the right or left hand movement of a magnetic needle, and we have in all respects a chemical counterpart of the existing mechanical telegraph. The indications so given are marked, sudden, and characteristic, and are produceable, as before stated, with the smallest amount of electricity, and therefore under the most disadvantageous conditions.

Let us suppose a case, and assume that we have a long line of telegraph in a most defective state of insulation from wet or otherwise, and that only the one-hundredth part of the electricity dispatched from one terminus is capable of reaching the other; then that one-hundredth part, which will not move a needle or stir a magnetic armature, is still capable of decomposing a definite amount of water, and of liberating a corresponding quantity of gas. Of course the quantity of gas so liberated is very small; still the results are always manifest, for the inventor works the decomposition trough in the focus of a powerful oxy-hydrogen microscope, and throws upon a screen a retracted image of the wires and the liberated bubbles of gas, magnified to the extent of *six millions of times their actual sectional dimensions*. In very extreme cases, this power, great as it is, is made to undergo a further extension, and the gas bubbles so produced are generated under a vacuum, whereby a greatly increased augmentation of volume is realized. Suppose, for instance, the vacuum is equal to half an inch of mercury, then the increase of volume would be sixty times that of the original, and though in such case the increase in sectional area would be only as the square of the cube root of expansion, yet here, as the visibility of the result depends not merely upon length and breadth, but also upon apparent thickness, the true increase of value in the manifestation of the signals is directly as the expansion itself. The effect therefore produced upon the screen is amplified THREE HUNDRED AND SIXTY MILLIONS OF TIMES its actual size when viewed by the naked eye. After stating such a fact as this, it appears to us to be quite unnecessary to dilate upon its application. It simply amounts to this, that wherever the faintest current of electricity traverses an electric wire, it can be rendered visible in its effects, and used as an ever ready and effective substitute under the worst conditions for the existing telegraph. We have illustrated the matter by the adduction of a very extreme case. In ordinary practice an Argand lamp or the light of day, when available, is ample for all purposes, and when the wires are short, or the electricity is abundant, no amplifying power whatever is required. We shall return to the subject again, meantime the invention is about to be publicly demonstrated upon a large scale at the Polytechnic, by Mr. King, the lecturer on natural philosophy at that Institution.

CAPTAIN NORTON'S INVENTIONS.

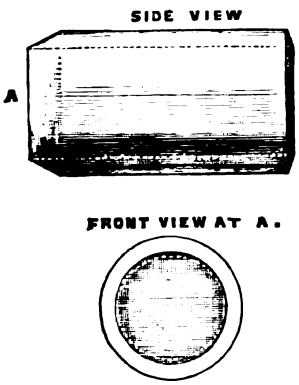
ON Thursday, the 10th, some experiments took place near the field-works of the Royal Engineers at Chatham, for testing some of those admirable inventions of Captain Norton, of which we have frequently made mention. Although the afternoon was exceedingly wet and unfavourable for carrying on the operations, a number of officers of the Royal Engineers were present. The experiments first made were with Captain Norton's liquid-fire rifle-shell. The object of this missile is to set on fire the sails, rigging, and even the hull of any vessel against which it is thrown, and the experiments proved that the shell in question is one of the most extraordinary projectiles ever introduced into the art of warfare. The chemical substance with which the hollow shell is filled, is prepared chiefly with phosphorus dissolved in bi-sulphate of carbon, and is placed in a glass phial within the shell. Immediately on this shell striking any ignitable matter the glass in broken, and so powerful is the liquid that it almost instantaneously sets the object in a blaze. During the experiments yesterday afternoon a number of large sacks were suspended on poles to represent the sails of a ship, and these were soon soaked through with rain so as to become completely saturated. Captain Norton then took a heavy three grooved rifle, of 1 3-16ths inch bore, which he loaded with one of his shells, weighing about 7-oz., the shell sliding down on the cartridge by its own gravity, following the spiral turn of the rifle. Notwithstanding the wetness of the sacking the effect on firing was exceedingly surprising, the liquid spreading through the canvas, which in a short time began to smoulder, and after an interval burst forth into a flame, entirely consuming the whole. Had the sacking been dry the effect would have been instantaneous. Captain Norton undertakes with the same description of shells, but of larger size, to set fire to any line-of-battle-ship in the navy. He now attaches the gossamer cartridge to the base of this shell, thereby expediting the loading, as no ramrod is required. The next experiments undertaken were with a new description of rifle-shot which has been named the "Spinster." This bullet, which can be fired by Captain Norton at a distance of no less than 1,800 yards, is intended for blowing up ammunition waggons, or bags of gunpowder, or setting fire to the camp of an enemy. The bullet, which in shape and size resembles the Enfield rifle-ball, has a chemical substance attached to its base, which becomes ignited the instant it is fired, remaining burning long enough to do the execution for which it is intended. A bag, containing about two pounds' weight of gunpowder, mixed with a great quantity of sawdust, was placed upon

Digitized by Google

the ground, the powder being soon wetted through by the rain. One of the "spinster" shots was fired at the mass by means of Captain Norton's gossamer seemless cartridge, but owing to the powder being so wet no immediate result followed as the gunpowder was mixed up with the sawdust' After a short time, however, the powder was ignited and blown up. Captain Norton afterwards exhibited some of his "frictional igniters," which are a kind of hand grenade, and can be made to explode when thrown from a glacis in the face of assailants. The frictional igniters are for firing grenades at any spot, or at any distance required. They may be had, on previous notice, of the principal London gunmakers. The use of the gallant Captain's frictional grenades (upon which Captain Lempriere reports very favourably), thrown from the towers of parish churches would convert all the villages in England into so many Hugomonts. For the hand grenades used in the defence of posts they are invaluable, as they do away with all risk of accidental explosion in the hands of those about to throw them—a thing, under the present system, of not unfrequent occurrence, owing to defective fuzes. In the defence of works the frictional igniter can be made to explode at any height from the bottom of the ditch, and thus prevent the possibility of the grenade being thrown back into the work by the attacking force before it explodes. The engineer officers present expressed themselves in satisfactory terms at the result of the experiments made with Captain Norton's inventions.

CAPTAIN NORTON'S RIFLE BULLETS.

THE steel cutter represented in the annexed engraving has the section of Lancaster's rifle bevelled at one end, where it has a sharp edge, and is designed for forming the bullet shaft. A piece of



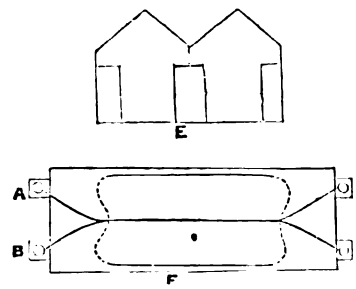
seasoned willow wood is cut to the length required for the shaft of the shot, which may be from an inch to two or more inches in length; the cutter being placed on it so as to run with its grain, is then struck with a mallet till the shaft is formed. The shaft having one end formed somewhat smaller with a rectangular stud, or short pillar, is then placed in the base of the mould, and the molten lead is poured in at the head; the stud having a groove round its base the head holds fast on. The shaft may be forced or swedged through a section of the elliptic barrel a size less than the cutters, which makes it smooth and more dense.—J. NORTON.

CUNNINGHAM'S PATENT TOPSAILS.—The following extract from the Meteorological Register of the barque *Victory*, from the coast of Africa to Bristol, illustrates the utility of Mr. Cunningham's system of sails:—"Wednesday, Jan. 19th, 1858, lat. 38° N., long. 38° W. At 7·30 p.m., the wind shifted suddenly from S.W. to N.N.W. in a very violent squall with ice like rain; as it did not give us the usual amount of warning, and we were carrying a press of canvass to keep clear of the sea, we might have been dismasted had we not been fitted with Cunningham's invaluable patent which enabled us to be under close reefed topsails in about three minutes, and that in a 'certain measure unprepared.'"

HANDS' PATENT FOR DRYING CHAMBERS.

MR. HANDS, of Epsom, of whose valuable process of drying we had occasion to speak in terms of praise some time ago, has been actively employed throughout Great Britain and the Continent in raising kilns and other buildings for dessicating various materials—animal, vegetable, and mineral. Mr. Hands has recently erected a factory on the banks of the River Maeler, leading to Stockholm, and about 20 miles from Gothenburg, Sweden, for the manufacture of bricks, tiles, pipes, pottery, &c. The four kilns hold 35,000 bricks each, forming a complete factory, being so arranged that they all work into one flue down the centre of one drying shed. The middle flue divides the shed into two, consequently they are both always hot from the radiation, and by means of dampers the action is reversed, and a heat of 130 degrees and upwards is thrown on either side at pleasure.

For instance, *E* is a section of the drying-room. *F* is a plan showing the alternate working of the kilns, one being burnt every three days throughout the year; *A* is burning; *B* is cooling; *C* is filling, and *D* emptying.



By an arrangement in connection with the passage leading to the consumer or exhausted receiver in the kiln, through which all the humid atmosphere is drawn from the drying chamber as required—a damper regulating the same—the manufacture of plastic ware can go on in all weathers and in all seasons under this system of heating and ventilating. Mr. Hands was engineer and managing director of the whole fabric, and he is about to build four more kilns at the same place.

SUPERHEATING STEAM.

THE following references were omitted from Mr. Taplin's letter on the above subject in our last number:—*A*, boiler; *B*, water; *C*, steam; *D*, chimney; *E*, superheating chamber; *F*, pipe to convey steam from boiler to superheating chamber; *G*, pipe communicating with the cylinder to supply it with dry superheated steam; *H*, damper; *I*, furnace; *K*, safty-valve. Common steam produced in the boiler *A* ascends the steam pipe *F F*, and passes freely into the superheating chamber *E E*, where it is converted into dry transparent superheated steam, and passes out through the pipe *G*, as such into the steam cylinder. The boiler was designed in 1827, by Mr. Taplin, then of Her Majesty's Dockyard, Portsmouth, and used by him on several occasions for practically illustrating a series of lectures on "Steam and the Steam Engine."

DOCK YARD APPOINTMENT.—We understand that Mr. G. L. Cole, Measurer, of Woolwich, and late Foreman of Caulkers at Malta, is to be reinstated in that capacity at Portsmouth, in place of Mr. Baker, recommended for superannuation.

FLOATING BATTERIES.—"I am informed," says the Paris correspondent of the *Times*, "that six floating batteries are about to be constructed in the French ports on the model of the Gemappes. The batteries about to be constructed are different from those employed in the Crimean war, inasmuch as they are not flat-bottomed and may be navigated like ships." We may state that (as some of our ship-builders know) our Admiralty are not inactive in the matter.

NOTICES.

The following articles and letters stand over until next week:—

The Case of Henry Cort.
Mr. Foster's paper on New Metal Aluminium.
Mr. Hall's letter on Telegraphic Cables.
Chromo-Lithographs.
Patent Law Reform.
New Dock at Port Louis.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 6d. per line for any number of insertions less than 13; for 13 insertions, 5d. per line; and for 52 insertions, 4d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can be received after 5 o'clock on Thursday evening for the ensuing number.

CORRESPONDENT'S QUERY.

GENTLEMEN,—Is there anything novel in the following matter? I have not been able to find an explanation of it in any work on electro-magnetism to which I have access.

I have a coil machine arranged to stand upright on three feet; the hammer for breaking contact is placed underneath it, immediately below the cord, which can be shifted up and down to any required distance from the hammer. Some days since I was experimenting with it, having two cells of a Callan's battery attached, the core being about two inches above the hammer to make it vibrate slowly; happening to touch the top of the core with a pair of pliers which I had in my hand, I was surprised to find the hammer commence to vibrate quickly; removing the pliers, it returned to its former speed. I then substituted for the pliers pieces of soft iron of various dimensions, and found that the application of a piece of iron, however small, had always the effect of quickening the vibration; I should say that the speed was trebled. The core was composed of several pieces of thick iron wire insulated. A solid soft iron core gave the same result.

I am, Sir, your obedient servant,
Cork, February 3, 1859. T. C. H.

EXPECTATION OF LIFE.—A paper on this subject by Mr. Charles M. Willich was read at the Institute of Actuaries on the 31st ultimo. Mr. Willich gives for the expectation of life at any age (a) from 5 to 60, the simple formula, $e = \frac{2}{3}(80 - a)$; or in words, the expectation is = to two-thirds of the difference between the age of the party and 80. This formula is easily recollected, and the results correspond very closely with those obtained from Dr. Farr's English Life Table; indeed so closely, as to raise the question whether the law may not be as true as the result from such an immense mass of returns as those of all England and Wales.

CURRENT EVENTS

IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

[COMPILED BY OUR OWN CORRESPONDENT.]

Stockton and Darlington Railway: Good Profits—Houses on the Stour Valley Railway—Inspectors' of Factories Reports: Infringements of the Act! Number of Accidents and Prosecutions—Training Ship at Liverpool—Tyne Commissioners and the Dues—Second Reading of the Mersey Docks and Harbour Bill—Strike of Stonemasons—Machines for Boot-making at Northampton and Stafford—Gunboats for Egypt—Isle of Man Telegraph—Proposed Wedgwood Monument and Institute—Suggested Monument to Watt at Soho—Bursting of a Canal—Iron Safe and Burglars—Bursting of a Steam Boiler—Fatal Explosion of Gunpowder—Horse Shoe Machine—Engines for War Steamers.

A HALF-YEARLY meeting of the Stockton and Darlington Railway Company was held on Monday. During the past six months the trade had considerably increased upon the previous period and also upon the corresponding six months. The receipts of the first week in Feb., this year, were more than those of 1858 by £1,800. The available balance for the payment of dividends was £37,000; and this after the payment of all the interest and the preference dividends. There was declared on the ordinary shares of the Company a dividend of 9½ per cent. payable on the 23rd inst.——Thirty-one houses have been built through the exertions of the Marquis of Chandos upon the Stour Valley branch of the London and North Western Railway for the use of the station masters and other *employés*. The number is to be increased in spring, until all the servants on that branch between Birmingham and Wolverhampton shall have a dwelling apart from the places of abode of the mass of the South Staffordshire people—an event which, in his lordship's estimation, will tend to the increased discipline of the officials.——The reports of the inspectors of factories issued on Tuesday last, draw prominent attention to the infringement of the act in Mr. Horner's (the Manchester) district especially, and urge the Home Secretary to prepare an amending act to prevent such evasions. In Mr. Horner's district the accidents arising from machinery during the half-year were 924, of which 120 were to children and 396 to "young persons." The cases of prosecution numbered upwards of 70.——At the Burnley petty sessions on Monday there were 67 cases of working 12 minutes over-time preferred by the sub-inspector against Messrs. E. and H. Rawlinson, and convictions taken by arrangement.——The training ship *Conway*, for which the Liverpool Mercantile Marine Association have been so long in treaty with the Admiralty, has arrived in the Mersey. The *Conway* is a 26-gun ship, and has been fitted-up expressly for the purpose of a training ship for young sailors.——The Tyne Commissioners have resolved, first, "That this Commission do petition Parliament, and also memorialise the Government, in favour of the abolition of passing tolls, and for the transfer to the respective harbour authorities of all dues levied on ships, and goods carried in ships, in such harbours." And next, "That another attempt be made to obtain an amicable settlement of the Tyne dues."——In the House of Commons on Monday night, after some discussion upon the Mersey Docks and Harbour Bill, the second reading of that measure was carried by a large majority.——The stonemasons at Halifax are at present on strike, in consequence of a disagreement on the question of wages with their employers.——Some of the principal firms among the boot and shoe manufacturers of Northampton advertised to their men, that on the 14th of the month they should introduce machine-sown tops into their trade, as "any further delay in the introduction of sewing-machines" by the masters would be permanently injurious to the trade generally.——The bootmakers of Stafford have followed up this notice by one of their own, in which they say after its expiration they shall take on no fresh hands, thereby indicating their sympathy with their Northampton brethren.——The firm of R. Smaile and Co., of Newcastle-upon-Tyne, have in hand an order for crucibles for Egypt, ordered through the firm of Messrs. R. Stephenson and Co., engineers.——*Mona's Herald* understands that the whole of the capital required for the Isle of Man telegraph has been subscribed, and that a sample cable has been fixed upon by the Provisional Committee.——The respective schemes for commemorating the genius and worth of Wedgwood seem to pretty signally divide public favour. For the statue £2,000, and for the institute £1,900. A model of the proposed statue has been exhibited at Stoke-upon-Trent.——Correspondents to Birmingham papers are suggesting a movement to erect a monument that shall "point out to railway travellers where the celebrated Watt lived and died."——Fifty million gallons of water, weighing upwards of 200,000 tons, escaped upon and greatly damaged the surrounding land, from the Dearne and Dove canal, at Barnsley, on Friday. The crevice from which the water ran was 25 feet below the level of the canal bottom, which was considerably above the valley through which it ran.——Burglars at Halifax last week are supposed to have made a desperate two-hours' attack upon one of the case-hardened safes of Mr. G. Price, of the Clevland Works, Wolverhampton, but without being able to open it.——A large cylindrical boiler went off last week at the Dan Lane factory, Atherton, and seriously injured four persons.—Three children of a butty collier of Wednesbury, in Staffordshire, went with a light into an out-building where their father kept blasting powder; a spark from the candle ignited the powder. One child was killed, and the other two were seriously injured.——The horse-shoe making machine (1847 patent) of Mr. Burden, of Troy, State of New York, has been temporarily erected for the purposes of the inventor at the Chillington Ironworks, Wolverhampton. The machine is alleged to be capable of turning out perfect shoes per minute.——The *Daily News* city article says, we are informed that Government have given out orders for the construction of sixteen engines destined for war steamers.

NOTES FROM THE EASTERN DISTRICTS.

[FROM OUR OWN CORRESPONDENT.]

Bedford, Potton, and Cambridge Railway—Proposed new Town Hall at Cambridge—Observatory at Bury St. Edmunds—Colne Valley and Halstead Railway—English Agricultural Engines in Russia—Gas in Houses, &c.—The Dams in the Nene: another chapter—Norfolk Estuary Works—The Non-gremial Examinations of the University of Cambridge.

THE proposed new Bedford, Potton, and Cambridge Railway has received hearty support at a public meeting called in the latter town. As usual on such occasions, there was a good deal of grumbling at the management of the Eastern Counties Railway. The proposed line will facilitate communication between Cambridge and Oxford and the Midland Counties.——A new town hall is proposed at Cambridge; £4,000 is required, and promises for £3,000 have been obtained.——An observatory is about to be constructed on the roof of the Bury St. Edmund's Athenæum.——The works on the Colne Valley and Halstead Railway are advancing rapidly towards completion. An engine can now run from Chapel (on the Sudbury branch of the Eastern Counties) to Blue-bridge, near Halstead. The line will be opened for traffic in a few weeks.——Mr. J. Shuttleworth, of the important firm of Clayton and Shuttleworth, who have turned out such large quantities of agricultural engines of late years at Lincoln, has left that town for Russia, for the purpose, it is understood, of devoting his personal attention to the development of a trade with the agriculturists of that empire. Mr. Shuttleworth will visit Moscow and St. Petersburg.——At Rétford, Messrs. H. and F. Bailey are reported to have invented an apparatus for making gas, applicable for gentlemen's residences, farms, railway stations, villages, &c., in an improved manner. The apparatus, it is stated, can be managed by a person of little experience in gas matters, while it occupies a small space, &c.——The MECHANICS' MAGAZINE of last week noticed under this head the odd manner in which the dams placed in the Nene by the Nene Valley Commissioners had been removed by certain parties connected with Wisbeach. Of course the Commissioners could not permit these doings to pass without notice; and eleven persons, some of them well to do in the world, have been charged before the Isle of Ely magistrates (under the 7th and 8th Geo. IV., cap. 30) with having unlawfully, maliciously, and feloniously thrown down the Waldersea dam, the same being the goods and chattels of the Commissioners. A number of witnesses were examined, and the proceedings were protracted over seven hours. The bench decided that there was not a case of felony against the defendants, but intimated that they had committed an unjustifiable act. It was stated that the defendants would be required to enter into recognizances in £50 each for the next twelve months. The counsel for the defence objected to recognizances being entered into, and stated that those who instructed him would bring the matter forward at the Assizes. One of the magistrates afterwards said—the defendants promising to do nothing irregularly in future—that although the bench had the power to require recognizances, they did not care to exercise it. The chairman of the bench told Mr. Shelford, C.E., the acting superintendent of works for the Commissioners, that whatever orders might come from Mr. Fowler, chief engineer, the dam at Waldersea must not be re-constructed; the country would not stand it. These dams—if one may credit the statements made on the subject—certainly appear to have been a very serious grievance to the port of Wisbeach, the dues having fallen off in consequence of the impediments offered to free navigation.——It appears that Messrs. Peto and Betts have given up their contract for the Norfolk Estuary Works, as they contend that it is impracticable to carry out the arrangements contemplated without some modification of the plans, to which the company will not agree. The directors have received a tender from Mr. Sissons, of Hull, for the completion of the works, and Messrs. Peto and Betts will pay over the difference between the amount of their contract for the work in question and the amount of Mr. Sissons' tender. During the last half-year about 550 acres of land have been reclaimed, and the first sale of land is expected next year.——As considerable interest attaches to the non-gremial examinations instituted by the universities, it may be desirable to show how the experiment has succeeded at Cambridge. The whole number of students examined at the towns selected—Birmingham, Brighton, Bristol, Cambridge, Grantham, Liverpool, London, and Norwich—was 386; and of these 106 have obtained honours, or 27·46 per cent. of the whole number. As regards the remainder 134 have "satisfied the examiners" but are not included in the honour classes. There remain, therefore, 146 youths of whom no account is given. The towns which have come out of the ordeal the best in proportion to the number of candidates are Liverpool and Grantham. Norwich cuts the worst figure of all.

NOTES FROM THE SOUTH WEST.

[FROM OUR OWN CORRESPONDENT.]

South Devon and Tavistock Railway—Telegraph from France to the Channel Islands—The Electric Telegraph at Plymouth—Timber Contract—Dublin and Bristol: Relative Trade—Cotton Works hinted at at Bristol—New Landing Stage—West Somerset Railway—The Brighton and South Western Dispute—Southampton Docks—The Vanderbilt Line of Steamers—The Transport of Troops to India—The Australian Mail Contract of the P. and O. Company—Water Supply in case of Fire at Southsea—Winchester Barracks—Lymington Railway—Naval Matters.

THE works on the South Devon and Tavistock Railway are in such an advanced state that the opening of the line is expected to take place early in the spring. The Grenafen tunnel—a work of some difficulty in consequence of the nature of the ground—is not yet finished, but is reported to be progressing very satisfactorily.——The French Government has granted a subvention of a line of telegraph from the French capital to the Channel Islands. The British Government must consent, however, before the arrangement can be carried out.——The Plymouth Chamber of Commerce have held a special meeting to consider a letter from the Electric Telegraph Company with reference to the want of additional accommodation for rendering telegraphic communications from the eastern part of the town. They say they could not incur the expense of laying down wires, but if the inhabitants would do that, they would maintain a proper staff. The Chamber agreed to contribute £50 towards the establishment of a branch office in the exchange, or its neighbourhood.——The Government contract for the supply of English oak, rough-sided, thick stuff, and plank for the years 1859, 1860, and 1861, has been taken by Mr. Murry Marshall, the contractor for the three previous years.——It might be thought that the port of Dublin did a more extensive trade than Bristol, but this, as appears from the following figures, is not the case. In 1858, 452 British ships with an aggregate tonnage of 105,372 tons, and 394 foreign vessels with an aggregate tonnage of 93,747 tons, entered Bristol; while 147 British vessels with an aggregate tonnage of 37,705 tons, and 74 foreign vessels with an aggregate tonnage of 27,397 tons, cleared outwards. In the same year, 305 British ships with an aggregate tonnage of 67,711 tons, and 258 foreign ships with an aggregate tonnage of 51,223 tons, entered Dublin; while 43 British ships with an aggregate tonnage of 10,405 tons, and 14 foreign ships, cleared outwards.——A power-loom, exhibited at the Bristol Athenæum, has found a purchaser in that city. The loom, which obtained a prize at the Great Exhibition in Hyde Park, was subsequently hired by Lanca-hire and Cheshire manufacturers, who took it as a model by which to improve their own looms. It was also hired at the Great Western Cotton Works for the same purpose. A correspondent of a local journal ingeniously argues that this loom may prove the nucleus of a new cotton works in Bristol, and that the town is well suited for such an undertaking.——A new landing stage at the Hotwells, Bristol, is now ready for opening.——A public meeting, held at the Egremont Arms Hotel, Williton, Sir Peregrine Acland in the chair, has adopted a resolution to the effect that those present earnestly desired the construction and completion of the West Somerset Railway, and pledged themselves to use their utmost exertions to aid the directors in their efforts to raise the further sum necessary for this purpose. It is understood that arrangements are in progress for an early commencement of the works.——It seems that the dispute between the Brighton and South-Western Companies, with reference to the Ports-mouth traffic, is not yet at an end. The question will come before an equity court on the Wednesday before Good Friday. The defendants (the South-Western and Portsmouth Companies) are to keep an account, in the meantime, of the traffic on the disputed portion of line, and, after payment of working expenses, to hold the balance to be applied in whatever manner may be directed.——It was stated at a meeting held a day or two since that the Southampton Dock Company has, since its formation, expended £700,000 in the construction of docks at that port.——The first steamer this season on the Bremen and New York line *(Vanderbilt)* will leave Southampton on the 22nd inst.——A proposal made by Messrs. Croskey and Co. to the Government for the employment of the vessels of the European and American Steam Shipping Company in the transport of troops to India has not been adopted.——The March Australian mail will be despatched from Southampton in the Peninsular and Oriental Company's steamer *Indus*. This will be the first despatch under the contract recently concluded with the company.——A meeting of the ratepayers of Southsea has been held to consider the adoption of the best means for securing with certainty, and instantaneously, an ample supply of water in case of fire. In the course of the proceedings, Mr. R. W. Ford, clerk to the new water-works company, stated that within the year the great reservoir on Portsdown Hill, and the enlarged mains, with a constant supply of water at all times, would be brought into operation. At present there were between 30 and 40 fire-plugs in Port-mouth, and between 40 and 50 in Portsea; but in Landport and Southsea there were none at all. Resolutions were passed to the effect that an engine and fire-escape should be obtained in every district, in addition to the supply of water.——Some improvements are in progress at Winchester Barracks. New quarters are to be erected for married soldiers; the foundations are to be completed by the end of March.——The Lymington Railway Company are applying to Parliament for power to raise an additional £13,000 to enable them to build a new and more commodious station, and to complete other improvements now in progress. The dividend declared at the half-yearly meeting just held was at the rate of 2 per cent. per annum.——Continued activity prevails in Chatham Dockyard in consequence of the approaching launches in April. The *Hood*, 93—92 broadsiders and one pivot gun—and the *Charybdis*, 20, screw-corvette, will, it is expected, be the first vessels launched. The engines of the *Hood* will be of 600-horse power.

NOTES FROM SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

Shipbuilding on the Clyde; the "Bohemian" steamer—The Pig Iron Trade—Coals—Importation of Valonia—The Steam Plough in Stirlingshire—Monklands Railway—The approaching meeting of the British Association at Aberdeen—Highland and Agricultural Society; the condition of the labouring classes—Improvements at Leith—Loss of the "Ignez de Castro" steamer—Scottish Railway, &c., Bills in Parliament.

THERE is some improvement noticed in the shipbuilding trade of the Clyde. Messrs. Laurence, Hill, and Co., of Port Glasgow-road, have received an order to commence an iron steamer for the Londonderry trade. At Greenock nine iron steamers are in course of construction in the various

Digitized by Google

yards, and five wooden vessels. Messrs. Caird and Co. have five pairs of engines on hand, and are repairing the *Teutonia* (s. s.). Messrs. M'Nab and Co. are engaged on three pairs of engines, and in executing some repairs in sugar-houses. Messrs. Smith and Co., Port Glasgow-road, are also executing machinery for sugar-mills in the West Indies. Messrs. Denny and Brothers, Dumbarton, have just launched a handsome iron screw steamer of 2,200 tons for the Montreal Steam Ship Company's line. This fine vessel is the fourth of the same size which has been launched from the yard for the same owners within the last ten months. The new vessel, which has been named the *Bohemian*, is 300 feet in length, and will be fitted with engines of 300-horse power by Messrs. Tulloch and Denny, Dumbarton. The *Bohemian* will afford accommodation for 450 first and second-class passengers. ——The Glasgow pig iron market was flat and dull up to Saturday. On that day, however, the market stiffened, and up to Tuesday had slightly recovered.——In coals no change is reported. ——The brigantine, *Henry Curwen*, from Smyrna, and *Scala Nova* has landed in Victoria harbour, Greenock, 150 tons of valonia, the first cargo of the article ever brought into the port. Valonia is the modern name adopted for a species of acorn exported from the Morea and the Levant for the use of tanners. One of its chief excellencies is that it makes leather impervious to moisture. It is said to be rising into favour with the trade. ——A successful—and what is more important still, economically successful—trial has been made with Fowler's steam plough, near Stirling. The committee of judges estimate the daily expense of a steam plough at £2 2s., or £12 12s. per week, allowing, however, time for removal, short days and wet weather, four days a week are reckoned as the average of working time for a steam plough throughout the year; and the judges, therefore, deduct from the £12 12s. two day's coal and water, £1 6s. For the net expenditure of £11 6s., they consider 35 acres would be ploughed, while the expense of ploughing the same quantity of land by horses would, they state, be £15 6s. 3d., leaving a balance of £4 3d. in favour of steam. The judges note that the work performed by the steam plough was equal to anything done by the common plough. ——The dividend of the Monklands' Railway Company is at the rate of 8 per cent. per annum. The working expenses and charges have been reduced £1,678 as compared with the corresponding half-year of 1857.——With regard to the approaching meeting of the British Association at Aberdeen, it may be interesting to state that the colleges have tendered every facility in their power to the Association for the transaction of its business. The forenoon meetings of the various sections will probably be held in Marischal College, which contains ample accommodation for all the departments. It is proposed to form a collection to illustrate the natural history of the extensive district from the Forth to the Shetland Isles; and the Music Hall rooms will contain an exhibition of portraits and other objects illustrating the history and antiquities of Aberdeenshire. Other arrangements are also being matured.——The late meeting of the Highland and Agricultural Society at Aberdeen is refered to, in point of numbers and excellence of stock and implements, as the most successful ever held under the auspices of the Society. The condition of the labouring classes and their cottages is engaging the attention of this Society. ——Works for a new graving dock have been commenced at Leith. The contractor (Mr. Wilson) has brought forward the necessary plant, driven two long rows of piles seaward of the site of the dock, and laid on the top a line of rails for waggons to be used in conveying stones for a stone bulwark to be made for the protection of the dock, and another line for a travelling crane. A great part of the excavation will be through sand, and the water springing up through it is expected to prove a serious obstacle. To meet this difficulty a steam engine of 150 horse-power is being erected. The works on the Leith branch of the North British Railway are also advancing, and it is believed that it will be opened for locomotives in the course of next month.——Intelligence has been received in Glasgow of the loss of the screw steamer *Ignez de Castro*, one of the vessels of the Glasgow and Lisbon Steam Packet Company. ——The following is a list of the principal private Scottish Bills before Parliament:—Glasgow Public Parks; Galleries of Art; Tweed Fisheries; Forth and Clyde and Navigation; Charlestown Railway and Harbour; Perth, Kinross, and Fife Roads; Maybole and Girvan Railway; Fudborn Harbour; Kirkwall Harbour; Border Union (North British) Railway; North British and Selkirk and Galashiels Railways; Glasgow Corporation Water; Dundee and Newtyle Railway; Border Counties Railway; Banff, Macduff, and Turriff Junction Railway; Formartine and Buchan Railway; Great North of Scotland Railway; Caledonian Railway (to enable the company to make branches to the Wilson-town mineral fields); Carlisle, Langholm, and Hawick Railway; Castle-Douglas and Dumfries Railway; Scottish Central Railway, &c.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated December 22, 1858.

2920. R. Clegg, of Islington, F. Angerstein, of Kennington, and G. Ferry, of Hackney. Improved mechanism for imparting reciprocating motion to machinery, and more especially pumps.

2924. M. Renney, of Dublin, Mechanical Engineer. Improvements in bridges.

Dated January 8, 1859.

68. E. Cobbold, of Hendon, Gentleman. Improvements in instruments for writing and marking, and for the preparation of certain substances for conversion into instruments for writing and marking, and for the application to useful purposes of certain products, arising from preparation aforesaid.

Dated January 19, 1859.

160. P. A. Sparre, of Stockholm. Improvements in the manufacture of paper, suitable for bank-notes, cheques, bills, and similar articles.

Dated January 21, 1859.

190. C. O'Hara, of Toronto, Canada, Esq. Improvements in propellers, for propelling steam-boats, ships, and vessels.

Dated January 22, 1859.

202. B. Templar, of Bristol, Dyer. Improvements in umbrellas and parasols.

204. M. Henry, of Fleet-st.. Improvements in machinery or apparatus for manufacturing corks and bungs. A communication from Messrs. Dalverny and Thouzellier.

206. T. W. Rammell, of Spring-gardens, Civil Engineer. Improvements in atmospheric propulsion, and the structures, tubes, machinery, and apparatus applicable thereto.

208. R. Barter, of Blarney, Cork, Doctor of Medicine. Improvements in heating and ventilating buildings, and in apparatus connected therewith.

Dated January 24, 1859.

209. W. C. Homersham, of Adelphi-terrace, Civil Engineer. Improvements in floating gridirons or stages for repairing ships or other vessels.

210. R. Mushet, of Coleford, Metallurgist. Improvements in the manufacture of cast steel and iron.

211. R. Mushet, of Coleford, Metallurgist. An improvement in the manufacture of cast steel.

212. R. A. Brooman, of 166 Fleet-st., E.C., Patent Agent. Improvements in pumps. A communication from F. Ruff, Paris.

213. J. Laubereau, of Paris, Civil Engineer. Improvements in air engines.

214. J. and W. H. Smith, of City-road, Manufacturers. Certain improvements in manufacturing paper, and in producing watermarks, patterns, figures, letters, and devices thereon, and in the construction of the mechanism employed therein.

215. J. Savory, and W. R. Barker, of New Bond-st., Chemists. Improvements in bottles for medicines and poisons.

216. J. Fowler, jun., of Cornhill, R. Burton, of Kingsland, D Greig, of New Cross, and J. Head, of Newcastle-on-Tyne. Improvements in agricultural implements, and in apparatus used for hauling agricultural implements by steam power.

217. A. Warner, of Threadneedle-st., and W. Tooth, of Southwark. Improvements in the manufactnre of iron, and gases for such and other uses.

218. J. G. Proger, and D. Davies, of Cardiff. Improvements in lanterns used on board ship to signal to the steersman.

219. Earl of Caithness, of Hill-st., Middlesex. Improvements in parts of the permanent way of railways.

220. M. Swan, of St. John's Wood, Civil Engineer. Improvements in ballasting ships, applicable also to the extinguishing fires on board ships.

221. William Tasker, jun., of Waterloo Iron Works, near Andover, Engineer. Improvements in ploughs.

Dated January 25, 1859.

223. J. H. Johnson, of Lincoln's-inn-fields. Improvements in machinery or apparatus for cutting and shaping wood. A communication from P. H. Niles.

224. R. Bodmer, of Thavies' Inn. Improved resin and resinous substances. A communication from J. Creuseton.

225. W. Cutts, of Oldham, Engineer. Improvements in the manufacture of bobbins, spools, and cop tubes, and in the machinery employed therein.

226. W. and H. Hodgson, of Bradford, York, Tool Makers. Improvements in machinery or apparatus for preparing and spinning wool and other fibrous substances.

227. J. White, of Finchley, Surgeon. Improvements in means or apparatus to facilitate respiration under water, or under the influence of fire, or in other situations where an artificial supply of air may be required, part of which improvements is also adapted to facilitate movements in or upon the surface of water.

228. W. Andrews, of Cornhill, Engineer of the Submarine Telegraph Co. Improvements in electric telegraphs.

229. F. J. Jones, of Aldermanbury, Manufacturer. An improvement in shirt fronts.

230. H. Brecknell, of Bristol, Brass Founder, and J. Dyer, of the same place, Gentleman. Improvements in cocks and valves.

231. I. Woodcock, of Spitalfields, Frame Maker. Improvements in barometer and thermometer dials.

232. B. Spedding, of Birkenhead. Improvements in apparatus for generating and regulating gas, and for impregnating the same with volatile hydrocarbon fluids.

233. C. G. Kelvey, and W. Holland, of Birkenhead, Chronometer Makers. An improved escapement for chronometers and other time-keepers.

234. W. E. Newton, of Chancery-lane. An improvement in life preserving vests. A communication from A. T. Diano.

Dated January 27, 1859.

235. W. R. Alexander, of Glasgow, Merchant. Improvements in furnaces, and apparatus for the manufacture of sugar, and for the consumption or prevention of smoke.

236. I. Hammond, of Winchester, Gun Maker. Improvements in breech loading fire arms, and in cartridges to be used therewith.

237. O. Hussey, of Baltimore. Improvements in the construction of ships' blocks.

238. D. Graham, of Wapping, Millwright and Engineer. An improved method of driving centrifugal machines. A communication from T. Hanning.

239. J. Wells, of Keighley, Brass Founder, and W. Clough, of Sutton, near Keighley, Millwright. An improved coupling for railway carriages and analogous uses.

240. F. C. C. Paulsen and A. Alsing, of Linehouse. Improvements in preparing beverages usually called punch.

241. M. Fernandez, of Devonshire-sq., Bishopsgate, Merchant. Improvements in straw and hay cutters.

242. J. Kerr, of Southwark, Engineer. Improvements in the construction of revolving fire arms.

243. J. Mercer, of Boston, United States, Currier. Improvements in the process of currying leather. A communication from J. Armstrong.

244. W. Azer, of Rhorsburg, Columbia. Improvements in machinery for cleaning rice.

245. T. Hartshorne, of West Bromwich, Brassfounder. An improved metal to be used for making journey brasses for mills, rollers, forges, and all kinds of shafts and machinery, and also for shipping and for bearings for shafts and journey brasses in general.

246. E. Dixon, and H. Whittaker, of Preston, Mechanics. Improvements in apparatus used in weaving textile fabrics.

247. J. Meacham, of Birmingham. Improvements in pens and penholders.

248. H. D. P. Cunningham, of Bury, near Gosport, Esq., An improvement in the rig of ships or vessels.

249. H. Rawson, of Leicester. Improvements in machinery for preparing wool and other fibrous substances.

250. J. Buckingham, of Walworth Common, Civil Engineer, and G. Salt, of Saltaire, near Bradford, Manufacturer. Improvements in the construction and adaptation of drawing and other rollers employed in drawing and compressing fibres, which improved construction of rollers is also applicable in compressing fabrics.

251. E. T. Hughes, of Chancery-lane. Improvements in the manufacture of biscuits. A communication from Messrs. Pascal and Sirben.

252. G. F. Bradbury, of Oldham, and J. J. King, of Glasgow. Improvements in certain apparatus applicable to sewing machines.

253. W. Crowther, of Leeds, Manufacturing Chemist. Improvements in the manufacture of prussiates of potash or soda, and in recovering a useful material therefrom.

254. J. Gathercole, of Camberwell New-road, Gentleman. Improved machinery for manufacturing envelopes and paper bags.

Dated January 28, 1859.

255. I. Zacheroni, of Liverpool, Artist. An improved method of preventing the escape of smoke into the atmosphere, and in the construction of chimney pots or tops for curing smoking chimneys.

256. W. Robertson, of Manchester, Mechanician. A new apparatus for propelling boats on canals, rivers, and lakes of moderate depth.

257. G. Bartholomew, of Linlithgow, Tool Maker. Improvements in shoes for horses and other animals requiring such shoes, and in the means of attaching the same to the feet.

258. C. E. Amos, of Southwark, and J. Francis, of Bangor, Engineers. Improvements in water pressure engines, and their application to pumping machinery.

259. F. Prince, of New Bond-st., Gunmaker. A new breech-loading gun.

260. W. Yates, of Bromley, Middlesex, Engineer. Improvements in furnaces.

261. R. Griffiths, of Mornington-road. Improvements in regulating the pressure of steam in boilers, and in preventing the accumulation of deposit therein. Partly a communication from C. N. Copeland.

262. H. Watson, of Newcastle-on-Tyne. Improvements in the manufacture of Knotter plates, used in the manufacture of paper.

263. A. Barclay, of Kilmarnock, Engineer. Improvements in obtaining and distributing or applying electricity and magnetism.

Dated January 29, 1859.

264. L. Leisler, of Glasgow, Merchant. Improvements in extracting metallic copper from the pyrites residuum of vitriol works, and from other substances. A communication from Dr. Hasenclever.

265. J Lane, of West Bromwich, Machinist. New or improved machinery for the manufacture of screws, and for tapping nuts for screws.

266. J. MacKenzie, of St Martin's-le-grand, Gas Engineer. An improved method of operating ventilating valves, especially applicable to ventilating gas burners.

267. J. Marino, of Stockholm, Mechanician. An inodorous closet or commode.

268. G. Davies, of Serle-st., Lincoln's Inn. Improvements in apparatus applicable to measuring, regulating the pressure of, and consuming gas for illumination. A communication from J. M. Legris.

269. H. Grissell, of Eagle Wharf-road, Engineer. Improvements in machinery for moving ships or vessels on slips or inclined ways.

271. J. Meacham, of Birmingham. Improvements in apparatus for clasping and closing books, purses, reticules, and other similar articles, and for retaining and securing paper documents, letters, bills, and other memoranda.

Dated January, 31, 1859.

272. T. P. Smith, of Stanmore, Schoolmaster. An apparatus for guiding or directing the pen or pencil in writing or drawing.

274. J. Raywood, of Wentworth, Yorkshire, Engineer. Certain improvements in the constructton and method of working sewing machines.

276. J. Robertson, of Glasgow, Engineer. Improvements in details, by which motive force is transmitted in machinery.

278. J. P. Booth, of Cork, Feather Factor. Improvements in ventilating ships.

Dated February 1, 1859.

280. J. Grimond, of Manchester, Manufacturer. Improvements in the manufacture of hearth rugs.

282. J. Hosking, of Gateshead, and T. Cock, of Cleatormoor, near Whitehaven. Improvements in furnaces or fire places.

286. M. A. Walker, and R. Walker, of Birmingham, Percussion Cap Makers. Certain improvements in the manufacture of percussion-caps, and in the apparatus for effecting certain parts of the same.

288. T. P. Purssglove, of Battersea. Improvements in barometers.

292. C. Crockford, of Holywell, Flintshire, Smelter. A mode or method of producing metallic sulphates.

Digitized by Google

294. E. H. Bentall, of Heybridge, Essex, Ironfounder. Improvements applicable to machinery for grinding or pulverising various substances.

Dated February 2, 1859.

296. E. E. Allen, of Brompton-row, Engineer. Improvements in stereoscopic apparatuses.

298. R. Lancaster, of Orrell, near Wigan, Mining Engineer. An improved mode of ventilating coal and other mines.

300. J. R. Cooper, of Birmingham, Gun Maker. Improvements in breech-loading fire arms.

302. J. Buncher, of Birmingham, Brass Founder. Improvements in the manufacture of eyes or fastenings for stair rods.

304. J. Hirst, jun., of Saddleworth, York, Merchant, and J. Hollingworth, of the same place, Joiner. Improvements in the construction of power looms.

306. H. F. Kemp, and W. Skey, of Louth. An improved food for cattle.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

325. J. M. E. Masson, of Evreux, France, Gentleman. Improvements in apparatus to facilitate working under water. Dated Feb. 4, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 1365, 1367, 1374, 1385, 1390, 1394, 1419.
BOILERS AND THEIR FURNACES. *None.*
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1392.
SHIPS AND BOATS, including their fittings, 1366, 1386, 1387, 1388, 1389.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1362
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1363, 1364, 1371, 1383, 1400, 1402, 1405.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 1391, 1399.
LIGHTING, HEATING, AND VENTILATING, 1372, 1398, 1403.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1369, 1380, 1401, 1409.
METALS, including apparatus for their manufacture, 1368, 1376, 1410.
CHEMISTRY AND PHOTOGRAPHY, 1382, 1404.
ELECTRICAL APPARATUS, 1381.
WARFARE, 1373, 1321.
LETTER PRESS PRINTING &c. *None.*
MISCELLANEOUS, 1370, 1373, 1374, 1375, 1377, 1379, 1381, 1385, 1392, 1393, 1395, 1396, 1397, 1406, 1407, 1408.

1362. W. SAWNEY. *Improvements in apparatus applicable to screening, winnowing, and corn-dressing machines.* Dated June 16, 1858.

This invention consists:—1. In adapting to screens a set of toothed wheels to produce a quick tremulous motion of the screen. The wheels are mounted so as to admit of the screen resting upon them, and pieces of metal are inserted on the under side of the screen frame with inclined surfaces for the teeth of the wheels to work against successively, so as to raise the screen by the passing of the tooth over the inclined surface, and allow it to drop when the tooth has quitted the same. 2. In adapting to screens travelling brushes, for cleaning them while in use. The brushes are inserted in rollers, the axes of which are connected to a travelling endless chain on each side of the machine. The axes are mounted in grooved guides in the machine, or in such a way as to allow the brushes as they travel along to yield to the cross bars on the underside of the screen, by the roller in which they are inserted, being made to turn on coming into contact therewith. *Patent abandoned.*

1363. J. J. CREGEEN. *Improvements in the treatment of India and China grass, pine apple, hemp, flax, and other similar fibrous materials, and in the machinery or apparatus employed therein.* Dated June 16, 1858.

This invention relates to a mode of treating such vegetable fibres as India and China grass, pine apple, plantain, wild rhea, nilgerry nettle, fate, hemp, and flax, and other fibrous plants, whether green or after having been retted, in order that a silky or woolly material may be obtained, suitable for spinning. The patentee proposes to treat all resin-bound fibres (but especially pine apple and plantain, India and China grass, which cannot in this country be treated green from the soil) by steeping them in warm water, and afterwards washing and wringing them by pressing them between a drum, having an undulating surface, and small drums placed round it, or between two rollers having undulated surfaces. The central drum is heated in the wringing machines by passing the waste steam of the engine therein, or by gas-burners inside it, or otherwise, so as to wring the fibres, yarns, or fabrics nearly dry. The fibres are then bruised or crushed in a large perforated drum, having a slightly undulated surface, and fitted with ribs shaped like double or molar teeth, which ribs art in conjunction with others shaped like molar and canine teeth, and arranged alternately on the surfaces of a number of smaller and different sized drums surrounding the large one. When the fibres are dry a fan inside the main drum blows off the dust and resin. By making the surface of the main drum undulating, a beating action on the part of the smaller drums is obtained. This machinery can be driven either by hand, wind, water, or horse power, but the patentee prefers to connect the main drum with one of Hall's patent oscillating cylinder engines. The smaller drums surrounding the central drum are fitted in sliding brasses for readily disconnecting them from the teeth of the large drum. The brasses slide between anti-friction rollers. The fibres are next carried to steeping vats for the finishing process, previous to being spun, where they are steeped in oil of any kind, mixed with water and ammonia, or its carbonate, render the mixture saponaceous. The fibres are suspended in the vats by galvanised iron holders, and the hot water is poured over them into the vat through a perforated lid or cover. Steam pipes are used for keeping the mixture up to about 80° or 90° Fahr. If strength and length be preferred to fine quality of fibre, the patentee prefers immersing the fibres for about 12 hours in the saponaceous mixture, boiling water being added, and the whole then left to cool down under a closed cover. The fibres are now removed to a washing machine, which consists of a number of small fluted revolving rollers arranged round a central fluted and perforated drum. The lower rollers are partially immersed in a water tank, and a continuous jet of hot or cold water is directed into the perforated drum through its axle upon the fibres. The upper rollers squeeze out the dirty or resinous matter, and the attendant, after well washing the material, lifts it from the water tank, and passes it through the upper set of rollers only, whence it is removed, partially rung, to the dry wringing machines similar to that before referred to, which completes the process. These machines are applicable to the washing and wringing of yarns and piece goods. The same mode of treatment is equally applicable to green hemp and flax straws, and similar wood and resin-bound fibres, but in this case he first cleans out all the woody and resinous matter before washing and wringing and discharges, by means of hot water, all the dirt and resin. *Patent completed.*

1364. J. H. DICKSON. *Improvements in machinery or apparatus for scutching and hackling flax, hemp, and other similar fibrous materials.* Dated June 16, 1858.

This invention relates to apparatus for scutching and hackling flax, hemp, India and China grass, and other similar fibrous substances, and consists in the use of a peculiar combination of brushes, and scrapers, and openings, the scutching and hackling being effected in one machine. The fibres are presented to this machine by a pair of fluted nipping rollers in connection with a feeding drum, having a partial rotatory motion imparted to it by an internal segmental rack and a pinion. This drum is moved forward towards the cleaners and openers by a screw spindle, so that the fibres (which lay over a leather apron when under treatment) are accurately presented to the cleaning and opening apparatus. The openers which first operate on the fibres consist of blades or scrapers attached to rotatory arms at gradually diminishing distances from the centre, and are each fitted on their outer flat surfaces with projecting teeth, which incline back slightly, so as not to tear the fibres as they pass through them. The cleaners and brushers consist of brushes attached also to rotatory arms, and having spring knives placed within them for scraping or brushing off the resin and woody matter. The feeding drum is slowly turned round while the fibre is being operated upon, so as to present the whole length of fibre successively to the revolving cleaners and openers. The feeding apparatus can be easily adapted to the Irish scutching machines; or a round horizontal revolving table may be used with suitable holders and circular cleaners and openers of the description above referred to, these latter fitting the periphery of the horizontal table. *Patent completed.*

1365. J. C. HILL. *Improved apparatus for ascertaining and indicating the height of water in steam boilers.* Dated June 16, 1858.

The inventor connects a float (by a rod or cord, say) to a balance wheel, counterweighted on the opposite side, and fixed to a spindle which is mounted in bearings in the fork of a vertical steam pipe, and is perforated transversely like the spigot of a cock. When the hole in the spindle is brought opposite the steam pipe (which it is when the water either rises or falls excessively) steam passes to the whistles. A visible indicator may be also attached to the balance wheel. *Patent abandoned.*

1366. J. WESTWOOD. *Improvements in the construction of iron ships.* Dated June 16, 1858.

This invention was described at p. 47 of No. 3, for Jan. 14, 1859. *Patent abandoned.*

1367. G. DAVIES. *An improved equilibrium slide valve for steam engines.* (A communication.) Dated June 16, 1858.

The inventor's object is to obviate, in a great measure, the expense and delay of converting an ordinary slide valve into an equilibrium slide valve, by retaining the ordinary valve face, the steam induction and eduction passages, and the valve rod, so that only the valve itself and its casing require alteration. The form of the valve employed is

Digitized by Google

prismatic, and it is enclosed in a well-fitting case or cap, which serves as a guide to its longitudinal movement. This casing is A shaped, forming two sides of the prism, and the cylinder facing containing the steam ports forms its third side. In order to poise the middle of the valve, the steam is allowed to escape round the out-side of the valve by a groove passing round it. The steam passes to both ends of the box, either along an exterior passage, or through a longitudinal canal formed through the valve, in order that there may be the same pressure at each end of the valve. And in order further to counterbalance the outward pressure of the steam in the cylinder, the sides of the said canal are perforated, to admit steam between the upper sides of the valve and the casing or cap. In order to compensate for wear, one of the sides of the casing is recessed, and is fitted with a moveable plate, which is kept up to its work by wedges at the back, which are advanced when necessary, say by a screw. *Patent completed.*

1368. T. STEVEN. *Improvements in making moulds for casting.* Dated June 16, 1858.

Claims, 1, making external moulds—for casting pipes and other articles having two halves symmetrical about a plane through their respective axes, "and of which the halves require for their proper adjustment the coincidence of at least two pairs of counterpart points in their sectional surfaces"—by means of half patterns placed upon flat plates, as described. 2, making cores for pipes and similar moulds, by means of a pattern which forms a recess in one half of the core to receive the projecting part of the core bar partly imbedded in the other half of the core, and by shaping the said pattern and core bar respectively so as to form passages for air or vapour in the finished core. 3, the use, in moulds for casting axle bushes for cart wheels, of metal surfaces for chilling the ends of the bushes, as described. *Patent completed.*

1369. J. H. MARSDEN. *Certain improvements in the manufacture of hats.* Dated June 17, 1858.

This invention consists in forming the body of hats of straw, grass, chip, palm leaf, or other similar material, and the brim of felt, gossamer, or other suitable material, thus combining durability with lightness. *Patent abandoned.*

1370. F. WALTON. *A new or improved manufacture of japanned wares.* Dated June 17, 1858.

The inventor makes the body of iron as usual, applies a coating of black japan or other varnish, sprinkles on a powdered vegetable fibre—say, unsized paper pounded—hardens the japan, &c. (by stoving or otherwise), pastes sheets of unsized paper upon the flock (as in making papier maché), and finishes as is usual with japanned wares. *Patent abandoned.*

1371. J. HASLAM. *Improvements in looms for weaving, and also in shuttles and pickers connected therewith.* Dated June 17, 1858.

This invention consists, 1, of a longitudinal slide plate attached to the shuttle box, and so arranged that the back or top of the picker shall work in or against it, to steady the picker. 2, in cutting away part of the shuttle near the point, either at the top, bottom, or side, to form a shoulder against which the picker is to strike (instead of against the point as hertofore), so that a more solid blow is given, and the picker is not so soon worn out as when it strikes the metal point of the shuttle. The shape of the spring which acts upon the cop pin is also somewhat varied, to avoid the necessity of cutting away so much of the wood of the shuttle as usual. 3, in forming the pickers with a solid projection adapted to strike against the above shoulder of the shuttle. The picker may be of any suitable material, and the hole through which the guide-rod runs is to be fitted with a fast or loose bush of metal, glass, or earthenware. *Patent abandoned.*

1372. J. ALLARDICE and W. MILLER. *Improvements in gas-liers.* Dated June 17, 1858.

This invention was described at p. 47 of No. 3, for Jan. 14, 1859. *Patent abandoned.*

1373. A. DAWSON. *Improved apparatus for converting small coals or coal dust, or small coals and coke, or coal dust and coke, with the admixture of water or other materials, into artificial fuel.* Dated June 17, 1858.

Claims, 1. "The making of an endless trough such that the bass or bottom parts are so formed and connected to each other that, during the motion of the trough, these bottom parts form as they pass round the cylinder at each end of the chamber a smooth cylindrical surface, whereby the materials are capable of being scraped off the trough without exposure to the atmosphere. 2. The passing the endless trough with the materials into the heated chamber in such a manner that the top of the chamber forms the corner of the trough, and thus the materials are heated in the closed part of endless trough. 3. The general combination of the above described parts, which form the complete apparatus for manufacturing the blocks of fuel as above described." *Patent completed.*

1374. G. HALE. *Improved apparatus for obtaining motive power.* Dated June 17, 1858.

This relates to a mode of imparting motion and power to a horizontal shaft by means of a series of weighted levers, the weights of which shift so as to produce continuous motion. *Patent abandoned.*

1375. S. and D. TAYLOR. *Improvements in machinery or apparatus for putting machine straps or belts on to pulleys or drums, and for removing the same.* Dated June 17, 1858.

The inventor claims the use of a supporting surface for receiving the strap, capable of being removed from, and brought into coincidence with, the periphery of the drum; and also a siding apparatus described therewith for pushing forward the strap. *Patent completed.*

1376. C. CROCKFORD. *Improvements in the treatment of he ores of zinc, and in spelter making.* Dated June 17, 1858.

This invention consists, 1, in utilizing the sulphur contained in the ores of zinc. For this purpose the inventor so constructs a furnace for calcining the sulphuret of zinc that it may be introduced continuously in small quantity at one end of a chamber heated from below, and as it traverses the said chamber be acted on by a current of heated air, whereby the sulphur is converted into sulphurous acid which passes away in a continuous stream, and may be used for making sulphuric acid, or for any other purpose. 2, in a mode of treating carbonate of zinc for obtaining carbonic acid, &c. The carbonate is treated in a vessel with sulphuric or muriatic acid, and carbonic acid is given off. The sulphate or muriate of zinc which is also formed may also be collected and used. 3, in a mode of obtaining products from the zinc vapours passing through the flues of the retort furnaces used in spelter making. He injects a stream of muriatic gas and a jet of steam into such flues, whereby the zinc fumes are converted into muriate of zinc, which may be condensed and collected. Or muriatic or other acid may be thrown into the flues in showers, and zinc salt be collected. 4, in treating the residue left in the retorts after the reduction is completed. This residue consists of about equal proportions of oxide of iron and oxide of zinc, and this being mixed with a small quantity of clay, or lime, or both, is submitted to a blast in a cupola or blast furnace the vent of which is conducted into a cistern of water. The iron is thus reduced, and may be drawn off at the tap-hole. The oxide of zinc is carried into and deposited in the water, whence it is collected. *Patent abandoned.*

1377. W. BLIZZARD. *Improvements in india-rubber, gutta percha, and drying and other oils.* Dated June 18, 1858.

This invention is for manufacturing from india-rubber and gutta percha a transparent solution for indurating textile fabrics, papers, woods, marble, stone, cements, and all other porous materials, to render them waterproof. The agents used are sometimes plain water, or water with seeds dissolved therein, to which is sometimes added a little quick lime. These are sometimes submitted to different degrees of temperature. *Patent abandoned.*

1378. J. SHAW. *Improvements in fire-arms.* Dated June 18, 1858.

The inventor uses a safety bolt, which locks the hammer, except when pressure is applied to the end of the stock, as when it is pressed against the shoulder previous to firing. *Patent abandoned.*

379. R. S. NEWALL. *Improvements in the manufacture of cords, ropes, and cables.* Dated June 18, 1858.

This consists in laying yarns into a strand so as to retain the twist given to them in the spinning. A number of such strands are then laid into a cord or rope without altering the twist of the strands. The yarns or strands may also be laid round a core, which core may be either of yarns, or an insulated wire, so as to form, in the latter case, a submarine electric cable. *Patent abandoned.*

1380. W. SPENCE. *Improvements in clogs, shoes, or supports for the feet.* (A communication.) Dated June 18, 1858.

Here the sole is of thin metal, hinged to give flexibility. At the hinder end is a shell of leather or metal to receive the heel, and at the fore part is a toe piece of leather or metal. A blade or skate, hinged like the sole, is rivetted to the shoe. On each side of the sole at the hinder part is a lug in which is inserted a stud for holding each end of a strap for confining the sole to the foot. The strap is fitted so as to be adapted to the height of the instep of the foot. *Patent abandoned.*

1381. P. B. E. MARTIN. *Improvements in obtaining electro-motive power.* Dated June 18, 1858.

This invention consists in obtaining motive power by means of the expansion or dilatation produced in a mixture of combustible gas and air, on the same being put into a state of combustion by the electric spark, either with or without the aid of steam generated by the combustion of the said gas and air, or of steam otherwise generated. The heated dilating gasses may be applied to heat a steam boiler, or the gasses and vapour combined may be employed in the same manner as ordinary steam to produce motion by direct re-action upon fluids for propelling vessels or otherwise; or they may be used for projecting projectiles, and for any other purposes to which such sources of power may be applicable. *Patent completed.*

1382. F. G. SPILSBURY. *Making tungstic acid and certain of its salts, and for using the same to decolour acetic acid and its compounds.* Dated June 19, 1858.

The inventor mixes with wolfram—or with ores containing wolfram—bisulphate of soda or potash, or a mixture of sulphate, or muriate of soda or potash, and sulphuric acid, and subjects the whole to a red heat, "until the wolfram is separated into tungstic acid, and sulphate of iron, and magnesia." He decolours acetic acid by boiling a solution of coloured acetate of lime or lead with tungstic acid, whereby the colouring matter is precipitated with the tungstate of lime or lead, and acetic acid is left in solution. He then combines the acetic acid with oxide of lead or barytes, and precipitates with tungstate of soda, whereby he obtains tungstate of lead or barytes, and pure acetate of soda. He prepares tungstate of soda or potash by boiling wolfram, or tin ores containing wolfram, under pressure in solutions of caustic soda or potash. He also decolours acetate of lime or lead by adding tungstate of soda to its solution. Lastly, he obtains tungstate of lead, barytes, strontian or lime, by boiling their respective sulphates or carbonates (with or without pressure) in a solution of tunstate of soda or potash; or by heating in a furnace either of the above sulphates or carbonates, previously ground, with dry tunstate of soda or potash, or dry tungstic acid. *Patent abandoned.*

1383. S. HEWITT. *An improved application of printed designs to cotton and other fabrics, and for improvements in the treatment during the processes of printing and finishing such fabrics.* Dated June 19, 1858.

This consists in printing the design on one or both sides of a woven fabric, having a pattern thrown up in the weaving on the plain side; and in then dyeing such printed fabrics in fast colours. Also, in certain treatment during the printing and finishing. The object of these improvements is to produce fabrics on which the design is printed in imitation of fabrics with woven designs. *Patent completed.*

1384. Application was made for the provisional protection of an invention bearing this number, but the protection was refused by the law officer. *Patent abandoned.*

1385. J. BRADSHAW. *Certain improvements in apparatus for obtaining and producing motive power.* Dated June 19, 1858.

Here a vertical shaft carries a horizontal disc furnished with radial iron bars which are permanently magnetised, and the poles of which are alternated. Above these bars, and just clear of them, is arranged a series of electro-magnetic coils, connected with a battery. The magnets of these coils impart motion to the bars (and therefore to the disc and shaft) both by attraction and repulsion, as is well understood. *Patent abandoned.*

1386. R. and T. WINANS. *A new and useful improvement in the form of the hulls of steam vessels.* Dated June 19, 1858.

The inventor forms the hulls of vessels with all their transverse sections, circles, and all their longitudinal axial sections composed of two arcs of a circle, their object being "to diminish the variation of resistance to winds and waves which causes a vessel to roll;" and "to diminish those resistances which prevent the vessel when 'careened' or inclined to one side from 'righting.'" *Patent completed.*

1387. R. and T. WINANS. *A new and improved steam vessel.* Dated June 19, 1858.

This invention, which relates particularly to ocean steamers, and has for its object "the attainment of a more constant rate of progression under different conditions of weather than is attainable in vessels of the ordinary form," consists in the combination of a hull circular in all its sections and tapering towards both ends, with a transverse vertical propeller occupying a space between the two portoins of the vessel, which are secured together by a framing or "sleeve" extending over the propeller. The invention also comprises the "sleeve" and a series of ribs for connecting the ends of this sleeve respectively with the adjacent ends of the two parts of the vessel, steadying the vessel like a keel, and with the "sleeve" directing the water to and from the blades of the propeller. And it further consists of means for affording ingress to, and egress from, each of the two parts of the vessel, a communication between them, and a means of ventilating them. *Patent completed.*

1388. R. and T. WINANS. *A new and useful improvement in ocean steamers.* Dated June 19, 1858.

This invention consists in the combination of a vertical transvere trunk within the hull of a vessel, with a large screw propeller, the blades of which project beyond the hull. *Patent completed.*

1389. R. and T. WINANS. *A new and useful improvement in the mode of combining the engines and propeller shafts of steam vessels.* Dated June 19, 1858.

This invention consists in the combination of two engines, or two sets of engines, with an intermediate vertical transverse propelling wheel, to the shaft of which the engines are connected. *Patent completed.*

1390. R. HALLDON. *Certain improvements connected with engines worked by steam or atmospheric power.* Dated June 19, 1858.

This invention consists in increasing the power of engines by interposing lazy-tong levers between the piston rod and the crank. *Patent abandoned.*

1391. H. BECU. *Improvements in the manufacture of laths, and in fixing and nailing the same.* Dated June 19, 1858.

The inventor cuts parallel slots through long pieces of wood, each thick enough to be slit up into several laths, leaving solid wood between the slots to come against the joists or timbers to which they are to be nailed. He then slits these pieces into laths of a proper thickness, such laths are nailed to the joists or timbers through their solid parts. *Patent completed.*

1392. Sir J. C. ANDERSON, Bart. *Improvements in locomotion, parts of which are applicable for other purposes.* Dated June 21, 1858.

1. On a concrete and stone foundation the inventor places a pavement of stone, bricks, or wood, or timber plated with iron, and on this a tramway. Between the rails of his tramway he lays down a T rail, and to the locomotive he connects horizontal wheels running under the head of this T rail, which wheels guide the train round curves, and prevent its leaving the line. 2. When a train has to ascend an incline, he connects to it one end of a rope which passes round a pulley at the top of the hill, and has attached to its other end a loaded carriage, which counterbalances the weight of the train, and leaves the engine its usual amount of duty only. 3. He makes the flanges of his wheels partly conical (like ordinary railway wheel flanges) and partly cylindrical; the conical part runs on the rails, and the cylindrical part runs when desired on common roads. 4. For ascending inclines, he builds a small inner wheel on the inside of each of the outer wheels, and lays down a raised track for such small wheel to run on, taking the weight of the train. He thus loses speed but gains power. The small wheels and their track may be cogged if necessary. 5. To the fore wheels he connects steering apparatus to run the train off the rails when necessary. 6. To increase friction he causes the carriage wheels to run on the concave surfaces of larger wheels, and provides for causing "the weight of each carriage to become a propelling power." 7. He has an arrangement for drawing a vertical shaft by means of a locomotive attached to a beam projecting horizontally from the said shaft, and running on a circular cogged tram-road, in such manner that "gravitation" will become a propelling power, which may be increased to any extent. 8. By forcing air by a fan through a small pipe contained within a large one, the latter being open at both ends, and leading from the front of the locomotive into the ash-pit, a strong blast is to be drawn through the large outer pipe into the ash-pit. *Patent abandoned.*

Digitized by Google

1393. H. H. HENSON. *Preserving or waterproofing ropes, strands, cordage, cables, and other similar articles.* Dated June 21, 1858.

The inventor coats the ropes, &c., with wax, resin, glue, shellac, India rubber, gutta percha, vulcanite, marine glue, or oil, paints, pitch, tar, varnish, or japan, or solutions of any of these in naptha, turpentine, or other solvent, or mixtures of any two or more of them, and he then passes the ropes, &c., if required, through grooved rollers, or finishes in the ordinary manner. Or he saturates the fibre, the rope, &c., with any of the above-mentioned materials, or with tallow, mixed or unmixed with arsenic, or with tannin, with or without subsequent subjection to fatty matter, or to a mixture of water, sulphate, or silicate of potash, and alumina, and compounds of lead, or to a saponaceous matter, and subjects them to the action of silicate solutions; and he effects their saturation by immersion, or by pressure, or exhaustion, with suitable vessels and chambers. Or he passes the rope or other article, when complete, through a mixture of asphalte, vulcanite, marine glue, gutta percha, or other similar material, and then passes it through rollers grooved to give it any desired form, and dusts it with siliceous compounds, vegetable, or animal dust, or powder, or covers it with hemp. Or he covers the rope, or each strand forming the rope, &c., with a covering of pure or mineralised caoutchouc. *Patent completed.*

1394. R. A. BROOMAN. *Improvements in steam cocks.* (A communication.) Dated June 21, 1858.

This invention consists in constructing steam cocks, so that the plugs shall not be liable to stick or jam, and that steam may not pass off through the casing in which the plugs are fitted. The plugs are made in brass, hollow and conical, and have a small aperture open to the steam when passage through the cocks is shut off, which aperture leads into a space between the solid top of the plug and a cap or shield formed on the lower part of the key for turning the plug. The cap or shield is kept from rising by a cover bolted on to the body of the cock; in this cover there is a stuffing-box, through which the shaft of the key works. A screw works through a stuffing-box bolted to the bottom of the body of the cock, which can be brought to bear on the bottom of the plug, and, if necessary, ease it up off its bearings. The body of the cock may, for economy's sake, be made of iron and the plug of brass, or the whole may be of brass, or gun or other suitable metal. *Patent abandoned.*

1395. R. A. BROOMAN. *Improvements in treating wood to preserve and colour it, and in apparatuses to be employed therein.* (A communication.) Dated June 21, 1858.

These improvements consist, 1, in extracting the air from the cells of the wood to be treated in a close vessel; in then admitting of steam, which will enter, heat, and expand the cells of the wood; in then withdrawing the steam, and finally in forcing, preserving, or colouring fluids into the vessel, and into the expanded cells of the wood. The preserving fluids employed are the metallic salts in solution, principally the sulphate of copper, with which is sometimes combined sea salt, or sulphate of soda, or both. The colouring fluids employed may be of any suitable kind. They consist 2, in the employment for the purpose described of a cylindrical, or other vessel, with a moveable end or cover attached to it by hooks or screws, with a ring of india rubber between the two, with which are also combined a pump for exhausting it, a boiler for supplying it with steam, and reservoirs for supplying it with preserving and colouring fluids, together with suitable pipes, taps, valves, pressure guages, &c. They consist, 3, in treating telegraph posts, and other lengths of wood, by smoothing one of the ends of each, and placing upon the smoothed end a ring of india rubber, and against that a disc or discs of wood, or other material, so as to form a closed chamber within the india-rubber ring, and by forcing a preserving fluid into this chamber under great pressure, until the fluid is caused to penetrate and pass through the timber, saturating the same. The discs are temporarily secured to the ends of the posts by bolts or screws, or otherwise, and have a hole in the centre to admit the fluid. By connecting a number of flexible cubes to one feed-pipe, and leading such flexible tube to a post, any number of posts may be treated simultaneously. By means of this invention a continuous current of steam may be passed through or into the wood under treatment, and withdrawn by the action of the condenser, so that it will not condense in the pores of the wood. The employment of a separate condenser in communication with the vessel containing the wood, also prevents that cooling down of the vessel which results from the system of direct condensation. If the preserving and colouring solutions be introduced hot, they will tend to still further distend the pores of the wood which the steam has already distended, and thus to impregnate the wood more effectually than otherwise. *Patent completed.*

1396. J. LAWDER. *A method of supporting or carrying knapsacks, packs, and other weights on the back.* Dated June 21, 1858.

This invention consists in attaching two straps to the fore part of the body of the trousers, one on each side, the two to be united, say by a buckle, when on the wearer. Through an aperture in each side of the coat the inventor connects this strap by hooks to the waist belt, and brings straps attached to the knapsack or weight to be carried over the shoulders, one on each side, and connects these straps to the waist belt; or, if preferred, directly to the straps on the trousers. The bottom of the knapsack, or weight to be carried, is furnished with a steadying strap, which is connected at back to the waist belt. *Patent abandoned.*

1397. J. CROSSLEY. *Improvements in machinery for grinding, smoothing, and polishing glass.* Dated June 21, 1858.

In carrying out this invention a vertical crank shaft or axis communicates rotatory motion by two connecting bars or rods to two other upright cranked axes, and these axes are connected by a third connecting bar or rod longer than the other two. Each bar has a bearing for the upright axis of one runner, the longer one giving motion to two runners. The glass to be ground, &c., is so fixed on a horizontal table, that the rubbers will each be caused to be moved on its surface by the connecting bars or rods, the axis of each rubber describing a like circle to the three cranks before mentioned, the rubbers being each also capable of rotating with its own axis, and the rubbers are so arranged that in their action they overlap each other's extent of action and the edges of the glass. The number of cranks, connecting bars, &c., may be varied. *Patent completed.*

1398. W. C. WILKINS. *Improvements in lamps.* Dated June 21, 1858.

This invention will be described in a future number. *Patent completed.*

1399. W. THRIFT and A. HIGH. *Improvements in house water-closets.* Dated June 21, 1858.

These improvements relate to the application of certain gear for actuating the water-supply valve, and the tumbling basin or soil pan, the motion being communicated thereto by the raising and falling of the seat of the closet by the weight of the person sitting on and removing therefrom. The inventor employs two basins, one in connection with the seat, the other with one arm on the axis of the tumbling pan, and with the valve to admit the water. When the seat is depressed, a weighted catch suspended from the end of the first lever (that connected with the seat) swings over a stop on the pan lever. When the sitter rises, the catch descends and moves the valve lever, but again releases itself before reaching its lowest position. Certain contrivances for causing the valve to shut slowly are also used. *Patent abandoned.*

1400. W. E. NEWTON. *An improved method of effecting the separation of the fibres of wood for the manufacture of paper therefrom, which is also applicable to the separation of the fibres of flax or other substances for the manufacture of textile fabrics, and also to the separation of other substances for similar or other purposes.* (A communication.)

This invention consists in subjecting wood, &c., in a strong cylinder to the action of steam, air, gas, hot water, or other fluid under a high pressure, for the purpose of charging its small tubes (in which the sap circulates), as well as the spaces between them, and in then suddenly projecting the wood from the cylinder into the atmosphere, or into a partial vacuum, the expansive force bursting the tubes, and separating the fibres. *Patent completed.*

1401. A. V. NEWTON. *An improvement in the manufacture of spoons and forks.* (A communication.) Dated June 21, 1858.

The inventor uses malleable cast iron instead of the copper or brass used in electro-plated ware. *Patent abandoned.*

1402. W. E. NEWTON. *Improvements in the process and machinery for obtaining from waste and refuse felted fabrics of wool, fur, or other materials, fibres in a suitable condition for being worked into felt and other fabrics.* (A communication.) Dated June 21, 1858.

This consists, 1, in subjecting the waste felts to the action of steam preparatory to, and in combination with, the action of machinery for picking and tearing the fibres from each other, the steam having the effect of loosening that interlocking of the fibres which is produced in the original felting action. 2. In tearing apart waste felts by combining a steaming apparatus with a picker, so that the felts may be thoroughly steamed before and during the picking operation. 3. In acting on fibres of fur or wool obtained from the disintegration of waste felts, so as to separate the fibres from impurities, and from lumps of felt which have not been thoroughly disintegrated, by so combining an inclined deflecting surface with a rotating picker or brush, that as the stock to be separated is separated from the feed rollers by the rapidly rotating picker or brush, and thrown violently against the inclined surface of the deflector, the separate fibres will be carried up by the current of air induced by the rotation of the picker, and discharged over the upper edge of the deflector, whilst the impurities and the lumps of felt will roll down the deflector, and be discharged at the bottom. *Patent completed.*

1403. G. R. SCRIVEN. *An improved apparatus for ventilating, and for circulating, moving, or otherwise acting upon air or other fluids.* Dated June 21, 1858.

This invention consists in the combination of a cylindrical drum of uniform diameter revolving on journals (by preference horizontal), one of which is tubular from the end of the drum, with a spiral pipe or passage coiled around or within the drum, open at one end, so as to freely admit air and water or other fluids in contact with one outer surface of the drum, with a free passage through such coils into the tubular journal, "into which the other end of one pipe or coiled passage enters water and air-tight through the said tubular journal into a vertical or other stationary pipe attached water and air-tight to it by the usual method of packing, and in which it turns out of one side pipe at its opposite end. A reservoir enclosing the clyndrical drum, and in which it revolves partially immersed in water or other fluid, provided with air and water feed-pipes, and a float valve to regulate the quantity of water therein. A reservoir of water and air-tight, into which the coiled pipe communicates through the tubular journal and the air and water discharge pipe, when necessary the discharge water pipe conducting back to the reservoir, and an air discharge pipe for the escape of air. Lastly a contrivance to receive the water or other fluid at its maximum point of elevation in the vertical pipe, and transfer it back to the cylindrical drum, there to act to one extent of its gravity as a motor, or driving power, any deficiency thereof being supplied by any known motive power, or by hand labour." *Patent abandoned.*

1404. H. DEACON. *Improvements in purifying alkaline lees.* Dated June 21, 1858.

This relates to processes for purifying the liquors or alkaline lees containing alkaline sulphides obtained in the manufacture of alkalines, such as soda and potash, or carbonates thereof. These processes consist, 1. In adding hydrated protoxide of iron, or hydrated peroxide, or hydrated magnetic oxide of iron, to such lees at any convenient temperature not exceeding 130° Fahr. 2. In separating at any lower temperature not exceeding 130° Fahr., the precipitate produced in and upon such lees, by the reaction at a higher temperature of any salt of iron, except its sulphides, or of any oxide of iron when added thereto. 3. In adding any salt of iron, or oxide of iron, to such lees in a state of concentration, at or near their boiling points, and in subsequently diluting them and separating the precipitate. 4. In exposing the said lees after any salt or oxide of iron, manganese, or zinc bars have been applied thereto, to the action of atmospheric air and agitation 5. In the application of temperatures between 130° Fahr. to such lees when containing any ferro or ferri-cyanides. 6. In the admixture of caustic lime or magnesia to the precipitate produced by a metallic salt or oxide reacting on such lees, for the purpose of retarding the oxidation of the precipitate during the separation of the alkaline lees therefrom. 7. In roasting such precipitate, when not mixed with lime or magnesia, with an alkaline chloride, with the view of producing a corresponding alkaline sulphate, so as to utilise the precipitate. *Patent completed.*

1405. M. MAYALL and G. JACKSON. *Improvements in machinery or apparatus for spinning cotton and other fibrous substances.* Dated June 22, 1858.

This relates to the self-acting mule, and consists in substituting a friction coupling for the ordinary clutch-box gearing hitherto used on the vertical shaft, which causes the drawing up or running in of the mule carriage. This coupling may be adjusted to convey any required amount of driving power, and to stop the carriage on the slightest obstruction occurring. *Patent abandoned.*

1406. G. SCHAUB. *Improvements in the manufacture of door plates, sign-boards, and other surfaces, having inscriptions, designs, or ornaments thereon, and in the manufacture of detached letters, designs, and ornaments to be affixed to walls and sign-boards or used for other like purposes.* Dated June 22, 1858.

Claims: 1. Manufacturing the above-named articles by electro-deposition, either upon a compound matrix, built up of separate matrices, or upon a matrix obtained by taking a mould from a pattern surface, built up of several pieces, or made of separate pieces attached to a plain surface. 2. Manufacturing such articles by casting an easily fixed metal, or alloy, or plaster of Paris, or other cement upon the backs of letters or ornaments placed face downwards in the proper order upon a plane surface. 3. Manufacturing such articles by electro-deposition effected on matrices, portions of which are stopped out by varnish, gutta percha, or other non-conductor of electricity, the said matrices being obtained by electro-deposition from plates engraved with lines serving as guides in applying the varnish, or the said matrices being produced by transferring designs obtained from lithographic stones, &c. 4. Making inscribed or ornamented plates to be used for printing from, or otherwise, by taking an electro-deposit from a metal plate on which a design printed from any convenient surface has been transferred, the deposition being continued until the reduced copper or other metal has spread over and covered the lines of the transfer, and thus produced a continuous plate, having a sunken design on it. *Patent completed.*

1407. W. and J. GALLOWAY. *Improvements in machinery for cutting, bruising, chipping, and rasping, and otherwise treating or preparing dye woods and roots or other vegetable substances.* Dated June 22, 1858.

The first part of this invention is not described apart from the patentee's drawings. For cutting, chipping, or rasping dye woods they employ a disc, a cylinder, or an angular rasp barrel, as described in the specification of their previous patent, dated May 14, 1856. They fix in such disc, cylinder, or barrel, plain sharp knives, in addition to, and alternating with the ordinary grooved or serrated knives, so that the wood is reduced to a finer state than grooved knives alone will reduce it. The machine may be used for reducing dry roots. *Patent completed.*

1408. J. PYM. *Improvements in machinery for felling trees.* Dated June 22, 1858.

Instead of using the axe or cross-cut saw in the ordinary way, the inventor bores with augurs (mounted on a frame, and made to work by toothed gear) one or more holes in a line through the butt or lower part of a tree; and, with a saw or saws, he saws the tree nearly in two, leaving as much wood uncut on each side of the tree as will prevent its settling down and pinching the saws. He then withdraws the saws and cuts with an axe or other instrument one or both sides of the tree until it falls. The augers and saws are each placed in a frame attached to a carriage with gearing to work the augers and saws, which gearing he sets in motion by manual or other power. Drills may be used in the place of augers, but he prefers the latter. *Patent abandoned.*

1409. J. A. RAINE. *Improvements in collapsible framework for bedsteads, sofas, and other like articles of furniture.* Dated June 22, 1858.

This invention consists in applying a system of cross levers, similar to lazy tongs, so that by a single set of them on each side of the bedstead or other frame it can be distended or collapsed and fixed at any intermediate length. *Patent completed.*

1410. W. E. KENWORTHY. *Improvements in the manufacture of steel.* Dated June 22, 1858.

This invention consists in the use of woollen rags, or woollen waste, as a substitute for charcoal in the manufacture of steel. *Patent abandoned.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, FEBRUARY 25, 1859.

THE ELEVATION OF MR. ARMSTRONG.

HONOURS and emoluments have descended upon the inventor of the new rifled cannon. On Wednesday last, Mr. WILLIAM GEORGE ARMSTRONG, of the Elswick Works, Newcastle-upon-Tyne, was presented to the Queen to receive the honour of Knighthood, and on his appointment as Engineer to the War Department for Rifled Ordnance. Mr. ARMSTRONG was presented by General PEEL. All praise to the Government that knows so well how to value and reward the ability of a practical hard-working Engineer! Twice during their short term of office have Lord DERBY's Government dignified men whose sole claims to honour are to be found in their scientific skill, their courageous industry, and their undoubted excellence of character. Sir CHARLES BRIGHT, who though young in years, is old in experience and in good repute, and whose anxious and unremitting exertions during the memorable expedition in the *Agamemnon* will never be forgotten by those present, was the first engineer whose talents and zeal received the homage of the Government now in power. And now like homage is paid by the same Government to another man who richly deserves the honours accorded to him. For, it should be recollected, Mr. ARMSTRONG's services in connection with gunnery did not commence either this year or last. For a long period he has applied himself to ordnance improvement, and has throughout displayed an aptitude for the work that has been very remarkable. Most cordially we congratulate Sir WILLIAM ARMSTRONG on his promotion, and on his appointment also; and with equal cordiality we recognise the spontaneity and grace with which Ministers have acted in the matter. In honouring him, General PEEL and his colleagues have brought honour to themselves.

There will not, doubtless, be wanting those who will see in this act of the Government little beyond a bid for popular favour. But there is more in it. There is this, at least, viz., a recognition of the dignity which belongs to inventors, and to practical men generally. And beside this, there is in it an open declaration before the world that the self-reliant and self-sustaining spirit of this country is strong in us yet. In the midst of our own peaceful manufacturing classes we have men who can turn, if need be, to the arts of war, and carry them forward far beyond the point to which the great military nations of the continent can of themselves attain. And, still further, there will result from the promotion of Sir WILLIAM ARMSTRONG a positive accession to our national prestige. The nations that stood in just awe of us yesterday, will stand in greater awe of us to-day, when they learn that an English engineer has put into our hands a weapon of such decided merit that Ministers of the Crown have sought his services, and the Queen herself has done him public honour.

The only drawback to our gratification on occasions like this is the thought of those who have deserved like favours, but deserved in vain. Who can doubt, for example, that, if the stream of Ministerial and Royal favour flowed with uniform freedom, the name of LANCASTER would at this moment be unhonoured? It may serve the purposes of some to speak lightly of the merits of the great Lancaster guns, and to dwell upon the defects which bad materials and bad manufacture produced. But everyone who remembers the influence which the very name of those weapons exerted during the late war, and who knows the real merits of the oval bore cannon, will act otherwise. Apart from ordnance altogether, Mr. LANCASTER has done so much for the nation—in producing those admirable rifles which are the desire of the Service—that no name deserves to stand before his. A wise Government would see to this.

But these reflections must not lead us to think lightly of the justice which *is* done. We have all along felt that the time must come when honour would be cheerfully shown to the genius of science, in both its theoretical and practical embodiments. That time seems now to be fast approaching, and the Government of Lord DERBY may justly feel proud of the part they are taking in hastening it.

THE TONNAGE LAWS.

"SOME are born great, some achieve greatness, and some have greatness thrust upon them." Mr. ATHERTON and his co-mates in the Tonnage Law agitation may justly lay claim to be inscribed in the category of those who "achieve greatness." Perseverance which, when boys, we learnt was the surest road to success, cannot, at all events, be denied them. The inauguration of the movement by the reading of a paper at the Society of Arts in January, 1856, will be in the recollection of our readers—followed by the appointment of a committee to report on the subject by the British Association, under the chairmanship of Lord HARDWICKE, the same year. On that committee all the practical ship-builders, except Mr. JOHN SCOTT RUSSELL, refused to serve, and it will be remembered that even under these circumstances Mr. ATHERTON was unable to obtain a report in his sense. Well, at the Dublin meeting of 1857, another committee was appointed whose nominal duty was to inquire into "shipping statistics," from which much of the former adverse element was eliminated, and which was, unfortunately for Mr. ATHERTON, opened by an act of repudiation on the part of Admiral MOORSOM, and Messrs. SCOTT RUSSELL and M'CONNELL, leaving Mr. FAIRBAIRN the only independent representative of public interests in this body. It is, we should think, no exaggeration to say that the report presented at the last meeting of the Association was the sole production of Mr. ATHERTON, and his *fidus achates*, Mr. ANDREW HENDERSON. This report has already appeared in our columns. As might have been expected, the attempt to pry into the private concerns of the shipping classes has proved a decided failure, although Mr. ATHERTON says it has not been "wholly fruitless." A stronger condemnation of the movement, and of the just suspicions of the shipowners, could not be found than in the candid but surely unwise admission in the report, that "ship-owners, ship-builders, and marine-engine manufacturers have been generally reluctant to communicate particulars whereby the dynamic merits of ships may be numerically classed and compared, the results of which classification and comparison *might, if promulgated, affect the commercial value of their property, and the relative professional reputation of constructors.*" What right has a committee of the British Association to take upon itself functions which might result in the private injury of commercial and engineering firms! The adaptation of steam to shipping purposes is necessarily progressive; fresh discoveries are made every year; and a firm which stood highest one year might, by accidental circumstances, be outbid the next. But upon the whole the progress has been satisfactory and healthy. Mr. ATHERTON's committee, had they been successful in their attempts, would have achieved the grand triumph of ruining all the ship-builders and engine-makers, whatever had been their previous merits, for the benefit of the individual firm which happened, in the tentative process which has been employed by all, to have made the last most successful hit. In whose interest is such a result desirable? Not of the commercial classes, as Mr. ATHERTON confesses; not of the public—for the undue establishment of a monopoly which this scheme must have resulted in, would soon have been felt most prejudicial to the public interest. It surely never can be to the public advantage that all the shipping and engines which do not come up to the latest improvements of 1859, however meritorious in their day, should be broken up as so much old wood and iron, and the commercial navy of the country be required to undergo a "complete re-construction" with every fresh discovery. The question is,—Do ship-owners and ship-builders manifest an anxiety, in the additions they are continually making to the commercial navy, to profit by the most approved methods of construction and engine adaptation? It is manifestly their interest to do this in order to insure success in the vast competition they have to encounter; and we believe they are fairly successful. The construction and adaptation to steam purposes of the commercial navy has shown a steady and healthy progress, which it would be most unwise to impede by any unhealthy attempt to accelerate it.

The committee succeeded, it seems, in obtaining a full account of the *Bremen*, of 3,340 tons—of her lines, her engines, and her performance. And nothing can illustrate more strongly the mischievous effects of the proposed action of the committee than this report. We give her builders full credit for their readiness to afford the information requested. But what is the consequence? The main ingredient of the report is a laudation of this ship; and by the adoption of this report the British Association for the Advancement of Science have really converted themselves into advertisers of the *Bremen* and all concerned in her construction, her engines, and her navigation. A dignified and honourable situation for this august body!

We regret to see the name of Mr. FAIRBAIRN appended to this report. That gentleman has experienced in his own person the advantages of public competition and individual enterprise to such an extent, that we are astonished to see him lending his great authority to a movement which, if successful, would so shackle the shipping interest as to reduce them to a state of prostration, or rather paralysis, from which they could with difficulty recover. In the name and for the interests of the public let us by all means have the most improved ships and engine adaptation. But do not let us, to reach this end, ruin the existing shipping interest.

Mr. ATHERTON'S unprecedented success has induced him to apply for, and the British Association to grant, a new committee, compared with which all former committees sink into the "cold shade." In this way has he now achieved greatness. Three live lords—yatch club *dilletantes*—and an ex-first Lord of the Admiralty (too old a bird, we think, to be caught by chaff of any kind), are now united to prosecute this precious movement, we presume in behalf of the shipping interests, of which we see no representative but Mr. SCOTT RUSSELL—who has before "repudiated." Surely the unanimous disapproval of ship-owners, ship-builders, and marine-engine-makers might open the eyes of any one less determined than Mr. ATHERTON to the real nature of the course on which he has entered!

THE CIVIL SERVICE.

As the Civil Service Superannuation Bill is at length passing through its various stages, and taking its place on the Statute Book of the State, it becomes the duty of all guardians of the public interests to take especial note of the spirit in which the Government intend to carry out its enactments. The age-limitation clause of the new Bill is certainly one of its most important points, for it will inevitably place in the hands of the Ministry a great amount of patronage. It may safely be asserted that there is not one establishment—be it Dockyard, Arsenal, Mint, or merely official Institution—in which vacancies will not naturally result from the action of the Derbyite Civil Service Bill. In all these places it has been the practice for veterans—who in their day may, doubtless, have been of great value to the country—to retain possession of their posts and their pay until long after the capacity for either doing the duties of the one or enjoying rationally the advantages of the other has passed away. And antiquated gentlemen who have not the sense of justice sufficiently strong within them to know that in clinging to salaries which others earn for them they are guilty of dishonesty, require to be told that such is the fact. In every Government establishment throughout the kingdom, we say, instances of this kind exist. On fair retiring allowances these impediments to improvement will now be removed, and it becomes a question of momentous consequence to the *tax-payers* of the nation as to who shall fill their situations.

It will not be submitted to at this time of day that political influence, official intrigue, favouritism, or any other corrupt power shall have effect in the appointments and promotions which must follow the dislodgment of these ancients. There is fortunately at this hour a Vigilance Committee constantly sitting and keeping watch and ward over the public good. That Vigilance Committee does not, however, like its Californian prototype, act upon the rough principles of Lynch, but rather upon the deliberate results of truthful deduction. We need not say that that Committee is composed of the representatives of the Free Press of England. With such an institution keeping it in check, sifting its motives, and examining its doings with argus eyes, it will not be possible for Ministers, be they whom they may, to perpetrate injustice to any extent in the carrying out of the great work which is now before them. It is a time when the fittest men ought to be put into the fittest places, and the opportunity for doing so must not be lost. Let those who, with patient endurance and plodding industry, have been doing—as deputies for the retiring veterans—the duties of offices superior to their own, have now their merits recognised, and those offices with the proper emoluments given them for their zeal. It will not be tolerated that efficient and meritorious men shall be slighted and beclouded by the introduction over their heads of any Higgins's or Dowb's who may happen to have relatives or friends in power. Nepotism is a strong passion in the official mind generally, but it must be controlled; and so far as we are concerned it shall be looked after. It is our purpose to maintain—at all hazards and without reserve—the indefeasible right of the practical, useful, and efficient men of the Civil Service, and also of the Naval and Military Services, to obtain advancement according to their deserts, lingering no longer in the cold shade of aristocratic or class influence. We have in our eye at this moment a Royal establishment, where two or three years ago red-tapery was paramount, and abuses of every kind were rife, which has been completely reformed by the simple investment with superior powers of two practical and working men—men, that is, who will work with their heads, and, if needs be, with their hands too. These indefatigable assistants to a strong-minded and able chief officer have effected savings—by legitimate improvement and judicious economy—which the Treasury know well may be estimated by thousands of pounds. Will these valuable public servants have their indisputable claims to promotion admitted by the Ministry of the day, or will they, as too many other deserving subordinate officers have been, be neglected and left to reflect upon the ingratitude of their country? We shall see. The compulsory 65-years-of-age clause will assuredly create vacancies in the upper stratum of the official department of that establishment; will these active and persevering candidates for elevation be raised thereto, or will patronage step in and close the ranks against them? Vigilantly, in these particular instances, we shall regard the movements of the Treasury, and certainly shall not fail to applaud its decision, provided that decision be in accordance with simple justice. Whenever else the opportunity offers itself for obtaining—as completely as in the cases in question—possession of facts bearing upon promotions *earned* by merit, we entreat members of the Committee—other journalists, that is—to make known the same, and to see that no jobbery or injustice of any kind shall deprive industrious and useful public servants of their fair rewards.

By these means a purification of our great national establishments may be finally obtained, and the various offices in them filled with men qualified in all respects for the varied and important duties pertaining to them. If such effects result from the passing of the Civil Service Superannuation Bill, the year 1859 will become memorable in the annals of social progress, and Mr. Chancellor of the Exchequer DISRAELI will all but immortalise himself.

THE CASE OF HENRY CORT,
AND
HIS INVENTIONS IN THE MANUFACTURE OF BRITISH IRON.

BY

THOMAS WEBSTER, M.A., F.R.S., &c., Barrister-at-Law.

No. III.

DUDLEY appears to have met with the fate of most inventors, in experiencing the opposition of conflicting interests; he complains of the sufferings sustained from time to time during forty years, and his own great charge, pain, and time spent for the general good of his invention for the preservation of Great Britain's wood and timber. The author of the "Metallum Martis," after assigning various reasons that induced him to undertake the invention after the many failures of others, and giving an account of the troubles which he experienced from the destruction of his works by a great flood, "to the joy of many iron-masters whose works escaped the flood, and who had often disparaged the author's invention because he sold good iron cheaper than they could afford it, and which induced many of the iron-masters to complain to King JAMES, averring that the iron was not merchantable," proceeds to give the following account of the progress of the invention:—

"As soon as the author had repaired his works and inventions, to his no small charge, they so far prevailed with King James, that the author was commanded, with all speed possible, to send all sorts of bar iron up to the Tower of London, fit for making of muskets and carbines; and the iron being so tried by artists and smiths, that the iron-masters and ironmongers were all silenced until the 21st of King James. At the then Parliament all monopolies were made null, and divers of the iron-masters endeavoured to bring the invention of making iron with pit-coal, &c., within the compass of monopoly; but the Lord Dudley and the author did prevail; yet the patent was limited to continue but 14 years. After which Act, the author went on cheerfully, and made annually great store of iron, good and merchantable, and sold it unto divers men yet living at £12 per ton. I also made all sorts of cast-iron wares, as brewing cisterns, pots, mortars, and better and cheaper than any yet were made in these nations with charcoal; some of which are extant, to be seen by any (at the author's house in the city of Worcester) that desire to be satisfied of the truth in the said invention.

"Afterwards the author was ousted of his works and inventions before-mentioned by the iron-masters and others wrongfully—over long to relate; yet, being unwilling his inventions (having undergone much charge and pains therein) should fall to the ground and be buried in him, made him set forward his inventions again at a furnace called Himley Furnace, in the county of Stafford, where he made much iron with pit-coal; but, wanting a forge to make it into bars, was constrained, for want of stock, to sell the pig iron unto the charcoal iron-masters, who did him much prejudice, not only in detaining his stock, but also disparaging the iron—Himley Furnace being rented out unto charcoal iron-masters.

"The author erected a new large furnace on purpose, 27 feet square, all of stone, for his new invention, at a place called Hascobridge, in the parish of Sedgeley and county of Stafford, the bellows of which furnace were larger than ordinary bellows are, in which work he made seven tons of iron per week, the greatest quantity of pit-coal iron that ever yet was made in Great Britain. Near which furnace the author discovered many new coal-mines, ten yards thick, and iron-mine under it, according to other coal works; which coal works being brought into perfection, the author was by force thrown out of them, and the bellows of his new furnace and invention by riotous persons cut in pieces, to his no small prejudice and loss of his invention of making iron with pit-coal, &c., so that being, with law-suits and riots, wearied and disabled to prosecute his art and invention at present, even until the first patent was extinct."

In this outline of DUDLEY's career as the successful introducer of the manufacture of iron with pit-coal, may be traced the counterpart of the history of many an inventor struggling with the opposition of rival interests, and the difficulties which his own invention has called into existence. But, notwithstanding these discouragements, DUDLEY continued the manufacture with success, and on the expiry of his patent obtained a new patent (dated 2 May, 14 Car. I, A.D. 1639), in the working of which he became associated with some influential persons, and continued his manufacture notwithstanding the rivalry created by other grants, and amongst these, by an Act of the Commonwealth (A.D. 1651, c. 2) for 14 years to Jeremy Buck, for melting down iron and other metals with stone-coal and other coals without charking, and by the personal influence of favourites of CROMWELL, who attempted the smelting of iron in large clay pots, heated by the flame of pit-coal, like those used in the glass manufacture, and set in large furnaces, but the attempt failed, and DUDLEY, on the accession of CHARLES II., A.D. 1660, being then sixty-one years of age, renewed the application for the renewal of his patent, alleging amongst other things, that the mastery or mystery of the inventions of making iron with pit-coal was not effected and perfected by any man, and that no order having been made thereon, compelling necessity doth constrain him to desist from his inventions, in which he hath taken more pains, care, and charge than any man to perfect his new inventions in these kingdoms, and suffered much ever since the year 1618 for the general good, for the making of iron with pit-coal, and the preserva-

Digitized by Google

tion of wood and timber of Great Britain; but his application was not successful.

No certain information exists as to the quantity of iron made by DUDLEY, but the following extract from the "Metallum Martis" of this working about the middle of the 17th century (A.D. 1650—1660), will be read with interest:—

"Although the author hath not as yet so fully perfected or raised his inventions to the quantity of charcoal iron furnaces, yet the author's quantity being but 7 tons per week at the most, together with the quality of his iron made with pit-coal and sea-coal, hath the most eminent triplicity of iron of all that can be desired in any new invention;—1, More sufficient: 2, More cheap; 3, More excellent—upon which triplicity the author might enlarge, but shall not be tedious, only give me leave to mention that there be three sorts of cast iron. 1, The first sort is grey iron; 2, The second sort is called motley iron, of which one part of the sows or pigs is grey, the other part is white intermixed; 3, The third sort is called white iron; this is almost as white as bell-metal, but in the furnace is least fined, and the most terrestrial.

"Of the three, the motley iron is somewhat more fined, but the grey iron is most fined in the furnace, and more malleable and tough than the other two sorts before mentioned, and of this sort is the iron made with pit-coal (sea-coal for the most part), and therefore more sufficiently to be preferred; 2, More cheap iron there cannot be made, for the author did sell pig or cast iron made with pit-coal at £4 per ton; many tons in the twentieth year of King James, with good profit. Also, the author did sell bar iron, good and merchantable, at £12 per ton and under; but bar iron hath been sold for the most part ever since at £15, £16, £17, and £18 per ton by charcoal iron-masters."

Notwithstanding the success of DUDLEY, the manufacture of iron by the use of pit-coal did not progress, and shortly after the period to which the preceding extract refers, appears to have been practically abandoned till the beginning the last century, when (A.D. 1713) the manufacture of iron with pit-coal was resumed by ABRAHAM DARBY, of Coalbrook Dale, but apparently with no great commercial success, The quantity of iron produced in England had diminished annually from about the middle of the 17th century, though every year witnessed an increased demand for the article, particularly in its manufactured state; recourse was necessarily had to foreign markets, and gave rise to the large annual importation from Russia and Sweden.

The 300 blast furnaces said to exist in the time of DUDLEY, and estimated to make 150,000 tons per annum, were reduced to 59, estimated as making, in 1740, a total amount of 17,350 tons per annum, or less than 300 tons per furnace. It may be inferred that the difficulty and temporary abandonment of the manufacture of iron from pit-coal was due mainly to two causes, the one the inadequate blast, the other the insufficient means of removing the injurious products peculiar to most descriptions of pit-coal. Up to the commencement of the 18th century the attention of enterprising men would appear to have been mainly directed, in consequence of the destruction of the forests and consumption of timber required for other purposes, to the discovery of a new fuel for the reduction of iron from the ore, but in the earlier part of the 18th century, attention was directed to the use of fluxes, and to the addition of ingredients which should render the iron less brittle; little, however, if anything, appears to have been done towards improvement in the subsequent stages as in the manufacture of bar-iron—that, as we may infer from DUDLEY'S account, was still practically in the hands of the charcoal iron-makers.

The erection of a new blast by SMEATON, at the subsequently celebrated Carron Works, led the way to other and further improvements on the introduction of the steam engine, and to a more powerful blast, by which the yield of iron for a given quantity of ore and pit-coal was greatly increased; but England, at the middle of the last century, was still mainly dependent on foreign countries for all the better qualities of bar or malleable iron.

The substitution of pit-coal for wood or charcoal as the fuel, and the improved blast consequent on the application of water and steam power to suitable blowing apparatus, have usually been referred to as two of the epochs in the reduction of iron from the ore, or the smelting of iron in the blast furnace, so as to produce that which has been commonly called crude or pig-iron; and the inventions of HENRY CORT must be regarded as the third epoch in the history of the British iron manufacture, and the first great change in the conversion of the pig into malleable or bar iron.

The dependence of England on foreign countries, consequent on the diminished manufacture of iron, and the increasing demand in this country, was a great stimulus to the inventive genius, and accordingly we find that early in the 18th century, the rendering the nation dependent on its own resources and independent of any supply from foreign parts, was put forward as a great object to be obtained; as, for instance, a patent was granted in 1728 to WILLIAM WOOD for making raw iron, or iron metal prepared in an air furnace with pit-coal, whereby, as suggested by the patentee, "the nation may be supplied with all the iron it requires. and prevent the buying of iron from foreign parts, which amounts to about 20,000 tons yearly, and is most paid for in ready money, to our great disadvantage and loss."

The produce of the blast furnace, commonly called pig iron or crude iron, is converted from cast into malleable iron by the refining furnace, in which the iron was heated and brought to nature or metallized, as it was called, and then worked down or forged by heavy hammers into bar iron. According to the estimate of DUDLEY, there were in his time 500 forges and mills for refining the crude iron and making it into malleable bars, but there are good grounds for supposing this, as well as his estimate of the number of blast furnaces, to be greatly in excess of the real number.

MACINTOSH'S SYSTEM OF NATIONAL DEFENCE.

A CURIOUS and bulky pamphlet, compiled especially for the delectation of "the Honourable the Members of the House of Commons," has just been placed in our hands. It is entitled "Macintosh's System of National Defence; also his Official Correspondence with the British Government, disclosing 'The True Cause' of the Continuation of the late War, from the clashing of the Naval and Military Departments; its Method; its Causes; and consequent Expenses."* This is not a very elegant or lucid title, but it is an ambitious one, and is likely just now to attract attention.

Mr. Macintosh's system of warfare—which mainly consists in creating an artificial fog in order to cover an attack upon a ship or fortress—is understood by most of our readers. On the 13th June, 1853, when we were fast "drifting" war-ward, he first introduced it to the notice of Lord Aberdeen, the Prime Minister, who referred him to Sir James Graham, First Lord of the Admiralty, whose Secretary curtly "thanked" him for his communication. Being a rapid, practical man, he received this rebuff unabashed, and started with a supply of materials to Constantinople, for the purpose of destroying the Russian Fleet at Sebastopol off-hand, for, and by aid of, the Turks. But as war was not declared, Lord Stratford de Redcliffe advised him to return to England, and entrusted him with official despatches to Lord Clarendon. He returned, and by Lord Clarendon's kindness, got an interview with Admiral Berkeley, at the Admiralty, who pronounced the system inglorious (since it was designed to cripple the enemy with little loss to ourselves!), and advised him to return to Turkey, promising to instruct Admiral Dundas to assist him. Off went Mr. Macintosh again, and after some trouble got a council of war called on board the British Admiral's ship in the Bay of Baltshik. Admiral Dundas, however—who was empowered by the articles of war, as Mr. Macintosh suggests to "burn, sink, and destroy,"—refused to employ the new mode of warfare without written instructions from the Admiralty, although not without confidence (according to Mr. Macintosh's statement) in the system. The inventor therefore returned again to England, and learned from Mr. Bernal Osborne that their Lordships were "not prepared to adopt" it.

Baffled thus at home, off goes Mr. Macintosh to Paris, only to find that the Emperor has just before started for Biarritz. The Minister of Marine, however, receives him graciously, and promises him an early trial on a large scale before the Emperor at Boulogne. Returning once more to England, he procures an interview with the Duke of Newcastle, who commends the matter to the Admiralty, who now agree to see the inventor at Portsmouth, and arrange for a trial. When the time for the trial arrives the two Lords are indisposed, and appoint Sir Thomas Maitland, and Mr. Hay, the Admiralty Chemist, to witness and report on the experiments.

"We proceeded on board the *Excellent*," says Mr. Macintosh, "and having shipped a sufficient quantity of the hydrocarbon in a six-oared gig, pushed off towards Porchester Creek, and there discharged on the water a sufficient quantity, which, floating on its surface, was propelled by the wind to about 200 yards, when Sir Thomas Maitland directed me to ignite it, which I did, by projecting a small ball of the metal potassium into it; this had the effect of generating an *impenetrable black suffocating fog*. We pulled up to the burning material and ignited a paper, clearly demonstrating that ships of war could follow up in its wake, without injury to the attacking party; thus enabling squadrons to form up in a line of battle under cover of the black smoke, and when within point-blank range of any land batteries, to disembark troops and take possession, or simultaneously open a concentrated fire and entirely destroy them. I may here mention that no animal can breathe within its folds: consequently, on the smoke entering the embrasures, it would naturally compel all the gunners to beat a quick retreat, thereby leaving the enemy's forts at the mercy of the attacking squadron."

What Sir Thomas Maitland reported, Mr. Macintosh could never find out. He was told that copies of the report had been forwarded to the Admirals in the Black and Baltic Seas, but these officers both deny that they were ever received by them. The Admiralty finally, in 1855, gave Mr. Macintosh £50 (!) to cover all expenses, and thus ended his *first* correspondence with them.

Other correspondence with both the Admiralty and the War Department followed, with a similar result, except that a cheque for £1,000 was obtained from Lord Panmure as a consideration for the unprecedented, and, as we think, unjustifiable seizure of Mr. Macintosh's patent—a poor remuneration for such an act. This seizure was made after the official experiments at Shoeburyness had, as we have a right to assume, proved the great value of the invention. But it is not our intention to trace Mr. Macintosh's efforts and obstructions further. It seems to us, however, that Admiralty Lords, and War Ministers, and Ordnance Officers have dealt with his system from the first without that sense of responsibility which we have a just right to expect in public servants, however exalted their positions may be. Their obstinate secresy and reticence leaves even their friends without the power of defending them.

We have now to notice a proposition of Mr. Macintosh's. He suggests that an Incendiary Steam Brigade should be at once established, and attached in part to each of our fleets, as an

* London: printed by W. Clowes and Sons, Stamford Street, and Charing-cross. 1859.

Digitized by Google

auxiliary power of attack. This brigade is to consist of iron steamers, furnished with compartments or tanks filled with coal-tar naphtha. When sea-face batteries are to be attacked, he would start one of the small steamers, under the control of two or three men, towards the enemy's works. When nearly within range of their guns, they would light a time-fuse in connection with gunpowder, and abandon the vessel, leaving her to proceed towards the batteries. The explosion would disperse the combustible liquid over the surface of the water, and igniting it at the same time, would thus produce a dense black smoke or vapour. This would be carried by the wind—an on-shore wind being selected for the purpose—against the sea-faces, and through the embrasures of the batteries, driving the enemy out before it. Other modes of operation are suggested.

Now, there is surely sufficient reason in this proposal to gain for it a practical trial. Such a system of operation would unquestionably be cheap, and it might be effectual. We venture to assert that, as a mode of warfare, it commends itself more strongly to the unbiassed mind than the present plan of blowing little balls of iron against vast stone structures; and we see no reason why the one process should be considered less dignified than the other. With this system at our command the fortresses of Cherbourg and other continental ports, would be so far brought within the power of British fleets as to give us a better right to influence the councils of Imperial Courts than we now seem to possess.

For our part we would therefore ask urgently for a fair and full trial of Mr. Macintosh's system.

Parliamentary Proceedings.

CONDENSED FOR THE "MECHANICS' MAGAZINE."

THURSDAY, FEBRUARY 17.

HOUSE OF COMMONS.

THE DUTY ON WOOD.

Mr. MITCHELL gave notice that on Thursday, March 3, he should move the repeal of the duty on wood.

THE TELEGRAPH TO ALEXANDRIA.

Mr. CRAWFORD asked the Chancellor of the Exchequer whether Her Majesty's Government had concluded a convention with the Austrian Government for the establishment of a line of telegraphic communication with Alexandria, on the principle of a financial guarantee on the part of this country; and, if so, when a copy of the said convention would be laid on the table?

The CHANCELLOR of the EXCHEQUER said it was not true that Government had entered into a convention with the Austrian Government, but the terms on which such a convention would probably be concluded had been settled, and when the convention was concluded it would, of course, be laid on the table of the House. If it were carried out on the terms which had been agreed upon, it would include a financial guarantee, but not an unconditional guarantee.

LAND TRANSPORT CORPS.

General CODRINGTON asked the Secretary of State for War, whether the rank given, "pending Her Majesty's pleasure," to officers of the Land Transport Corps, by general orders in the Crimea, was to be confirmed to them; and, if so, from what date?

General PEEL said he had recommended the Treasury that it should be granted, and he was in correspondence with the Treasury on the subject.

FRIDAY, FEBRUARY 18.

HOUSE OF LORDS.

THE CLOCK IN THE CLOCK TOWER.

Lord CAMPBELL gave notice that he would take an early opportunity of asking the Government whether there was any prospect of the clock in the clock tower ever going. From the time of the Plantagenets there had been a clock tower in Palace-yard for the purpose of warning judges, counsel, and witnesses, and all persons concerned, to attend at the proper hour, and assist in the administration of justice. That clock tower had disappeared, and a noble one had arisen in its place, but as yet no clock struck the hours. He hoped something would be done to remedy this evil. He did not say it was a *striking* reproach so far as the administration of justice was concerned, but it certainly was a standing reproach.

HOUSE OF COMMONS.

THE POISONS BILL.

Sir G. PECHELL asked the Home Secretary whether he would be so good as to postpone the second reading of the Sale of Poisons Bill for a few days?

Mr. WALPOLE said, it would be convenient to take the second reading to-night unless the hon. and gallant member objected to the principle; but he would postpone the committee on the Bill until that day week.

SUPPLY OF GUANO.

Mr. CAIRD put some questions to the Government, with the view of urging them to aid in obtaining the consent of Peru to an open trade in guano.

NEW FOREIGN OFFICE.

A discussion on this subject was led off by Sir B. Hall, who was followed by Lord J. Manners, Sir G. C. Lewis, Mr. Tite, Mr. Coningham, and Lord Palmerston. They merely reiterated their well-known opinions.

SUPERANNUATION BILL.

On the motion that this Bill be read a second time,

Mr. J. WILSON said he intended to move an amendment in committee, to which he believed the Government would not object.

Sir H. WILLOUGHBY complained that a Bill of so much importance was pressed forward at so late an hour (near 12 o'clock). He believed that the Bill would throw an enormous burden upon the country.

After some remarks from Sir S. Northcote (for the Government), Mr. Serjeant Deasy, and the Attorney-General for Ireland,

General CODRINGTON expressed a hope that the Bill was so framed as to include within its scope artificers and labourers regularly employed in the Government establishments; and he asked if its operation was to be retrospective or otherwise?

Mr. GROGAN also hoped that the Bill would include the large class of supernumeraries employed in almost every department of the Government.

The Bill was read a second time.

SALE OF POISONS BILL.

This Bill was read a second time.

MONDAY, FEBRUARY 21.

HOUSE OF COMMONS.

THE NELSON MONUMENT.

Mr. LAURIE asked when the lions were expected to be placed on the Nelson Column, and why the execution of them was intrusted to Sir Edwin Landseer, instead of Mr. Lough, the sculptor originally appointed by the committee; also whether it was intended to continue the two water-spouts before the National Gallery.

Lord J. MANNERS said that Sir Edwin Landseer was at present engaged in modelling the lions, and it was hoped that they would be placed in their position at no distant day. Sir Edwin Landseer had been chosen because Her Majesty's Government were convinced that the task could not be intrusted to more skilful hands. With regard to the last question, the hon. gentleman had given him no notice of it, and the subject had not yet been brought under his consideration.

NAVAL ESTIMATES.

Sir J. PAKINGTON, who had given notice to introduce the Navy Estimates on Friday next, appealed (with but little effect) to the members for Montrose and Berwick, and to the member for Sandwich, all of whom had given notice of motions "on going into Committee of Supply," to yield their right of precedence upon that occasion, in order that he might make his statement. The duty of which he had given notice was an arduous and a difficult one, and it would be impossible to discharge it satisfactorily if he had to commence at a late hour, and after three important subjects had been discussed.

SUPERANNUATION BILL.

This Bill went through committee *pro forma*.

TUESDAY, FEBRUARY 22.

HOUSE OF COMMONS.

DIFFERENCES BETWEEN MASTERS AND OPERATIVES.

Mr. MACKINNON having presented a petition on the subject, said, as he believed that there was no opposition to the motion which he was about to make, he should reserve his observations until the second reading. He would simply express his belief that strikes, which were injurious alike to master and to man, could only be prevented by a system of equitable conciliation. He moved for leave to bring in a Bill to establish equitable councils of conciliation and arbitration to adjust differences between masters and operatives.

Leave was given to bring in the Bill, and at a later period of the evening it was brought in and read a first time.

ADULTERATION OF FOOD.

Mr. SCHOLEFIELD obtained leave to introduce a Bill to prevent the adulteration of articles of food or drink.

The Bill was subsequently read a first time.

PUBLIC RECREATION.

On the motion of Mr. SLANEY, leave was given to bring in a Bill to facilitate grants of land to be made near populous places for the use of regulated recreation of adults and as playgrounds for poor children.

The hon. member afterwards brought in the Bill, and it was read a first time.

THE EDUCATIONAL REPORTS.

After much discussion it was arranged that the Reports of the Examiners in the Educational Department should be published in full, the examiners being, however, instructed to make them brief and pertinent.

REPRESENTATION OF GREENWICH.—We have reason to believe that Sir John Pakington, the First Lord of the Admiralty, purposes standing for the Borough of Greenwich on the retirement of Sir W. Codrington. This step is to be taken in consequence of the proposed disfranchisement of Droitwich, which Sir John at present represents. If nothing particularly unfavourable to the present Government happens before April, the return of Sir John will be certain.

Literature.

A Manual of Applied Mechanics. By WM. JAS. MACQUORN RANKINE, LL.D., C.E., F.R.S.S., L. & E., President of the Institution of Engineers in Scotland, and Regius Professor of Civil Engineering and Mechanics to the University of Glasgow. London and Glasgow: Richard Griffin and Co. Publishers to the University of Glasgow. 1858.

(SECOND NOTICE.)

IT is now time to give some account of the contents of this work, and its method of treatment. We shall not dwell on the preface, which gives the substance of a discourse, read before the Senate of the University of Glasgow on the 10th December, 1852, and of an inaugural lecture, delivered to the class of Civil Engineering and Mechanics in that University on the 3rd January, 1856. It is needless to remark that its object is the settlement of the much vexed question of the real harmony between *theory* and *practice*. There is doubtless much misapprehension with respect to the limits of the realms of each of these, and much has been written ignorantly and in anger by the disputants on both sides. Theory in the higher departments of applied mechanics has frequently proved but an unsafe guide; and practice unaided by theory, has sometimes made miserable failures. Hence the practical man has been too prone to twit the theorist on the unsubstantiality of his labours, and the theorist, on the other hand, has made too much of the occasional failures of his opponents. Consequently both parties have been driven to adopt their several extremes—the one, that the study of the mathematical theory of mechanics is absolutely useless for practical purpose, and the other, that the sound practice of the mechanical arts is utterly impossible without theory. The truth, however, seems to be, that the sound mechanical practice long preceded a knowledge of the principles. The ancients, without one atom of sound theory, were conversant enough with the most effective mechanical appliances requisite for architectural and other structural purposes. A conception of the true nature of force and laws of motion, which, according to rigid theorists, ought to have preceded the invention of any machine, is of very modern growth. A most remarkable instance of this precedence of invention to sound theory is afforded by the history of the steam-engine, the discovery of which has entirely given a new complexion to the civilization of the nineteenth century. James Watt invented this machine, or at least invented all those contrivances which have given it its practical value—and no material improvement in its main parts has since been discovered—without the slightest knowledge of the true mechanical principles on which it depends. Nay more—the theoretical engineers of this country, as Tredgold, spent much useless ingenuity in inventing empirical quasi-scientific formula to reconcile the real with the theoretical work of the steam engine. It was reserved for a French officer of Engineers, the Comte de Pambour, within the last twenty-five years, to explain its true theory. The inventive genius often exists in a man entirely separate from the power of theoretical analysis, and it is no exaggeration to say that in almost all cases of great discoveries which have exerted marked influence on the state of mechanicalart, thediscovery has preceded the theoretical explanation, and that in very few instances has the discovery been the consequence a of precedent theory. The high vaunts of some exalted theorists are so manifestly contradicted by fact, that it is no wonder that practical men have been led to deny the value of their science altogether. But are we, then, to conclude that theory is of no value? To assert this would be, in our opinion, to commit as great an error as to insist on its exclusive importance. Each explanation of a practical result raises the whole fabric of applied science another stage; it raises the stand-point from which both theorists and practical men

Digitized by Google

direct their future efforts. Without being aware of it, the man of practice becomes imbued with a goodly portion of the theoretical principles which it is the object of mathematics to supply; and he is saved from many a pitfall, and indirectly guided to many a highway in his professional career, by an unconscious following in the wake of those very theorists whom he professes so much to despise, and whose teaching he cannot practically set at naught without exposing himself to the risk, nay certainty, of failure.

In many extensive departments of applied science the failure of theory has arisen, not from any error in the principles (these have endured far too stringent tests to be capable of doubt), but from a want of accuracy in the experimental facts on which the theory has been based. To take a well-known example—the theory of fluid resistances. The mathematical application would be perfect if only the experimental law were satisfactorily established. From an insufficient induction, it was formerly considered proved that the resistance of fluids varies as the square of the velocity. Were this strictly true, the best form of a ship to overcome the resistance with least motive power would be as certainly established as the explanation of the motion of the heavenly bodies. This experimental law, however, has been discovered to be baseless, and no satisfactory substitute has been found; and hence theory, having no solid foundation on which to rest, cannot but fail in supplying a true interpretation of the motion of vessels in a fluid medium. The fault here clearly does not lie with the mathematical investigation, but with the experimental facts on which the theory has been based, and which have hitherto eluded the grasp of the observer. The same remark applies to most of the other cases in which theory is presumed to have failed. Yet surely it cannot be a disadvantage to a practical man—it cannot be other than a great advantage—that he should entertain clear and distinct ideas of force, of motion, and of their various combinations, and the mode in which the numerous facts which the exercise of his profession brings under his notice are theoretically explained. On the one hand, let the theorist abate somewhat of his exorbitant pretensions, and confine his promises within the region which experience has assigned them; and, on the other, let the man of practice cease to condemn everything beyond mere instinct, and allow that there is some use in understanding the rationale of ascertained facts, and there will soon cease to be that divergence in the view of these two classes of men which has long been felt to be amongst the most effective bars to the progress of applied science. A little mutual forbearance, a little abatement of the pretension of the exclusive importance of his own study which so frequently characterizes both, would soon smooth the way to a better appreciation of each other, and to harmonious co-operation.

Professor Rankine ought to speak with great weight on such a subject, as he has himself received the education of a Civil Engineer, and may, therefore, be supposed to combine in his own person the advantages of theory and practice. With many of his remarks we cordially agree, and especially we commend his THEORY of the mode in which "Applied Mechanics" should be taught; and we confess that after his admirable statement of the objects for which the Chair of Civil Engineering and Mechanics, which he fills, was designed, we entertained sanguine hopes that his work would offer the long-sought solution of the apparently hopeless problem of supplying the engineer with a sound and simple explanation of the principles of his craft. His appreciation of the desiderata for such a task is so just, that we cannot resist the temptation of laying before our readers the whole passage in which he treats this *in extenso*. After speaking of purely scientific and purely practical instruction, he goes on to say:—

"The third and intermediate kind of instruction which connects the first two, and for the promotion of which this chair was established, relates to the application of scientific principles to practical purposes. It qualifies the student to plan a structure or a machine for a given purpose, without the necessity of copying some existing example, and to adapt his designs to situations to which no existing example affords a parallel. It enables him to compile the theoretical limits of the strength and stability of a structure, or the efficiency of a machine of a particular kind—to ascertain how far an actual structure or machine fails to attain that limit—to discover the causes of such shortcomings—and to devise improvements for obviating such causes; and it enables him to judge how far established practical rule is founded on reason, how far on mere custom, and how far on error.

There are certain characteristics in the mode of treating the subjects by which this practical, scientific instruction ought to be distinguished from instruction for purely scientific purposes. In the first place, it will be universally admitted that, as far as is possible, *mathematical intricacy ought to be avoided.*

"In the original discovery of a proposition of practical utility, by deduction from general principles and from experimental data, a complex algebraical investigation is not merely useful, but indispensable; *but in expounding such a proposition as a part of practical science, and applying it to practical purposes, simplicity is of the* FIRST IMPORTANCE; and in fact, the more thoroughly a scientific man has studied the higher mathematics, the more fully does he become aware of this truth; and I may add, the better qualified does he become to free the exposition and application of scientific principles from mathematical intricacy.

"In fact, the symbols of algebra, when employed in abstruse and complex theoretical investigations, constitute a sort of thought-saving machine, by whose aid a person skilled in its use can solve problems respecting quantities, and dispense with the mental labour of thinking of those quantities denoted by the symbols, except at the beginning and end of the operation. *In treating of the practical application of scientific principles, an algebraical formula should only be employed when its shortness and simplicity are such as to render it a clearer expression of a proposition or rule than common language would be, and when there is no difficulty in keeping the thing represented by each symbol constantly before the mind.*"—Preliminary Dissertation, pp. 9 and 10.

We fully and cordially accept this definition of what ought to be the aims of a treatise on "Applied Mechanics," as also what the author states in the introduction with regard to such a treatise, viz., that it "must commence by setting forth these first principles which are common to all branches of mechanics, but it must contain only such consequences of those principles as are applicable to purposes of art."

We propose now to examine how far Professor Rankine has complied with his own canons in the work before us, and has studied simplicity, clearness of expression, abstinence from unnecessary algebraic symbols, and from pursuing theory into purely imaginary and unpractical results, in this manual which he proposes to place into the hands of the practical man as his *vade mecum*.

The general divisions of his subject are six, viz.:—

1. First Principles of Statics. 2. Theory of Structures. 3. First Principles of Cinematics, *i.e.*, geometrical comparison of motions with other, without reference to causes. 4. Theory of Mechanism, or the modification which *motion* undergoes by being transmitted through machines. 5. First Principles of Dynamics, and 6. Theory of Machines considered, *i.e.*, as transmitting and modifying *force*.

We shall first address ourselves to the treatment of the "first principles which are common to all branches of mechanics." Here it was the author's duty—for which, as an expert mathematician, he might be deemed especially qualified, according to his own showing—to be clear, precise, and as free as possible from *abstruse mathematical* investigation. In our opinion he is just the reverse of this: in his definitions he is often indistinct or illogical, and in his general expositions of principles he is more abstruse and confused than any author of repute with whose works we are acquainted.

For instance, to go no further than the first page of the Introduction, what could be more confused or illogical than his definition of matter? "Matter (considered mechanically) is that which fills space." The natural and logical meaning which this conveys is, that space is filled with a something, and that the something which fills it is matter. This, we know, is not what is meant; which is simply this,—that whatever so fills any portion of space as to exclude anything else from occupying the same portion of space at the same time is *matter*; but to bring this notion within our author's definition requires so many implied limitations and explanations as to render it, for the purposes of a definition, useless.

Take, again, the definition of direction and line of action of force. "The direction of a force is that of the motion which it tends to produce. A straight line drawn through the point of application of a single force, and *along its direction*, is the line of action of that force." Now, what difference could this definition convey to the mind of a learner between line of action and direction? The more simple idea to a tyro is that of the line of application—viz., that line in which the force applied to the point of application would tend to move that point—supposed material and separated from the rest of the body—if unresisted; and, when he has mastered this, he will be prepared to go on to the idea of any straight line parallel to the line of application as the *direction* of the force—the sense in which mechanical philosophers usually understand this term. This distinction is by no means conveyed by Professor Rankine's words.

Again, the definition of the resultant of any number of forces is open to grave objection, and is almost certain to mislead and confuse a learner.

We are told—"The resultant of any number of given forces, applied to *one body*, is a single force capable of balancing that single force which balances the given forces." This is true enough of the resultant of forces applied to *one point* of a body: but it may and does frequently happen that there is no single force capable of balancing all the forces applied to a body. Professor Rankine doubtless meant by the words 'one body,' one point; but, by such an implied limitation, he renders his definition inexact, and consequently useless.

We shall only instance one more definition, viz., that of *Specific Gravity*. According to our author "the Specific Gravity of a body is the *intensity of its weight*, or the weight of an unit of its volume; for example, the weight in pounds of a cubic foot of the volume of the body. The *pound per cubic foot* is the most convenient unit of specific gravity for practical purposes; but in tables of specific gravity, a special unit is SOMETIMES employed, viz., the weight at a fine temperature of unit of volume of water."

Now here our author is open to graver censure almost than in the peceding cases. In them he has probably been guilty of little more than carelessness; here there is an apparently conscious alteration of the usual meaning of a scientific term. The Professor could scarcely have been ignorant that the specific gravity of a body *always* has reference to the weight of a unit of volume of water, and is, in fact, the *ratio* which the weight of a unit of volume of the body bears to that of the unit of volume of water; and that by the term specific gravity is never implied the number of pounds weight per cubic foot. We cannot therefore acquit him of a deliberate intention of endeavouring to *amend* the received definition—an act of considerable presumption even in a scientific man of the highest repute, and sure to lead to nothing but confusion. It would doubtless be convenient to have a term for the number of pounds weight per cubic foot, and *specific weight* might be advantageously employed for the purpose; but it argues no small amount of self-esteem in an author to endeavour to wrest a term which has long been employed by the scientific world in a definite sense to serve another purpose. The habit of mind which this argues—aiming at originality at whatever cost—may probably account for many of the defects of the work before us, the further examination of which the limit of our space warns us must be put off to a future occasion.

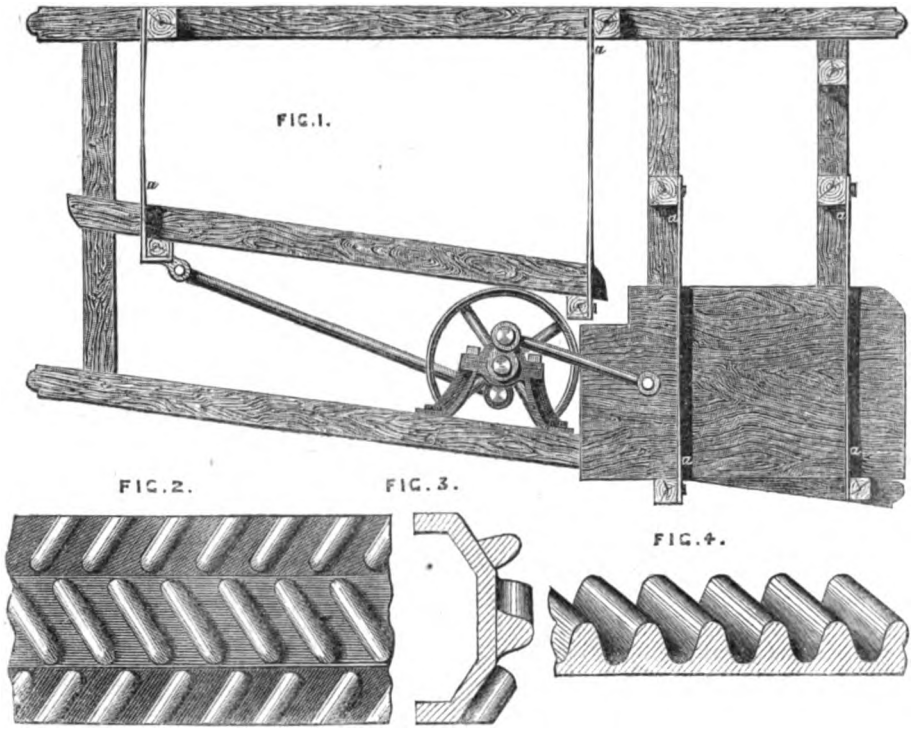
MIDWORTH'S IMPROVEMENTS IN THRESHING AND DRESSING MACHINES.



MESSRS. J. and W. MIDWORTH, Engineers, of Newark, have introduced the following improvements (the invention of Mr J. Coulson, of that firm) into the threshing and dressing machines patented and manufactured by them. The improvements consist first in forming the springs or bars by which the shoes, riddles, and shog-boards of the sifting or riddling apparatus of threshing and dressing machines are suspended, thicker at the ends than at the middle,—that is, tapering from the ends towards the middle,—whereby greater ease and freedom of motion are obtained in the moving parts of the apparatus. The said springs or bars may be formed of steel, wood, or any other suitable material. This improvement is illustrated in Fig. 1 of the annexed engravings, *a a* being the tapering springs. The second improvement consists in forming the beating surfaces of the beaters of the threshing machines of a half-octagon form in section, three of the sides being furnished with oblique ridges or projections, placed alternately in opposite directions. This improvement is illustrated in Figs. 2, 3, and 4, which need no explanation.

NORTON'S SUBMARINE CARTRIDGES.

CAPTAIN NORTON has this week submitted to us an invention of his for discharging shells, powder, caissons, and other like bodies beneath the water. It consists of one of his frictional igniters enclosed in a caoutchouc cover, so arranged that while no water can enter, the frictional rod of the igniter can be readily drawn between the igniting substances at any required moment, thus effecting the discharge. Such a contrivance would, we think, be more handy for blasting under water than either electrical appliances or Pickford's fuse.

CHROMO-LITHOGRAPHY.

THE line of demarcation which separates the results of art from those of mechanical ability must be always more or less capable of definition. We have but to know the means used to produce certain pictorial effects at once to determine the question. But a knowledge of the means is not always at hand, and many a mechanical production may pass current as a work of art in the absence of the requisite information. Under similar circumstances, prints, principally mezzotints very highly coloured in oil, deceived all but the best judges during the latter part of the last century; and although it may be questioned whether these combinations of the engravers' skill and the talent of the painter were not works of art after all, it must be admitted they were not what they were intended to represent, and as such, when discovered, were treated with considerable contempt, or incontinently destroyed. The works produced by the new process of chromo-lithography do not enter the world with any such deceitful purpose, but curious enough their very closeness or *vraisemblance* to the originals from which they are taken is the especial boast and pride of those to whom they owe their creation. How they fare, and whether they pass as the genuine coin after they get far beyond the guardianship or espionage of those who can distinguish the originals from the duplicates it is not for us to enquire, but that they are eminently capable of deceiving the many no one can have a doubt who has watched the progress of chromo-lithography during the last few months.

Messrs. Rowney, the artist colourmen of Rathbone-place, are responsible for this train of thought, which has been occasioned by an inspection of a large collection of chromo-lithographs at their establishment—so large, indeed, as to necessitate a tolerably sized gallery being devoted to their especial exhibition. Messrs. Rowney were amongst the first to recognise the capabilities of "chromo," and long and diligently have they exerted themselves to produce *fac-similes* of esteemed works of modern artists which should vie with the works themselves. Their success, we should imagine, has been almost beyond their own sanguine hopes, for surely they never could have been bold enough to anticipate a period when they could dare to place side by side the proofs of their presses with the "touch-endowed and genius-inspired" *chef-d'ouvres* of a Stanfield, a Roberts, a Cattermole, or even a Rowbotham or a Richardson. This, however, they are doing, and are not alone in their temerity—the Messrs. Hanharts, of Charlotte-street, Fitzroy-square, sharing in a practical challenge to art that would have been a few months since deemed a Quixotic impossibility.

Our praise of chromo-lithography—or rather its evidences—is not unqualified. It possesses a great mission for good or ill, as an educational power, and we fear from what we have seen in some of our art repositories, a positive pandering to bad taste is already prevalent in this new and most pleasing discovery. Attempts to copy Turner, in which we are reminded of the florid poll-parrot school of mantel-piece art—haply long since in its decadence—almost blind us with their meretricious absurdities, while in copies from other masters, "all trees are green, all waters are blue, and all roads are red," forcibly reminding us of Charles Lamb's admirable criticisms of the first attempts of his school-boy days to rival Gainsborough and Moreland.

LAYING-OFF;
OR,
THE GEOMETRY OF SHIP-BUILDING.
No. III.

HAVING briefly considered the general nature of the principle of projection, we shall proceed to its application to ship-drawings. On inspecting one of these, we shall see that although the different parts of the drawing bear the same relation to each other as do the corresponding parts of the ship represented, yet the whole is on a much smaller scale—generally 1-48th of the real dimensions: the drawing is therefore the projected outlines of a miniature ship, the proportion of the size of which, to that of the real vessel, is known. As the sheer drawing of a boat is of the same nature as that of a ship, and the former suits our present convenience, we have given it (page 140), but we shall speak of it generally as though it were that of a ship.

There will appear at first sight but little similarity between the diagrams of the preceding articles and the present drawing, but we shall see as we proceed how closely they are related. The drawing marked SHEER PLAN is a projection of the outlines of the ship upon the vertical plane which is supposed to pass quite through the middle of the ship, cutting her into two similar and equal portions; that marked HALF-BREADTH PLAN is a projection of the same outlines upon the horizontal plane, which is in this case taken, not parallel to the water-lines, but at right angles to the frames of the boat, and at the height of the upper edge of the rabbet of keel amidships. We shall recur to this hereafter. The line in which these two planes intersect is marked, in accordance with our previous practice, *L T*. But the horizontal plane of projection is displaced. The proper position of the half-breadth plan would be that in which the line *L T* in it coincided with the *L T* of the sheer plan; but for the sake of convenience, the two sets of projections are separated, and not only separated—the horizontal plane is turned completely over. It would be possible to record every point in the ship on these two planes, but in order to prevent confusion, a second vertical plane of projection in introduced at right angles to the former, and is called the BODY PLAN.

It is to be observed that any body may be said to be projected when such a number of points and lines in it have been projected as will completely determine its form. To make a projection drawing of a sphere, it is only necessary to project the centre on both the planes, and to describe a circle on each with the projection as centre, and with a radius equal to that of the sphere. These two circles will completely determine the position and dimensions of the solid. Similarly, a cone would be determined by projecting the apex and base; and a cube by the delineation of one of its faces on each of the planes. There is no such regularity in the form of a ship, yet it is sufficiently regular to make the number of points requiring to be projected comparatively small. It will be seen in the first place, that since both sides of the ship are similar and equal, it is only necessary to obtain projections from one of them. For the sheer plan the starboard side is generally taken for this purpose, and for the half-breadth plan the larboard side.

A number of planes are now chosen, cutting the ship into sections, and the shape of the outer surface of the ship being indicated on the planes of projection at each of these sections, the shape of the entire outer surface of the ship is assumed

Digitized by Google

to be known, and if the directions of the sectional planes are well chosen, and they are sufficiently numerous, the shape of the ship is completely determined by them; for at all such sections the curvature of the surface of the ship is continuous and *fair;* and just as only one straight line can be drawn through two points, and only one circle through three points, so there can be but one *fair* curve drawn through each series of detached points selected by the shipbuilder from the surface of the ship, and that curve is found from the given series of points by laying a thin batten upon the paper, and bending it until it passes through all the points; or by selecting a thin piece of wood called a mould, the edge of which is curved, and is of such a curvature that it will unite four or more of the given points.

FIG. 12.

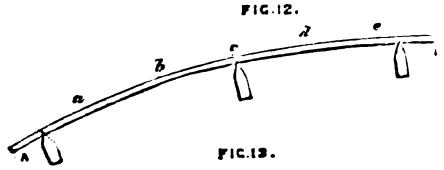


FIG. 13.

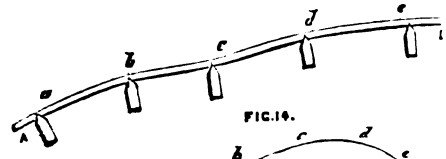

FIG. 14.

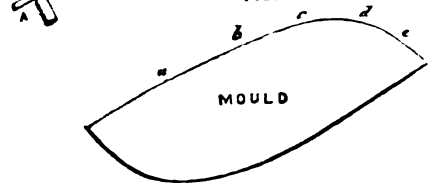

For example, suppose it were known that in one of the sections of the outer surface of the ship there were points occupying the relative positions *a, b, c, d, e*, and it were required to show the complete *line* of section of this surface. To obtain this it would only be necessary to bend the batten *A B*, Fig. 12, by means of lead nippers, until it passed through all these points, then, with a pen or pencil, to describe the curve *a b c d e*.

If one of the points should lie within the others, as in Fig. 13, making it necessary to bend the batten in a hollow, it may be concluded at once that the points have not been correctly determined, and that they cannot be points in one of the sections of the ship.

It requires a considerable degree of practice to be able to detect the least unfairness in the batten, but the draughtsman is always required to do this. If the points are disposed so that a batten could not be bent round them, as in Fig. 14, a mould is employed as represented in that Figure. Moulds are, however, less reliable than battens, as a batten of tolerable thickness will resist any attempt to force it to an unfair curve; whereas, unless the several lengths of a curve described by moulds are well scarphed together, there is great danger of getting in an unfair line. If this occurs in the design on the small scale, the consequence will be, that when it is enlarged on the mould loft floor, the unfairness will become apparent, and it will be necessary, in rectifying it, to depart from the design; on the other hand, should the lines on the floor have any unfairness, it will appear also in the ship, and will lessen her value.

The most obvious direction in which to cut the ship is horizontally, *i. e.*, by planes parallel to the surface of the water, and from one to three feet apart. The curves in which these planes cut the outer surface of the ship are called *water-lines*, and as they show the course which the water travel ing horizontally past the ship is compelled to take, they are generally the first lines drawn in by the architect after the form of the midship section is determined. *N O* (p. 140) is the trace upon the vertical plane of the plane of the water's surface when the boat is laden; it is also the vertical projection of the *load-water line*, or of the curve in which the outer surface of the vessel is cut by the plane of the water. The horizontal projection of this line is *e h*, which, it will be seen, is not the true shape of the line, because the plane of the water's surface is not parallel to the plane of projection; and whenever a ship is designed to draw more water aft than forward, or is not on an *even keel*, and the plane of projection is taken through the upper edge of the rabbet of the keel, then the *water-lines* are not projected in their true shape. What is true of the line (*e h*, *e' h'*) is true also of the parallel lines (*f i*, *f' i'*) (*g k*, *g' k'*). But it may be said, Why is not the horizontal plane taken parallel to the plane of the water, that we may see the true shapes? The answer is, that the frames or ribs of the ship are perpendicular to the keel, and it is convenient to make the transverse sectional planes coincident with the sides of these frames, and to take the third plane of projection for the body plan parallel to them, that they may be projected in their true shape for the purposes of laying-off: this renders it necessary to take the horizontal plane at right angles to these ribs, and inclined to the plane of the water. It will be seen that it is not only the shape of the water-lines which is affected by this choice of the planes of projection; but the transverse sections, including the midship section, although they give the shapes of the ribs, are not those which the *constructor* would like to see. He would wish to see, and to be able to measure, the greatest transverse section of the ship, *at right angles to the line of motion, i. e.*, at right angles to the surface of the water—and he would prefer that all the transverse sections should be vertical.

On this account, especially when the set by the stern is considerable, as is the case in yachts, the constructor has a drawing made on a peculiar principle. He takes his horizontal plane really horizontal or parallel to the surface of the water, and his transverse sections and third plane of projection perpendicular to it. By this means he obtains the true shapes of the water-lines, and of the vertical transverse sections. The number of square feet which he finds by calculating the area of the *projection* of the load-water section is then the real area of that section, and the calculated area of the midship section is not, as it would otherwise have been, the area of a surface oblique to the horizontal, but that of the greatest *vertical* transverse section. Such a drawing is called a construction drawing. But for the reasons we have stated above it cannot be placed in the hands of the draughtsman to be expanded on the floor, as the transverse sections do not give the forms of the ribs, and he would be unable to make the moulds. This drawing has therefore to be converted into a building drawing referred to the planes of projection shown in our figure. As the construction drawing has no immediate connexion with our subject, and as it is, moreover, very rarely made, we shall not describe it further.

The transverse sections of which we have spoken are marked "dead flat" (which is the midship or greatest transverse section), in the fore body *A, B*, and *C*, and in the after body 1, 2, and 3, together with the transom or terminal section of the boat. It will be seen that the ordinary vertical and horizontal projections of these sections are straight lines, because they lie in planes perpendicular to both these planes of projection; while on the third plane they are projected in their true shape. The line *X Y* in this plane is that in which the third plane intersects the vertical plane, and *Y Z*, that in which it intersects the horizontal plane. The transverse sections of the *fore* body are projected on this plane, but as those which lie abaft the midship section would fall upon the foremost sections and cause confusion, they are swung round and shown together with the midship section on the opposite side of the axis *X Y*.

The gunwale or upper boundary of the boat is a line of double curvature, *i. e.*, is curved both outwards and downwards; it is, however, determined by its projections (*a' l' b' d'*, *a l b d*), just as plane curves are. Such lines are called *sheer lines*. It may sometimes happen that all these curves are quite fair, and yet, in consequence of too great fulness in one or more of them, there would be an unfairness in the surface enveloping them. The only way of discovering whether this is so, is to cut across them all by new planes. Planes taken in this way parallel to the vertical plane, cut the surface in lines, the foremost portions of which are called *bow lines*, and the after portions *buttock lines;* for example, (*m b*, *m' b'*), (*n d*, *n' d'*) are bow lines, (*m a*, *m' a'*) (*n e*, *n' c'*), continuations of the same lines, buttock lines. Vertical projections of the same lines are shown in the body plan by vertical dotted lines. The ship is cut again by planes oblique to the vertical and horizontal planes, but at right angles to the plane of the body. The lines in which such planes cut the surface are called *diagonal lines;* *o p q* is the horizontal projection of one of these lines, and *p' q'* or *p' o'* its projection on the plane of the body. It frequently happens that the diagonal plane in the after body is taken for convenience with an obliquity, differing from that in the fore body. The double plane is made to enter both bodies at the point *p'*, so that the horizontal projection would be a continuous line, and the lines *p' q'*, *p' o'*, representing the vertical projection, would still be straight, but would be inclined at different angles to the axis, and would not, as now, meet it in the same point. To avoid confusion we have not shown the projection of this line on the vertical plane. The curved lines crossing the sections in the fore body, and marked *h' i'* and *k'*, are the projections on the plane of the body of the foremost portions of the water-lines, and those marked *e'*, *f'*, *g'* are the projections on this plane of the after portions of the same lines. The curved lines *l' d'* and *l' a'* on the plane of the body are the projections on that plane of the sheer line (*a l b d*, *a' l' b' d'*).

There is yet another kind of sectional line which we have not shown, that is, the *level* line. It is obtained by cutting the ship by planes at right angles to the planes of the ribs. The projections of these lines in the vertical plane and in the plane of the body are straight lines parallel to the axis, and in the horizontal plane curves of the true shape of the sections.

It will be seen from the nature of projections that the perpendicular distances from the axis of the projection of the points of intersection of the transverse sections with the water lines, sheer lines, and diagonal lines are respectively the same in both the body and half-breadth plans, so that with the aid of the sheer plan, the body plan can be constructed from the half-breadth plan, and *vice versâ*. The heights of the corresponding projections of these same points above the axis in the sheer and body plans are also equal, and the projections on one of these planes may be obtained from those on the other. So also the heights above the axis of the projections of the points of intersection of the several transverse sections, with the buttock and bow lines, are the same in both the body and the sheer plans; and further, the distances from the midship section of the projection of the points of intersection of the water-lines with the buttock and bow lines, are the same in the sheer and half-breadth plans: the curves in the sheer may, therefore, be obtained from the half-breadth. We have joined, for example, by dotted lines, two corresponding points on the two plans in the intersection of the load-water line with the outer bow and buttock lines.* In strict accordance with the doctrine of projections as we have expounded, it all corresponding points in the two plans should be so joined, but it is not found necessary in practice to do so, as all the points projected belong to some well-defined series, and can, therefore, be easily distinguished.

The operation of *fairing* the body consists in adjusting the shapes of all these projections, so that the relations between the distances which we have pointed out may hold throughout the ship. When this is the case, the drawing on the paper or on the floor is said to be *faired*.

* The blocks having been separated since the above was written, the four dotted lines in the sheer plan and half-breadth plan do not meet as they should. They must be supposed to meet.

THE ARMSTRONG GUN.

THE Government are exercising unwonted care in keeping the nature of Mr. Armstrong's gun a secret. They have suppressed his application for a patent, and are about to bring a Bill into Parliament to justify that proceeding, the Patent Law Amendment Act of 1852 making no provision for it. If we believed it possible for them to prevent foreign governments from learning all about it we would support them in their course, and would willingly refrain from divulging what we know respecting it. But that is not possible. There is always plenty of French and Russian money to be had in this country for secrets of far less importance than this; and, if there were not, we know perfectly well that our own Governments often make great pretences of secresy to the British public, but at the same time are as communicative to foreigners as they can desire. Knowing these things, we view all official attempts to suppress information in this country as a challenge to the press; and we feel some pride now, as on all other such occasions, in showing that the British press can do as much for the British public, in the way of obtaining information, as bribery can do for foreigners. It was publicly stated last week, by a newspaper correspondent, that the secret of this gun is out, and has been for weeks. But we have as yet met with no public detailed description of the Armstrong gun; and if the writer himself had been in possession of it, he would not, we presume, have evaded it altogether. Judging from the refusals we have ourselves met with, we believe no unofficial person will have had easy access to the information in question. There are, however, means of penetrating all such barriers as a Government like ours can raise; and the following statement will show that the precautions taken in this case have proved insufficient. Before referring to our engravings of the gun, we will endeavour to give an intelligible verbal description of it. Instead of being cast like ordinary cannon—or formed of several longitudinal pieces like the Whitworth cannon—or of a hooped or wire-bound tube as proposed by Captain Blakely, Mr. Mallet, and others—the new gun is formed of an internal steel tube, bound over with strips of rolled iron laid on spirally, somewhat after the fashion of small-arm barrels, the alternate strips being laid in opposite directions, so that the joints may cross each other; or, in other words, so as to "break joint." This system of construction is of course expensive, but it gives great strength with a very small quantity of metal. The internal steel tube is rifled in a very peculiar manner. Instead of having two, three, or four grooves, like ordinary rifled guns—or being formed with an oval bore like that employed by Mr. Lancaster—or with a polygonal bore, as in the Whitworth system—it has a very large number of small grooves close to each other—no less than forty, we believe, in a gun of 2½ inches bore. The shot or shell Mr. Armstrong usually makes of cast iron, of about three diameters in length, and covers it entirely over with thin lead, so that it may readily conform itself to the rifled interior of the bore when forced forward by the explosion of the charge. Provision for loading the gun at the breech is made by cutting a slot near the breech end, down from the upper side into the bore, of a sufficient length to admit the elongated projectile and the charge of powder, and of a breadth slightly greater than the diameter of the bore. The bore itself is also slightly enlarged where it opens into the space formed by cutting out the slot, in order that the projectile and powder, after being lowered into the slot, may be easily pressed forward by hand or other means into the bore. In order to close the space formed by the slot, after the gun is charged, a moveable breech-piece is formed to fit into it, and is furnished with two handles, by means of which it may be lifted out and dropped into its place as required. This breech-piece has fitted to its front face a facet of copper, a portion of which projects slightly, so as to form a dis-

THE ARMSTRONG GUN.

FIG. 1.

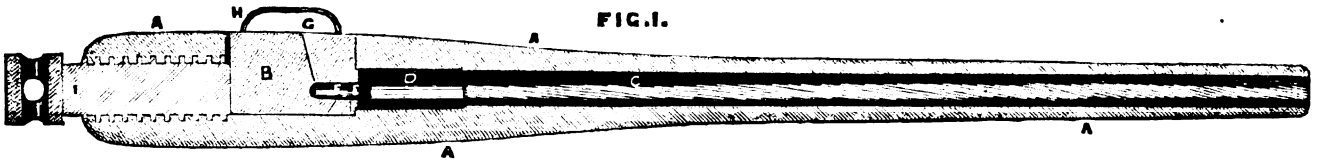

FIG. 2.

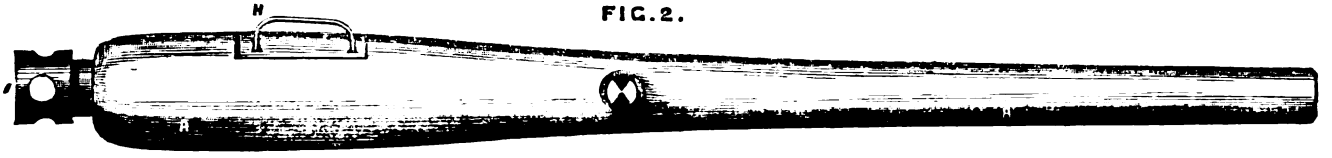

FIG. 3.

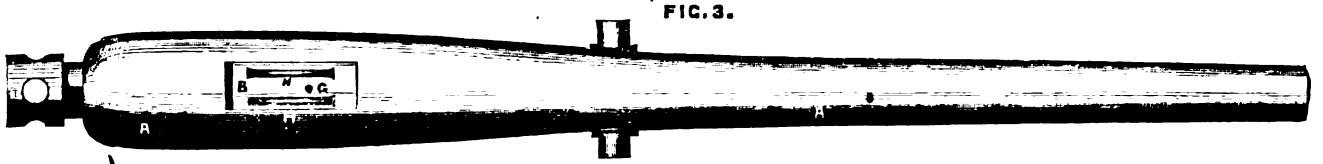

which, when the breech-piece is forced a little forward, will enter the bore behind the charge, and by its expansion at the moment of explosion prevent all escape of gas. The slight forcing forward of the breech-piece is effected by means of a strong screw passing in through the extreme breech end of the gun, and pressing against the rear end of the breech-piece. This screw is turned by a hand lever. The fore end of the breech-piece is bored out at the centre, the bore extending through the copper disc, and into this bore is placed, at the time of loading, a small discharging cartridge. The "touch-hole," or hole for the detonating plug, is formed in the breech-piece, passing down from its upper side into its bore; so that when the piece is to be discharged the detonating cap or plug is struck, the small discharging cartridge is thereby fired, and its fire is instantaneously communicated to the main cartridge in the bore of the gun itself. With his shells Mr. Armstrong uses a percussion fuze of his invention, for causing the shell to burst on striking an object, in case the striking takes place before the time-fuze has operated. This percussion fuze has been already described in our pages, but may fitly be again referred to here. In a cylindrical case within the shell Mr. Armstrong fixes a weight or striker, by means of a pin passing through it and the sides of the case. This pin is cut or broken by the shock which the projectile receives in the gun at the instant of firing, and the striker, being thus liberated, recedes to the rear end of the case, and there remains until the velocity of the shell is checked by coming into contact with some object. When this takes place, the striker, not participating in the retardation of the shell, advances in the case, and causes a patch of detonating composition to be carried suddenly against a fixed point, which fires the composition, and ignites the bursting charge in the shell.

Let us now glance at some of the effects which the introduction of the Armstrong gun is likely to produce. And as the advantages which a light long-range gun must possess as a military weapon will be pretty evident to every one, let us regard it more particularly in its relations to naval warfare. Experiments have already shown that a 32-pounder gun, constructed upon Mr. Armstrong's system, has a greater range, and fires with greater accuracy than any gun at present in use in the navy; and yet, while the former weighs but 26 cwt., the present 68-pounder weighs no less than 95 cwt. We may therefore at once reduce the weight of our naval guns by nearly three-fourths without impairing their range or aim. This would enormously increase the facility of handling them, and therefore leave us free to greatly reduce the number of men employed to work them. Again, with the breech-loading arm, it would probably be found possible to get rid of the running out and in of the gun while in action, by counteracting the recoil in some suitable way; and for this reason also the number of men required to work them might be very much below the present staff. Again, both the bore and the thickness of metal of the gun being greatly reduced, the external diameter of the gun will be so small that very small ports only would be necessary, and this would add materially to the safety of the gunners, especially in close action. Another advantage might be gained in the use of certain guns, particularly the bow-chase guns, on board ship. It is always a matter of great difficulty to give such a form to the ship that the muzzles of these may, when the guns are run out, project sufficiently far to carry the fire of the explosion clear of the vessel. With the long, slight Armstrong gun this difficulty would not be experienced. But, on the other hand, the Armstrong shell is not to be compared, for destructive effect, with the round shells now used in the navy. The charge of powder which it contains is far too small for this. Nor does the Armstrong projectile penetrate thick iron plates, as some suppose. It is found to have but little effect upon them, and this is probably one reason why both the French and English Governments are just now so anxious for the construction of iron-plated ships of war, if such can be successfully devised. That the Admiralty have the means of penetrating iron plates we are prepared confidently to state; but the Armstrong gun is not the gun they would use for the purpose.

And before we conclude we would explain that there is no magic about the peculiar combination of parts which we have explained in describing the gun. The success of the gun depends solely upon the efficient manner in which the projectile is caused to fill and fit the bore of the piece. This accuracy can never be obtained in muzzle-loading cannon. With breech-loaders, however, it is not difficult to secure. Any well-constructed breech-loading cannon would give good results; although Mr. Armstrong's lead-coated projectile has undoubtedly great advantages. Whether the contact of the two metals will deteriorate the projectiles if kept in store long has yet to be seen.

As for the Napoleon field-piece, of which the Emperor has 200 already completed for the Imperial Guard, we do not believe it will at all approach the Armstrong piece in merit of any kind. It is merely a two-grooved, 4-pounder-bore piece, with round shell made to fit the grooves.

We have not succeeded in obtaining exact drawings of any of Mr. Armstrong's guns; but in order to facilitate the comprehension of our description we have drawn out a rough representation of a gun constructed in the manner already explained. Fig. 1 is a vertical longitudinal section; Fig. 2 a side elevation; and Fig. 3 a plan. *A* is the gun itself, formed of a steel tube covered with ribbons of iron, as before described; *B* is the moveable breech-piece; *C* the rifled bore; *D* the enlarged portion of the same; *E* the copper plate on the front of the breech-piece *B*; *F* the bore of the breech-piece *B*; *G* the touch-hole; *H* the handles; and *I* the screw for forcing the breech-piece home. It must be understood that the figures are not engraved to any scale, nor has any attempt been made to give to the parts their exact relative proportions; our only object in giving the figures being to convey a more ready and definite sense of the new weapon than a verbal description alone can give.

NEW TELEGRAPH CABLES.

FIG. 2.

FIG. 3.

FIG. 1.

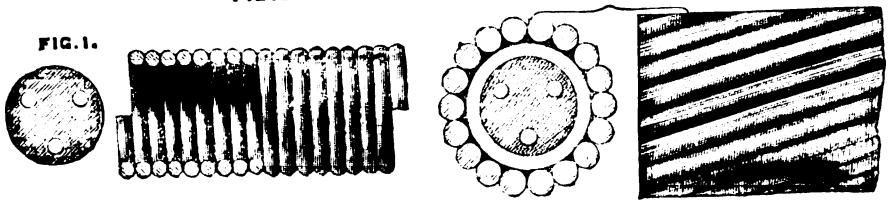

FIG. 4.

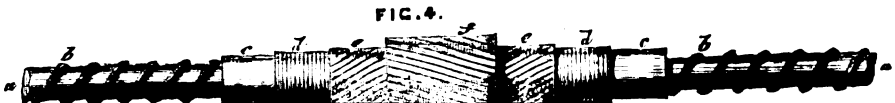

INGENIOUS men are still active in devising means for remedying the known defects of submarine electric telegraph cables. We have two new cables to lay before our readers this week.

The first is the invention of Mr. J. Walker, of the City-road, a very skilful engineer. The prime object of his improvements is to protect the insulated wires and the insulating material from compression by strains of any kind; and this he does by surrounding them with a flexible tube

Digitized by Google

composed of wound wire. The manner in which he prefers to manufacture his telegraph cables is as follows:—He takes, say three copper conducting wires, and covers each wire separately with sheet caoutchouc, having finely-powdered glass on the surface, which is rolled against the wire; and he then applies coats of caoutchouc, either alone or stiffened with pulverised charcoal or fine glass, or he applies gutta percha over all the wires prepared as described, so as to unite them as shown in the transverse section, Fig. 1. Round these insulated wires he winds or coils iron, or other metal wire, so as to form a complete tube, as shown (partly in section) in Fig. 2. For many purposes a cable thus formed will be sufficient; but where great strength is required to prevent longitudinal extension, then he covers the flexible wire tube with strands of iron or steel wires laid spirally as in the section and elevation, Fig. 3, or with iron wires also laid spirally, or with a tube of some fibrous material made in a braiding machine, and protected by a tube of caoutchouc or gutta percha.

The next cable is the invention of Mr. C. Llewellyn Light, also a skillful engineer. The object of the first part of his invention is to enable the conducting wires of electric telegraph ropes or cables to yield without injury to any strain which the outer protecting wires may be capable of resisting, and the objects of the second part are to prevent the outer protecting wires from tending to unwind, and to increase the strength of the rope or cable. His invention consists, first, in winding the copper or other conducting wires of electric telegraph ropes or cables round a central core of gutta percha or other suitable material; and, secondly, in winding the outer protecting wires or strands of any suitable protecting material of such ropes or cables in two layers or sets, one layer or set being laid in a direction contrary to that of the other.

Fig. 4 illustrates this invention; *a* is a central core of gutta percha; *b b* are the conducting wires; *c* is a layer of insulating material covering the conducting wires; *d* is a casing or covering of tarred hemp or other like suitable material; *e* is a layer of wire covering the tarred hemp, and *f* is a second layer of wire running in the reverse direction to the first layer. The drawing shows two conducting wires, but there may be one, two, three, or more, all laid in a similar manner over and round a central core.

THE LATE DR. INMAN.

THE Rev. James Inman, D.D., many years Professor of Mathematics at the Royal Naval College, Portsmouth Dockyard, died on the 7th ult., aged 83. He was the oldest of Cambridge senior wranglers, and has long possessed a just celebrity in naval circles for his application of science to navigation and shipbuilding. He laboured very many years unobtrusively but zealously in his country's service. His degree dates as far back as 1800. He sailed round the world with Flinders, as astronomer, was wrecked with him, and took part with the late Sir John Franklin in that celebrated action in which a fleet of British merchantmen beat off the French Admiral Linois. While Professor of Mathematics at the Royal Naval College he reduced to system the previous ill-arranged methods of navigation, and published several valuable works now in general use in the naval service; but he was best known by his having been the first person in this country who built ships on scientific principles, and by his having educated a class of men by whose hands the "reconstruction" of the British navy *has been* effected. Dr. Inman's translation of *Chapman*, with his valuable annotations, is the text book on which subsequent writers on naval architecture have chiefly proceeded. His pupils, a long list of distinguished naval officers, will long remember him as a type of the high-minded truthful son of science, and the loyal, laborious, unobtrusive public servant. A high tribute to his abilities and worth was paid a few years since, in the MECHANICS' MAGAZINE, by the Rev. J. Woolley, LL.D., late Principal of the Training College for Naval Architects at Portsmouth—the worthy successor, in this office, of the deceased.

PATENT LAW REFORM.

National Patent Law Amendment Committee Room, (Holborn) Black Bull Hotel, Feb. 16th.

GENTLEMEN,—My attention has been directed to your Journal of the 5th inst., in which are some remarks that may be considered as intended to apply to the National Patent Law Amendment Association, of which I am secretary, and one of the original founders. This Association is not a new one, having been founded since 1850, and held many large and influential meetings prior to the Great Exhibition presided over by members of Parliament, &c., and, by frequent and influential deputations to the Government, assisted in carrying most of the important and beneficial changes embodied in the Act of 1852, as I can point out to you in our original prospectus and reports.

It is quite true a well-known patent agent has for a long time been one of its most prominent members, but allow me to state that he has never held any other office than that of patent law adviser, and that he was invited to join the association by a large committee who were all strangers to him, on account of his long and consistent advocacy of patent-law reform.

Asking that the usual courtesy of inserting this in your next number may be accorded,—I have the honour to be, your obedient servant,

JOHN D MAHON, Corresponding Secretary.

[With the above letter—which all persons having any intimate knowledge of patent affairs will know how to value—we have received a circular, the special object of which appears to be the solicitation of subscriptions. This circular contains a list of gentlemen who have allowed their names to appear in connection with Mr. Mahon's "N. P. L. A and I. P. R. Association," but we do not observe among them any of remarkable significance. There is a Mr. Cadby, and a Mr. Button, and a Mr. Sparkhall, and a Mr. Freebody, and a Mr Hussey, and a Mr. Savage—all doubtless gentlemen of eminent influence *among themselves*, but not known to us, nor, we presume, to the Lord Chancellor, or to Her Majesty's Law Officers, or anyone else whom it is absolutely necessary to influence before any Patent Law Reform is obtained. It is true that the names of General Evans, Sir John Shelley, Alderman Sydney, and Mr. Thomas Duncombe, appear prominently as Honorary Members of the Council; but it is not difficult to explain this fact when it is remembered that these gentlemen, although excellent men in their own spheres, are more likely than most men to know nothing whatever about the Patent Laws. But we have no desire to gratify anyone by discussing the pretensions of the Association in defence of which Mr. Mahon writes. If that long-named body be not the mere *alter ego* of a self-seeking individual or two, there is no need for considering that our remarks were "intended to apply" to it. But as Mr. Mahon has chosen publicly to suggest that application, we must refuse to aid him in repudiating it. It has not, however, been made by us.—EDS. M.M.]

TELEGRAPHIC CABLES.

MR WALTER HALL, part-proprietor of the India-rubber works, Southwark, requests us to publish the following remarks:—"I am inclined to think that some of your correspondents are making some grave errors as to the construction of telegraph cables in general. In the first place, I beg to state that I have had about 25 years' experience in the manufacture of India-rubber, including that of gutta percha. I flatter myself, therefore, I have some practical knowledge of the above materials, upon which I beg to make a few remarks. Mr. Hearder says that gutta percha has a tendency to "*retain the electric charge*;" it is my firm opinion that this is in consequence of the *natural* impurities of gutta percha, in the shape of sand and such like ingredients, which cannot be removed by any mechanical means or otherwise. I maintain, therefore, that India-rubber used in its *proper form* is the BEST insulating material for submarine purposes; in fact, for insulating telegraphic wires in general. I stated a few weeks back, that a cable should be constructed in such a manner as to take all strain off the conducting wire or wires, and I am happy to find Mr. Hearder confirms my opinion upon this particular point, which I so strongly advocated at that time. I am also of opinion that all submarine cables should have only one conducting wire, the same as used in the Atlantic cable; samples of cable that I have in my possession fully confirms me upon this point, for cables made with three or more wires are only suitable for laying on sand, or in a horizontal position; as it is quite certain when a cable of this description is bent in any form whatever, that some of the wires have a tendency to stretch, while the other wires are being forced into the insulating material, which would ultimately break all the wires, more especially if gutta percha is used for insulation. A "Telegraphic Engineer" says, "I cannot think the present form of the existing cable can be improved with any advantages;" this I impute to a want of mechanical knowledge on his part, as to the construction of submarine cables; at any rate, time will prove whether a cable can be constructed to suit all the purposes required. I am of opinion the time is not far distant when such will be the case. It is my firm opinion that Mr. Allan's cable will never answer the purpose for which it is intended, as the construction is not in accordance with the strain it will be subject to; therefore, I consider it will be perfectly useless when it is laid, and I have no doubt it would share the same fate as the Atlantic cable."—Would it not have been well for Mr. Hall to have given some *definite* reasons for his condemnation of the Allan cable, and for his prophecy of evil?

THE RAILWAY WORK OF THE SESSION.

IT appears from an official report issued by the Board of Trade that 192 railway and canal bills are now before Parliament. Of this number 129 bills authorise new works. In England 61 bills have been introduced by new companies seeking powers to construct 638 miles of railway; in Scotland five bills, referring to 53 miles, are brought forward by new companies; and in Ireland four bills, referring to 77 miles are introduced in a similar manner. As regards the movements of existing companies, they have introduced 43 bills for 154 miles of new line in England, six bill, for 78 miles of new line in Scotland, and ten bills for 129 miles of new line in Ireland. The total length of new line proposed is, therefore, 1,129 miles, and there are besides 95 miles of deviation lines, and twelve projects for the enlargement of stations.

NEW DOCK AT PORT LOUIS, MAURITIUS.

(Extract from "The Overland Commercial Gazette," Port Louis, Mauritius, 27th December, 1858.)

WE have much satisfaction in announcing that, to facilitate the recently-established mail service between this port, Australia, and the mother-country, the Mauritius Dock Company have commenced the excavations for a vast dry dock, to afford every facility for repairing such noble vessels as we shall shortly have calling at our port (Port Louis). The size of the dock is to be 350 feet long; 80 extreme breadth; 60 mean, and 40 minimum breadth; depth, 23 feet: in fact, capable of easily taking in such magnificent vessels as the *Duke of Wellington*, of 3,755 tons; length, 278 ft.; length of keel, for tonnage, 202 ft.; depth of hold, 24 ft.; breadth, 62 ft. Her Majesty's steam-frigate *Mersey*, length, 366½ ft.; length of keel for tonnage, 254 ft.; breadth, 52 ft.; burthen, 3,726 tons. Her Majesty's ship *Boscawen*, which was lately here, is 2,212 tons; length, 213 feet. Such a vessel would appear like a long-boat in the new dock. The most important fact is, that merchant ships of all sizes can be taken into dock and immediately repaired.

The pumping machinery is being constructed by Messrs Gwynne and Co., engineers, London, whose names stand so favourably before the public. Engines of 100 horse-power will work three centrifugal pumps, each discharging 12,000 gallons of water per minute; and the dock when full, containing 13,000 tons of water, will be entirely emptied in 2½ hours. Besides these pumps, a smaller one, worked by a separate engine, will keep the dock dry during repairs to vessels. The Company have, in addition, a forge, and every appliance for the repairs of iron vessels—this fact cannot possibly be too widely known.

The contractors have engaged to finish the excavations in a year, but nine months will probably suffice for the reception of vessels.

THE ADMIRALTY TABLES.

DURING the passage through the press of the Admiralty Tables published in our Supplement of last week, the small and fine figure type representing the fraction $\frac{3}{4}$, became damaged in two or three places. The defect was remedied as soon as discovered, so that a small portion only of our issue appeared without the fraction mentioned in its proper place above the word "Displacement," —sometimes written "Dispt." Wherever this word appears (either in its full or in its contracted form) in the headings on pages ix., xiii., and xv., the fraction $\frac{3}{4}$ should appear above it on the right (thus, Dispt.$^{3}/_{4}$), meaning the cube root of the square of the displacement.

THE ROYAL MINT.

AN unexampled amount of activity, we are told, exists at the Mint, in consequence of the great demand for silver coin. Seven presses are constantly engaged in stamping, and they throw off nearly a million of pieces per week. Foreign mints are as busily employed in the creation of small monies, whilst the mints of Bombay, Bengal, and Madras are being enlarged to double their original sizes, in order to meet the strain which is likely, under the new organisation of things in those presidencies, to come upon them. The enlarged Calcutta Mint will boast twenty-four coining presses—three times as many as the Royal Mint possesses—and will be capable of producing 600,000 coins per day! This may give some faint notion of the gigantic scale upon which things must be arranged to meet the requirements of the Indian Empire.

PATENT COUCHES, &c., FOR INDIA.

MOHAH RAJAH, of Burdwan, one of the wealthiest Princes of India, whose adherence to British rule during the late rebellion was so conspicuous for its unqualified loyalty and active co-operation, has showed his faith in our prolonged supremacy in a very simple, although unintentional manner. He gave orders somewhat extensively and liberally to several of the English manufacturers, and amongst them, he entrusted his body's repose—for with all his treasures he possesses not an immunity from "the ills which flesh is heir to"—to the consideration and skill of Mr. Alderman, of Soho Square, who has just shipped for India some very ingeniously-constructed couches and chairs to be carried by attendants and others, of the latter, for perambulatory purposes. The couches are patented, and singular and pre-eminent as works combining varied mechanical resources. For instance, a child can noiselessly elevate and depress a patient to any and every position the recumbent is capable of assuming. All this is done without touching the invalid, whose glance may be all the while resting upon a book, a desk being so arranged as to keep one unvarying inclination to the eyes of the reader. The mattresses of these couches are likewise worthy of especial mention, as they possess the capabilities of a free ventilation and a perfect elasticity. Herein the physician will at once recognise excellences of the highest order, as the absence of any solid pressure places the creation of "bed sores" upon the uttermost verge of possibility.

FRENCH FLOATING BATTERIES.—"The intended transformation of the steam line-of-battle ship *Jemmappes* into a floating battery is," says a letter from Toulon, "the commencement of a new and important application of the system of floating-batteries. The French Government has it in contemplation to fit out several of these steam fortresses, destined for the defence of the different naval ports, which they will shelter from all aggression. These enormous naval constructions will be, like the floating batteries which were used with such formidable effect against the fort of Kinburn, covered with a sheathing of wrought iron."

NOTICES.

The demand for Mr. E. J. Reed's paper on the Ships of the Royal Navy has been so great that the Journal of the Society of Arts, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 6 o'clock on Thursday evening each week. None can be received after 5 o'clock on Thursday evening for the ensuing number.

CORRESPONDENTS' QUERIES.

GENTLEMEN,—The writer would be glad to receive information on the following points, or to be informed where he may obtain it. 1st. What are the advantages to be obtained by rotary steam-engines? 2nd. What has proved the hindrance to their introduction? 3rd. What is the best rotary engine which has been made? 4th. What is the best treatise on the subject? C. P.

January 18, 1859.

GENTLEMEN,—I should be glad to learn of a rule to discover the quantity of air passing through a pipe of a given size per minute, the fanners making a certain number of revolutions per minute. C. G. P.

18 Kingston Place, Glasgow, Feb. 11, 1859.

GENTLEMEN,—Wishing to pass for a Chief Engineer on board one of Her Majesty's Ships, I shall be glad to learn from any of your correspondents what examinations, &c., are required. G. HOGBEN.

CORRESPONDENT'S REPLY.

ELECTRO-MAGNETISM.

GENTLEMEN,—I think I can answer the very important question of your correspondent, T. C. H. The phenomenon which he observed is not new, although it is perhaps a novelty in its connection with the induction-coil, and may lead to a considerable augmentation of power in that very interesting apparatus. If T. C. H. has access to the *Cosmos*, edited by the Abbé Moigno, he will find, in vol. xi., p. 71 (July 1857), the following passage:—"M. du Moncel adresse de son chateau de Libesey, des experiences destinées à mettre en évidence les propriétés et les avantages des electro-aimants en fer à cheval, dont une seule branche est entourée d'une helice magnétisante, et qu'en raison de cette dissymétrie il appelle *électro-aimants boiteaux*. (Lame electro-magnets.) Ces electro-aimants sont remarquables à ce point de vue que leur puissance attractive, sous certaines conditions, est tres peu inferieur à celle des electro-aimants de même forme et de meme volume, armés sur leurs deux branches de bobines ou hélices magnétisantes." And in the same volume, pp. 215-16, M. Nickles shows that the fact claimed by M. du Moncel as a discovery has been long known—namely, that the attractive power of an electro-magnet is increased by extending (within certain limits) the length of the core. Now, this was precisely the effect produced when T. C. H. touched the top of the core with a pair of pliers or any other piece of iron. It became more powerfully electro-magnetic under the influence of the current, and hence the accelerated vibration of the hammer. I should be glad if T. C. H. would try an extended core of different lengths, and communicate the result through the columns of the MECHANICS' MAGAZINE. GEORGE BLAIR.

Glasgow, Feb. 19, 1859.

P.S.—DuMoncel states that he found the energy of the helix-covered leg of his *electro-aimant boiteux*—or, in other words, that of a straight electro-magnet like the core of T. C. H.'s induction-coil (including its primary wire)—greatly increased when he merely approached the naked leg and cross-piece to that end of the covered bar which did not act upon the armature. Perhaps T. C. H. will verify this result by bringing a piece of soft iron near to, but not into absolute contact with the upper end of his core. I should say, also, that with a *single* cell of Callan's battery he will find the effect which he observed less visible, because with two or three cells there is a surplus of intensity in the current, which is capable of saturating with magnetism a larger and longer core than that of his instrument. It would be interesting if, in stating the effects produced, he would specify the exact dimensions of his apparatus—especially the length and diameter of the core or cores, and the size of the elements of his battery. I have one or two induction-coils, but they are not fitted by their form for these experiments, which may lead to useful results. G. B.

CURRENT EVENTS

IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

[COMPILED BY OUR OWN CORRESPONDENT.]

The Shipowners' Movement—Petition against the Timber Dues—Dock and River Interests at Sunderland—Explosion on Shipboard—Petition against proposed Railway at Liverpool—Increased Protection to "Registrations"—Bootmakers and Machinery—Drinking Fountains—Stained Glass Window—Ventilating Ships—Colliery Furnace Regulator—New Mechanics' Institute—Nineveh Marble for Newcastle—Engines and Carriages for the Egyptian Viceroy—The Largest Hammer in England—Factories in the Midlands—Proposed Extension of the Factories Act—Steam Boiler Explosions—Commencement of the Eden Valley Railway—Collision of Steamers in the North Sea.

A SHIPOWNERS' grievance meeting has been held at Newcastle-upon-Tyne, presided over by the Mayor. The shipowners of the Tyne were urged to unite with those of other ports in seeking to obtain from Government and the country something like a practical acknowledgment of their just position, by the removal of those burdens. Resolutions were unanimously adopted, calling for a repeal of the timber duty, and the abolition of the light dues, passing tolls, and other unfair imposts and restrictions; a petition to Parliament, based on these demands, being also agreed to.——The Sunderland Town Council have agreed, without discussion, that the Corporation seal should be attached to a petition against the timber dues.——A great effort is being made in Sunderland to secure the amalgamation of the dock and river interests.——From an unknown cause a ship laden with coals has exploded at the South Dock, Sunderland.——The Toxteth Board of Health have adopted a petition against the bill by which it is proposed to connect Liverpool with Garston by railway, and thus, *viâ* the Great Northern, afford another railway route to London. This route is at present considerably used, but passengers now have to travel by omnibus from Liverpool to Garston, a distance of seven miles.——The Birmingham manufacturers propose to secure protection for six years instead of three, under the Registration of Designs Act, to articles in metal; articles of minor importance paying a smaller fee for registration to retain the present term of three years.——Messrs. Boote, of Burslem, are using a new machine process for making tesselated tiles, whereby it is said that tiles of "an excellent quality and tasteful design" can be produced at little more than half the cost necessitated by the former process.——The bootmakers of Stafford have met, 2,000 strong, to hear deputations from Northampton, and with much enthusiasm have passed the following resolution in particular:—"That inasmuch as the manufacturers of Stafford have entered into a combination with the manufacturers of Northampton for the purpose of forcing the machines on the people of both towns, we, the people of Stafford, feel called upon in self-defence to unite with the men of Northampton to resist it in every way in our power."——Alderman George Higginbottom gives four drinking fountains to the town of Ashton-under-Lyne, and the corporation engages to supply them with water.——A second stained-glass window has been placed in the south chancel of Manchester cathedral, both being given "to the honour and glory of God, by a citizen of Manchester, once a chorister in this church."——Mr. Jordan, shipbuilder, of Liverpool, has invented a means of ventilating ships by the use of hollow iron masts, which collect the foul air at their base, and discharge it into the general atmosphere through various perforations near the summit. Models illustrative of this invention have been exhibited in Liverpool.——Mr. Burton, the underviewer of the Springwell colliery, Staveley Works, Derbyshire, has arranged a simple apparatus, worked by a small feeder of water, called a "furnace regulator," by which constant attention to the ventilating furnace in a pit is secured. Since its first use the ventilation of the pit has been increased 30 per cent. if kept constant. The "regulator" has been introduced into the South Yorkshire colliery, Barnsley.——The new building for the Mechanics' Institute at South Shields is about to be commenced. The committee have accepted the plans of Mr. Wardle, to embrace a hall for 1,000 people; a library room, a news room, 4 class rooms, a museum, a kitchen and kitchen range, and apartments for librarian.——Four Nineveh marbles, weighing together seven tons, have arrived at the Literary and Philosophical Institute at Newcastle-upon-Tyne. They are the gift of Mr. W. K. Loftus, who is intimately associated with that town, and a recent explorer among the Nineveh remains.——The series of locomotives and carriages to be used by his Highness Said Mahommed, Viceroy of Egypt, in his state excursions on the railway between Alexandria and Cairo, which have for some time been under construction by Messrs. R. Stephenson and Co., of Newcastle, are now nearly completed. The locomotives are two in number. One is an enormous military engine which may be worked up to a thousand horse power; while the other, though a small one, and quite a toy compared to the other, is of an entirely novel construction, owing to its being a locomotive and carriage combined, so that the Viceroy may occasionally take his place as amateur engineer. These elegant and noble specimens of engineering art and of British manufacture, have been finished and ornamented in the highest style of Oriental splendour and magnificence.——There has been sent from the works of Messrs. R. Morrison and Co., of Newcastle-on-Tyne, the largest steam hammer in England. It is for the Mersey Steel and Forge Company, Liverpool. The total height is 21 feet, and the width between the frames 14ft. 6in. The hammer bar is 15 inches diameter, and 19 feet long, and is made of steel, with the piston, which is 36 inches diameter, forged in one solid piece—the hammer bar forming a solid mass of steel, weighing above 7 tons in the finished state, with a stroke or clear fall of 6 feet. The cylinder is 36 inches diameter, and weighs, finished, above 8 tons; the two frames weigh 15 tons. The hammer, when in its place, will stand upon an anvil

Digitized by Google

mass of cast-iron, wood, and stone, 32 feet long, 18 feet wide, and 9 feet deep. It is intended for preparing the steel for being rolled into plates, which are now much used for shipbuilding and other purposes.——The report for the half-year ending with October of Mr. Baker, the new inspector of factories for the Midlands, states that the 30 per cent. of the year's accidents arose from unfenced gearing wheels; 43 per cent. arose from carlessness on the part of the sufferers or their fellows; and 18 per cent. were unavoidable. Prominent mention is made of "an outrage committed by the refusal of the millowner to pay the injured person's wages during his absence for cure," in a case which did not involve carelessness.——On Thursday Mr. Crook, M.P., will move to introduce a Bill, to place the employment of women, young persons, and children in bleaching and dyeing works, under the Factories Act.——At the monthly meeting in Manchester, on Tuesday, of the Association for the Prevention of Steam Boiler Explosions, the chief inspector reported:—"We have at this date 480 mills and other works and 1,327 boilers under inspection. Since the 28th ultimo we have visited 177 members, and examined 427 boilers and 371 engines. The number of boilers found defective were 114, and 13 dangerous. 12 boilers were also without blow-off cocks, eight without glass gauges, and eight fusible plugs were inoperative from being placed on the wrong place, one from being coated with hard scale."——A colliery engine boiler at Willenhall, near Wolverhampton, blew up on Saturday last. Some old and worn plates were to have been soon replaced. One person slightly injured.——Mr. Torton, the contractor for the Eden Valley Railway, has made a commencement with the works at the Julian Bower Farm, Whinfell.——The steamers *Lapwing* and *Isleman* have came into collision off the Mull of Kintyre. The *Lapwing* sank within four minutes, taking down with her a woman and a boy. The *Isleman*, though much injured, escaped by having extra water-tight compartments.

NOTES FROM THE SOUTH WEST.

[FROM OUR OWN CORRESPONDENT.]

Foreign Trade of the Port of Plymouth—New Line of Telegraph from Salisbury to Exeter—The Committee on Dockyard Economy—South Wales Railway Rails—The Narrow Guage—Private Telegraphs—Mr. Mechi in Devonshire—New Works—Death of Mr. Stutchbury—Bristol and Forest of Dean Coal Company—Departure of Workmen for the Nicaraguan Railway—Southampton Docks—Lights at Sea: Carelessness shown on the Subject—Lowering Ships' Boats in Rough Weather—Appointments—Landslip at Polruan—Town Mortality—Conversion of Ships of War into Screw-steamers.

THE foreign trade of the port of Plymouth increased satisfactorily in 1858 over the previous year.——The Electric Telegraph Company have resolved to erect a new line of telegraph from Salisbury to Exeter, *viâ* Yeovil.——The committee appointed to consider the question of dockyard economy has completed its labours. All the naval establishments—Pembroke, Plymouth, Portsmouth, Devonport, Sheerness, Chatham, Woolwich, and Deptford—have been visited in succession.——At the half-yearly meeting of the South Wales Railway Company, on Friday, it was stated that £5,000 had been expended in replacing the Barlow rails for seven miles to the west of Loughor. As the Barlow rails wear out, they are being replaced with bridge rails.——Messrs. W. D. and H. O. Wells, tobacconists and snuff-manufacturers, of Bristol, have laid down telegraphic wires between their warehouses in Maryport-street and their manufactory in Redcliff-street. The wires were laid under the direction of Mr. J. R. Saunders, telegraphic engineer and contractor. In the course of a lecture delivered in the town, a day or two since, it was stated that the Bristol Gas Company had also connected their depôts by means of a private telegraph, and that Messrs. Waterlow, the metropolitan law-stationers, had established telegraphic communication between their various departments.——Mr. Mechi, of Tiptree Hall fame, has been visiting Earl Fortescue at Castle Hill, Devonshire, for the purpose of inspecting his lordship's agricultural operations in that locality.——The death is announced at Bristol of Mr. S. Stutchbury, curator of the local Philosophical Institution. The deceased, who was born in London in 1798, was in 1825 appointed naturalist of an expedition fitted out by the Pacific Pearl Fishery Company to New South Wales and the Polynesian Isles. This expedition occupied several years, and on his return to England Mr. Stutchbury was appointed curator of the Bristol Philosophical Institution. He afterwards went out as geological and mineral surveyor to the colony of New South Wales, returning to England two and a-half years since. Mr. Stutchbury was a member of the Geological, Linnæan, and several other societies.——The prospects of the Bristol and Forest of Dean Coal Company are stated to have considerably improved, in consequence of recent success in winning the Yorkley seam, a valuable house coal more than three feet thick. A new engine is about to be erected. The seam just won is estimated to contain 500,000 tons of coal, and two other seams are expected to be reached in a few months containing upwards of 2,000,000 tons.——The *Parana* which left Southampton yesterday week with the West India and Pacific mails took out a party of workmen for the Nicaraguan railway.——The north wall of the inner dock, Southampton, has been reconstructed and strengthened, and the works of the inner dock generally are in such a state of forwardness as to lead to the expectation that it may be opened for the reception of vessels in the course of next month. The accident to the north wall has, together with the unsatisfactory state of the grounds on the south side of the dock, induced the engineer, as a matter of precaution, to give greater strength and depth of foundation to the south wall and to adopt other measures in carrying on the works, which have involved some additional expense. The construction also of four new jetties and of two iron caissons to admit, in case of need, of the repair or renewal of the gates without interruption of the working of the inner dock, will involve a further increased outlay. These extra charges will make the cost of the completion of the dock altogether amount to £50,000.——The *Pera*, recently arrived at Southampton, reports having passed off Cape de Gatte a large fleet of vessels, none of which exhibited the regulation lights. This is a point which ought to be looked to. During the *Pera's* homeward voyage, when about 40 miles north of Cape St. Vincent, a French schooner was observed with her colours half-mast high as a signal of distress. With the concurrence of the Admiralty agent the *Pera* bore down to the schooner and a boat was sent in charge of the third officer to see what was wanted. The boat was lowered with six men in her by Captain Guthrie's plan, with ease and safety, although the *Pera* was rolling heavily in a rough sea.——At Lymington a railway pier—constructed so as to admit the passage of a train to the end of it—is now finished.——Mr. Greensell has been appointed harbour master of Lymington for the next seven years.——The Portsmouth commissioners have elected Mr. Pines as their surveyor.——A landslip has taken place in the new building yard of Messrs. N. and J. Butson, at Polruan, in which was a vessel almost complete in frame. The earth fell against the shores supporting the vessel, started her three feet from her original position, and disunited the whole structure. The damage done was consequently serious, but happily no loss of life took place.——A pamphlet has recently been issued by Mr. E. Bishop, M.D., on the "Mortality of Devonport, viewed with reference to the preventible causes of disease." In the course of his pamphlet the doctor says, at the period of the last visitation of cholera there were 276 inmates in the Taunton workhouse, the breathing space in some of the rooms not being more than 68 cubic feet per head, and 60 of the poor people died in less than a week. In the county gaol of the same town, the breathing space allowed to each prisoner ranges from 819 to 925 cubic feet, and while the poor were being destroyed in the workhouse, not a single case of cholera or diarrhœa occurred among the prisoners.——The *Rodney*, 90, is ordered to Chatham for the purpose of being altered to a screw steamer. The *Trafalgar*, 120, which is being converted into a screw steamer (of 90 guns) will be undocked next month. A third vessel, the *Severn*, 50, is also to undergo a transformation of a similar character; and it is stated that she will be cut in two and lengthened, with this object.

NOTES FROM THE EASTERN DISTRICTS.

[FROM OUR OWN CORRESPONDENT.]

Building Operations at Ipswich Borough Gaol—Railway Extension—Terra Cotta Works at Stamford—Colne Valley and Halstead Railway—Lengthening the "Pacific" Steamer—Telegraphic Communication between the North of England and the Continent viâ the Cambridge—Coal for Locomotives—Lynn and Bury St. Edmund's Navigation—Railway Differences in the East—Eastern Counties Railway: Way, Works, and Plant.

A WEEK or two since a little episode in the Ipswich Town Council with reference to the quality of the bricks used in some works in progress at the borough gaol was noticed under this head. Mr. C. Humphreys, surveyor, of 61 Leadenhall Street, has been down to Ipswich, and reported that the materials and workmanship were not such as the corporation surveyor ought in fairness to condemn; but that the contractor (Mr. H. Luff), by reason of the insufficiency of the concrete works, ought to indemnify the council from any loss by failure of works on payment of contract. The council have resolved, after a good deal of discussion, to adopt and act on Mr. Humphrey's report.——The Boston extension of the Sleaford and Midland Counties Railway is expected to be opened throughout in April.——Terra cotta works have been opened at Stamford by Mr. J. M. Blashfield; and it is considered that the establishment may lead to important results, as the district is found to be rich in deposits. The clays are pronounced excellent.——The Colne Valley and Halstead Railway (from Chappel to Blue-bridge) has been formally handed over to the company by the contractor, Mr. Munro, that gentleman having completed the works within twelve months.——The lengthening the *Pacific*, one of the Galway line of steamers, was lately undertaken by Messrs. Samuelson of Hull, and it is stated that the vessel will have to be taken by them to Grimsby, in order to admit of the execution of the work.——The British and Irish Magnetic Telegraph Company are erecting wires from Cambridge to join their lines at Doncaster, with the view of bringing Liverpool, Manchester, Hull, Leeds, Bradford, and other important centres of industry into direct communication with the north of Europe by means of the cable lately submerged from the eastern coast.——The Eastern Counties Railway Company are, it is understood, increasing the consumption of coal in their locomotives, and the furnaces are being slightly altered with a view to the consumption of the smoke. Some of the engines are now run, it is said, for 6d per train mile.——Allusion was made recently in this Magazine to the reopening of the River Lark navigation between Bury St. Edmund's and King's Lynn. The object is now accomplished.——Reference was made recently to the attitude assumed towards the Eastern Counties Railway Company by the subsidiary companies provisionally amalgamated with it—the Norfolk and Eastern Union. The points in dispute are the powers and functions of the joint committee of management, the alleged omission of traffic receipts in the joint half-yearly balance sheets, and deductions alleged to be unduly made from the proportion of nett traffic awarded to the Norfolk and Eastern Union shareholders. These differences are of long standing, having been increasing in magnitude since the provisional amalgamation in 1854, and they have now resulted in a bill in Chancery being filed by the Norfolk and Eastern Union Companies. Of course the end is not yet.——The way and works on the Eastern Counties lines are now officially reported to be greatly improved, all important renewals of bridges having been completed. New plant and carriages have also been provided to some extent, the cost being charged to revenue account.

NOTES FROM SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

Engineering Works in the Glasgow District—New Clipper for the Indian Trade—Gas and Water Supply of St. Petersburg—Scottish Manufactories—The Clyde Trust: Election of Engineer—Proposed Mining School in Glasgow—Grangemouth Railway—New Buildings at Leith—Death of Mr. Cowan—The Pig Iron and Coal Trades—Destructive Fire—Death of Mr. Mackain, C.E.

MESSRS. ROBERT STEELE and Co. have contracted to build an iron screw-steamer, of 2,500 tons (for Messrs. J. and A. Allan, of Glasgow) for the Liverpool and Canadian trade. Messrs. Steele and Co. have also two barges to build for the navigation of the Ganges. The machinery for the new Canadian steamer is to be furnished by Messrs. Macnab and Co., Shaw's Water Foundry. The works lately occupied by Messrs. Scott, Sinclair, and Co., and now by the Greenock Foundry Company have been re-opened. It is stated that contracts for iron shipbuilding have been entered into by Messrs. J. Reid and Co., Port Glasgow, and that Messrs. J. and T. Thomson, of Glasgow, are about to lay down a large steamer for the Mediterranean trade.——On Saturday a handsome clipper ship of 947 tons, intended for the East Indian trade, and built for Mr. J. Kerr, of Greenock, was launched from the yard of Mr. J. M'Millan, of Dumbarton. She is referred to as a fine specimen of marine architecture, and is the fifteenth vessel built for Mr. Kerr at the yard. The clipper, which was named the *Bombay*, is 185 ft. long, 21 ft. 10 in. deep, and 34 ft. 6 in. beam——Mr. R. Laidlaw, of the firm of Messrs. R. Laidlaw and Son, of Glasgow, has just returned from St. Petersburg, having obtained a contract for supplying and erecting the whole of the apparatus and pipes required for the new gas and water works in that city.——Some interesting facts with reference to Scottish manufactories are stated in the 28th half-yearly report of Sir John Kincaid, Government Inspector. It appears that 159 cotton mills were at work in 1835, and employed 32,580 persons, of whom 10,529 were males and 22,051 females. In 1857, the number of mills at work was 152, and 34,698 persons were employed in them, 7,609 being males and 27,089 females. The number of woollen mills at work in 1835 was 90, employing 1,712 males and 1,793 females; in 1857, the number of mills had increased to 196, employing 4,942 males and 4,338 females. In 1835 the number of flax mills was 170, employing 3,392 males and 10,017 females; in 1857, although the number of mills was only 168, the number of persons employed had increased to 8,331 males and 23,391 females. The number of silk mills—six—remained stationary. The increase in the number of persons employed is worthy of note, as the adoption of improved machinery would, it was thought, diminish the demand for manual labour.——The Clyde Trust have come to a decision in regard to the appointment of an engineer to succeed Mr. Ure, who lately transferred his services to the River Tyne Commissioners. Five gentlemen had been selected for the choice of the trustees from a considerable number of applicants: and Mr. Dreghorn proposed that Mr. Ower (who has had the superintendence of harbours and piers at Dundee) should be appointed Mr. Ure's successor. Mr. Allan Gilmour proposed an amendment to the effect that, in the existing state of the works, it was not expedient to appoint a permanent engineer, but that Mr. Duncan—who, for the last nine years, had acted as assistant-engineer to the trust—be appointed engineer *ad interim*, to co-operate with the committee of works at a salary to be agreed upon. Mr. Duncan's salary as assistant-engineer has been £150 per annum, and an advance to £600 was hinted at. Mr. Duncan was elected by 12 to 10——A meeting of gentlemen connected with the coal and iron mining districts of the west of Scotland has adopted resolutions recognising the necessity for a mining school in Glasgow.——The permanent way of the Grangemouth Railway is being laid as fast as possible, and the line is expected to be ready for traffic in April.——Some extensive buildings are in progress at Leith; among them is a steam flour mill (estimated to cost about £20,000) for Messrs. Tod, "presently"—so runs the idiom—of Stockbridge Mills. A large wool store has also been built for Messrs. Adam and Macgregor.——Mr. Alexander Cowan, head of the important firm of Cowan and Co., paper manufacturers, has just died at the patriarchal age of 84.——The pig iron market had on Monday again become dull, and prices were reported the turn lower. Last week's shipments were—foreign 2,268 tons, and coastwise, 4,958 tons; total, 7,226 tons against 10,490 tons in the corresponding week of 1858. Coals have continued dull, both for home use and shipping. No change, however, is reported in prices.——The Glasgow papers report a destructive fire at the establishment of Messrs. Randolph, Elder, and Co., engineers and millwrights, Centre-street, Tradeston. The premises were full of machinery of various kinds.——The death is announced, at Dalmarnock, of Mr. D. Mackain, engineer of the Glasgow Waterworks.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated January 1, 1859.

14. M. Wigzell, of Exeter. An improved form of nail or driving article.

Dated January 5, 1859.

42. W. Corfield, jun., of Charlton-Adam, Somerset. Improvements in chains for coupling, cranes, cables, mining purposes, hoisting, and all other purposes where chains are used.

Dated January 8, 1859.

66. W. Delany, of Chicago, United States. Improvements in submarine boats or vessels, and in apparatus used for

Digitized by Google

working under water. A communication from L. D. Phillips.

70. W. E. Newton, of Chancery-lane. Improvements in steam engines and steam generators. A communication from L. Arnier, of Marseilles.

Dated January 19, 1859.

169. W. Clark, of Chancery-lane. Certain improvements in boots and shoes, and in the machinery, apparatus, and means employed in such manufacture. A communication from C. J. Desnos, of Paris.

Dated January 21, 1859.

196. W. H. Morrison, of Nottingham, Manufacturer, and H. Kinsey, of the same place, Machinist. Improvements in means or apparatus employed in the manufacture of bonnet-fronts, ruches, ribbon trimmings, and other goffered or plated articles.

Dated January, 31, 1859.

273. D. Bentley, of Accrington, Millwright. Improvements in self-acting apparatus, applicable to letter-press printing-machines, for supplying and removing the paper.

275. T. Wilson, of Birmingham, Engineer. Improvements in breech-loading and other fire-arms.

277. H J. Newcombe, of Shenley, Herts. An improved apparatus for heating or warming buildings.

279. A. V. Newton, of Chancery-lane. An improved method of extracting gold and silver from their ores. A communication from L. Solomon.

Dated February 1, 1859.

281. L. Rigolier, Engineer, of Rhône, France. A new brake for railway carriages.

283. S. B. Eveleigh, of Salford, Hat Manufacturer. An improved form or construction of hats or covering for the head.

285. S. Plimsoll, of Hatton-garden, Coal Merchant. Mining apparatus for use in mining coal and other minerals, and also for separating the small coal and crushed ores from the shale, dirt, and other matters with which it may be in combination, and for drying the same.

287. R. Gormully, of Grafton-st., Fitzroy-sq. Improvement of pianofortes with upright frames.

289. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in sewing machines. A communication.

291. M. Loam, of Truro. Improvements in machinery for raising sewage and other waters and matters.

293. M. Henry, of Fleet-st. The manufacture and useful applications of certain bituminous products and compounds of bitumen with other matters, and treating and applying certain natural bitumen or bitumens for such purposes. A communication from Moisant and Co.

295. W. E. Newton, of Chancery-lane. An improved blowing machine. A communication from A. L. H. F. de Sauville, of Paris.

Dated February 2, 1859.

297. E. Wilkins, of Camberwell, Gentleman. Improvements in drain pipes and tiles for draining and liquid manuring land.

299. F. F. Rateau, of Paris, Practical Engineer. An improved steam-engine actuated by regenerated steam.

301. S. Tearne, of Birmingham, Japanner. Improvements in ornamenting surfaces.

303. I. Clements, of Birmingham, Warehouse Clerk. A new or improved method of manufacturing curtain rings.

305. G. Leach, of Leeds, Yarn Spinner. Improvements in dressing yarn or thread in the hank, and in machinery for winding off the same.

Dated February 3, 1859.

307. T. Storer, of Birmingham, Undertaker. A new or improved funeral carriage.

308. J. Woodrow, of Oldham, Hat Manufacturer. Improvements in the manufacture of hats or coverings for the head.

309. W. Clayton and J. Goodfellow, of Blackburn, Engineers. Certain improvements in metallic pistons.

310. H. C. Jennings, of Great Tower-st., Practical Chemist. Improvements in the manufacture of paper and artificial parchment, and of gelatine applicable to the sizing of the same, and other purposes.

311. J. Petrie, jun., of Rochdale, Machinist, and T. Wrigley, of Heap Bridge, Paper Maker. Improvements in machinery or apparatus for washing rags and other materials for the manufacture of paper.

312. S. D. Davison, of Leith, Engineer. Improvements in locomotive steam-engines.

313. A. G. Pooley, of Rotherhithe, Agricultural Chemist. Improvements in preparing fish for manure, and in apparatus for the same.

Dated February 4, 1859.

315. H. Greaves, of Victoria-st., Westminster, Civil Engineer. Improvements in the preparation of iron bars, of the various forms or sections used in the construction of sheet-iron structures, and in machinery employed for the same.

316. W. Thompson, of Paris. An improved printing telegraph.

317. A. Allan, of Perth, Engineer. Improvements in locomotive steam engines, in part applicable for retarding and stopping railway trains.

319. S. L. Trotman, of Liverpool, Merchant. Improvements for the more effectually securing or fastening envelopes or other like receptacles, and the more securely affixing postage-stamps or other adhesive labels.

320. R. A. Brooman, of 166 Fleet-st., London, Editor of the MECHANICS' MAGAZINE and Patent Agent. An improvement in cooling worts and beer. A communication from Madame Jolibois, of Dijon, France.

321. R. A. Brooman, of 166 Fleet-st., London, Editor of the MECHANICS' MAGAZINE and Patent Agent. Improvements in shirts. A communication from L. Levy Neyman, of Paris.

322. G. H. Baylis, of Lambeth, and F. Robinson, of Salisbury-street, Lisson-grove. An improved indicator for registering the withdrawal of liquids from vessels.

323. F. H. Maberly, of Stowmarket, Master of Arts. Improvements in obtaining spring power, and in its application to various purposes.

324. L. Bonneau, of Paris, Civil Engineer. Improvements in apparatus for registering the time carriages are employed in conveying persons from place to place, and also in moving from place to place when unoccupied.

326. P. Adie, of the Strand, Mathematical Instrument Maker. Improvements in apparatus for taking levels and measuring angles.

327. W. R. J. Packer, of Dublin, Dyer. Improvements in the plough or plough-share, for the purpose of more effectually pulverizing, breaking up, or cutting into small particles the earth or sod separated from the ground by the plough-share.

329. A. Barclay, of Kilmarnock, Engineer. Improvements in electric, magnetic or electro-magnetic telegraph ropes or conductors, and in machinery or apparatus to be used on board ship for laying or paying out the same.

Dated February 5, 1859.

331. F. H. Maberly, of Stowmarket, Master of Arts. Improvements in apparatus for corking, for drawing corks, in taps, in the necks of bottles, in the bung-holes of barrels, and in similar articles.

332. N. Greenhalgh, of Bolton, Cotton Spinner, W. Shaw, of the same place, Cotton Spinner, and J. Mallison, jun., of the same place, Yarn Agent. Certain improvements in the treatment and preparation of yarns or threads previously to dyeing.

333. R. Tinker, of Penrith, Cumberland, Churn Maker. Improvements in churns.

334. H. Anderson, of Liverpool, Mechanic. An improved construction of apparatus for winding window blinds, sun shades, and similar articles on their rollers.

335. T. Sykes, of Cleckheaton, York, Manufacturing Chemist, and B. C. Sykes, of the same place, M.D. Improvements in obtaining or separating oily, fatty, greasy, tarry, waxy, and resinous substances, from oleaginous seeds, nuts and fruits, wool, silk, hair, cotton, flax, line, hemp, furs, skins, leather, bones, fish, and other animal matters and refuse, woollen and cotton waste and refuse, also textile fabrics and refuse grease, produced in various branches of industry, indigo, lac, lac dye, and other dyes.

337. M. Booth, of Manchester, Finisher, and J. Farmer, of Salford, Machinist. Improvements in sizing or stiffening woven fabrics.

Dated February 7, 1859.

338. G. F. Chantrell, of Liverpool, Furnace Engineer. Improvements in the treatment of charcoal after its manufacture or revivification.

340. A. Lyons, of Chancery-lane. A pocket protector.

342. M. Curtis, of Manchester, Machinist, and J. Miller, of Staley-bridge, Manager. Improvements in certain mules for spinning cotton and other fibrous substances.

344. T. Sims, of Conduit-st., Regent-st. Improvements in the application of photography to engraving and printing.

346. J. Smith, of Bradford, Machine Maker. Improvements in machinery, or apparatus for preparing and combing wool, and other fibrous substances.

Dated February 8, 1859.

348. T. Moss, of Fleet-st. Improvements in the manufacture of paper and printing ink, suitable for bank-notes, bills of exchange, and other documents requiring like security against being copied.

352. E. Bagnicki, of New York. An improved syringing apparatus, for curing leucorrhea, and similar sexual diseases.

354. R. R. Rowntree, of Hull. A portable tea-testing apparatus.

356. J. B. Redman, of New Palace-yard, Westminster, Civil Engineer. An improvement in the construction of carriage ways.

358. W. Clark, of Chancery-lane. Improved protectors for tobacco plants. A communication from J. Romiguière, of Paris.

360. J. Juckes, of Dane-st., City-road. Improvements in stoves or fire-places.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Feb. 22, 1859.)

2248. A. E. Galliard. Portable fountains.
2251. L. Hope. Telegraph cables. A communication.
2257. C. F. Vasserot. Reflectors. A communication.
2266. T. Riddell. Window sashes.
2274. G. Beadon. Ships, boats, and vessels.
2288. C. Cowper. India rubber and gutta percha articles. A communication.
2293. S. Perkes. Extracting oil.
2295 G. Baxter. Colouring photographs.
2296. T. Archer, jun. Preventing boiler explosions.
2297. S. Diggle. Looms.
2302. G. Davies. Gloves. A communication.
2307. G. F. Wilson. Destroying blight, &c.
2309. F. J. Coulon and S. G. Giraud. Ornamenting leather.
2316. A. Dunn. Marking compounds.
2327. J. Smith. Rough-shoeing.
2329. J. Whitworth. Guns, carriages, and ammunition.
2330. W. F. Batho and E. M. Bauer. Screws, worms, and wheels.
2345. J. Wainwright. Ventilating.
2346. S. T. Clarke. Crossing cheques.
2372. W. E. Newton. Pumps. A communication.
2376. J. J. Welch and J. S. Margetson. Scarfs.
2379. T. and J. Ashworth. Power looms.
2383. S. R. Parkhurst. Cotton gins.
2396. A. Heywood. Drying fabrics. A communication.
2409. W. Monro. Capsules.
2436. W. Palmer. Fire-arms.
2439. M. A. F. Mennons. Voltaic electricity. A communication.
2477. L. Schwartzkorf and C. Philippson. Boring holes.
2620. E. A. Pontifex. External surface condensers.
2740. R. Laming. Purifying gas, &c.
2774. J. B. and J. Fisher, and J. Bird, jun. Furnace doors and dampers.
2788. J. G. Arnold. Envelopes.
2879. W. Morgan. Iron.
2987. T. Bell. Purifying gas.
104. C. N. May. Heat indicator.
147. W. Newman. Blinds.
148. J. Foster. Spinning and roving frames.
218. J. G. Proger and D. Davies. Signal lanterns.
230. H. Brecknell and J. Dyer. Cocks and valves.
249. H. Rawson. Preparing wool, &c.
266. J. Mac Kenzie. Operating ventilating valves.
267. J. Marino. Inodorous closet.
282. J. Hosking and T. Cock. Furnaces.
286. M. A. and R. Walker. Percussion caps.
302. J. Buncher. Eyes for stair rods.
326. P. Adie. Taking levels and measuring angles.
333. R. Tinkler. Churns.
352. D. E. Bagnicki. Syringing apparatus.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed February 18, 1859.

1880. A. V. Pinta.
1887. W. F. Padwick.
1890. W. Smith.
1891. W. Pearce.
1896. P. Spence.
1897. J. L. Piggott.
1905. W. Henson.
2035. J. U. Faessler-Petzi
2109. A. Turner.
2381. G. Kent.
2883. R. Mushet.
2921. R. Mushet.
2935. J. Broom.
2941. J. W. Child.

Sealed February 22, 1859.

1909. F. Puls.
1910. F. Puls.
1913. L. Higgins and A. Brown.
1917. J. H. Robinson.
1923. H. Wilson.
1927. T. Hill.
1933. J. Black.
1935. S. N. Rodier.
1938. T. Trotman.
1939. J. Ellisdon.
1943. H. W. Hart.
1995. J. T. Pitman.
2026. L. Pellissier, and J. Puytorac.
2052. J. Knowles.
2061. L. Hill.
2089. W. E. Cochrane.
2222. J. Ridsdale.
2868. D. Rowan.
2897. J. Clegg.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

391. E. Oldfield.
420. W. G. Merrett.
426. W. Muir.
431. J. Freer.
434. J. H. Johnson.
438. J. Barsham.
440. I. Moll.
442. J. H. M. Maissiat.
479. C. Iles.
514. C. A. de Fonbonne.
538. R. Maynard.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement :—

STEAM ENGINES, &c., 1422, 1424.
BOILERS AND THEIR FURNACES, 1419.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1430, 1434, 1373.
SHIPS AND BOATS, including their fittings, 1427, 1437, 1452, 1456, 1475.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1429, 1431, 1138, 1140, 1443, 1446, 1453, 1469.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1412.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1414, 1417, 1421, 1423, 1426, 1433, 1442, 1447, 1454, 1461, 1474.

Digitized by Google

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*
LIGHTING, HEATING, AND VENTILATING, 1418.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1416, 1455, 1462, 1477.
METALS, including apparatus for their manufacture, 1415, 1429, 1436, 1458, 1468.
CHEMISTRY AND PHOTOGRAPHY, 1411.
ELECTRICAL APPARATUS, 1449.
WARFARE, 1435, 1451.
LETTER PRESS PRINTING &c., 1432, 1459.
MISCELLANEOUS, 1413, 1421, 1425, 1428, 1434, 1439, 1441, 1444, 1445, 1448, 1450, 1457, 1460, 1463, 1464, 1465, 1466, 1467, 1470, 1471, 1472, 1476.

1411. P. BROWN and B. YOUNG. *Improvements in the manufacture of white lead.* Dated June 22, 1858.

According to this invention, nitrate of lead, however obtained, is placed in solution in a vessel, and submitted, until saturated, to the action of streams of carbonic acid gas, obtained, by preference, from the calcination of chalk, or carbonate of lime, in a closed retort. A coil of pierced pipe may be employed for effecting the distribution of the acid through the liquor. To the saturated solution the patentees next add an excess of caustic alkali, say caustic soda, which immediately enters into combination with a portion of the nitric acid that was before combined with the lead, and forms nitrate of soda. The metal thus liberated combines in its turn with the carbonic acid in the solution, and becomes converted into a carbonate of lead, which, being insoluble, immediately precipitates and falls to the bottom. The chemical action thus set up is continued until the nitrate has been converted into carbonate of lead. The supernatent liquor is then run off from the vessel, and the carbonate of lead is subjected to lixiviation in a strong solution of lime, assisted by the action of a stirrer, by means of which all the free acid remaining in the carbonate will be taken up or neutralised. After the carbonate of lead has been allowed to settle, the lime-water is drawn off. The precipitate, which is the pure white lead of commerce, is next to be removed from the vessel and dried either by natural or artificial means, after which it will be ready for the market. *Patent completed.*

1412. E., H. and F. C. COCKEY. *Improvements in apparatus employed in the manufacture of cheese.* Dated June 22, 1858.

This consists, 1, of a vessel (for cooling and draining the curd before it is ground or put into the vats) composed of a shallow perforated metal tray made to fit over a cheese tub, milk tin, &c., and fitted with metal feet or ledges for raising it slightly above the edge of the vessel beneath, thus allowing a free passage of air between the two. 2. Of a shovel or scoop, which consists of a perforated metal plate in a metal frame, with or without handles. This plate is by preference concave on the upper side. *Patent abandoned.*

1413. J. ROBERTSON. *Improvements in apparatus for regulating the flow or passage of fluids.* (A communication). Dated June 22, 1858.

As applied to regulating the supply of water to water-closets, this invention consists under one modification of a short cylindrical chamber of large diameter, having a top and bottom cover screwed on. The bottom cover forms the actual shallow shell or chamber through which the supply of water from the main is brought to the apparatus. This portion is cast in one piece on the supply pipe, being disposed horizontally, that is, with its plane parallel to the axial line of the main pipe which runs along it beneath. In the centre of this end disc or shell is an aperture communicating with the inlet section of the main pipe, whilst a second aperture slightly eccentrically disposed, communicates with the opposite or outflow section of the main pipe leading to the closet pan, the two apertures being of course completely separated by a sectional portion of metal cast in for the purpose. Upon this perforated disc shell face is fitted a circular disc of caoutchouc or other flexible material, arranged to bear upon an external annular face all round the shell. This flexible disc has screwed upon each face a button or small disc piece of metal, the under small disc having fitted to it a soft or flexible face piece of leather or other material to form a valvular fit upon an elevated annular working face round the central hole in the shell. The central or barrel portion of the operating chamber has attached to it a lateral water pipe of narrow bore, and fitted with a stop cock for setting the flow. The top cover or end of the disc of the chamber has passed through its centre a vertical spindle, fitted with a helical spring to keep it up. The lower end of this spindle which is passed through the cover has upon it a holding collar or button, to carry a second large flexible disc of caoutchouc, which, like the one already described, is of the same diameter as the cylinder's bore. The upper cover is dished on its inner face for the elastic disc to settle into, and leave more space beneath. The action of this apparatus is this:—When the closet is about to be used, the pressure upon the seat causes the main upper spindle to be depressed, and this spindle then forces down the upper flexible disc so as to contract the space for water in the cylinder beneath it, and thus force the contained water back through the lateral stop cock into the main, the water way through the stop cock being purposely adjusted to pass the water slowly through. Then, on the release of the operating spindle from pressure, the water in the main pipe beneath, meeting little or no pressure from above the disc to intefere with its upward force, lifts the bottom flexible disc, and flows through from the inlet section of the main by the apertures already diseribed into the outlet section, thus reaching the pan of the closet. This flow continues until the upper internal pressure between the two flexible discs in the cylinis made up by an inward flow of water again through the lateral stop cock, when the lower flexible disc will resume its seat, and cut off the supply of water to the basin or pan. The apparatus is then again fit for use. *Patent abandoned.*

1414. S. BARLOW. *Improvements in machinery or apparatus for bleaching or cleansing textile fabrics or materials.* Dated June 23, 1858.

The object here is to obtain a quick and perfect circulation of the bleaching or cleansing liquor through piece goods, yarns of linen, &c. A pipe or pipes is or are placed in a vessel fastened on a plate of iron, resting on the bottom; the pipes are perforated nearly to the bottom of the vessel, the plate also has holes round the outer edge. It can be used when the vessels works in pair or when a liquor vessel is attached to, or forms part of a single vessel. When the vessels are filled with goods and the liquor runs in, this apparatus causes it to circulate through the whole of the goods simultaneously. *Patent completed.*

1415. T. SPENCER. *Improvements in the treatment of iron ores, and ferruginous sands, and certain applications arising therefrom.* Dated June 23, 1858.

This consists in a method of treating iron ores and ferruginous sands so as to produce a new compound substance which may be applied to a variety of purposes. *Patent completed.*

1416. C. VERO and J. EVERITT. *Improvements in the manufacture of hats.* Dated June 23, 1858.

This consists, 1, in applying brims of felt or of gossamer covered with flock to hats, the bodies of which are made of straw, chip, palm leaf, grass, &c., plaited like straw. 2. In making hats with such bodies, having tops and brims made of felt or gossamer, and the whole having a covering of silk or woven fabric. Before this covering is put on, the body of the hat is covered with a flexible proofing which secures the silk and preserves the elasticity of the hat. *Patent completed.*

1417. P. J. LIVSEY and F. L. STOTT. *Improvements applicable to machinery for warping yarns or threads.* Dated June 23, 1858.

The object here is the stopping of warping machinery, or giving notice by self-acting means when a warp thread breaks, or is absent from its proper place, by arrangements in connection with that mechanism for dividing the threads or forming the lease in warping machinery, known as the "heck." It consists in arrangements combined with the ordinary heck, by which it is modified so that it performs its common office, and also serves the above purposes. The invention is not clearly described apart from the drawings. *Patent completed.*

1418. W. and J. CLIBRAN. *Improvements in apparatus or arrangements for distributing, governing the pressure of, and lighting gas.* Dated June 23, 1858.

This relates 1, to a mode of joining pipes used for the distribution of gas, the object being to preserve a perfect joint, and allow for the settlement or movement which takes place after pipes are newly laid out, and consists in employing the ball and socket arrangement to form the junction between the pipes. 2. To gas governors and stop taps, and consists in a peculiar combination of the two in one. 3. To small gas governors intended for single lights, and are particularly applicable to street lamps, and consist in a peculiar arrangement of the valve and passages intended to provide principally against the stoppage of such passages by the entrance of the mercury used as a seal to the gas holder. 4. To arrangements for lighting gas lamps, especially street lamps, the object being to light such lamps externally without removing or opening the parts protecting the light from the weather, and consists in the employment of a pipe, the orifice of one end of which is placed so as to come directly opposite and over the gas burner, the orifice of the other end of the pipe being brought to the outside of the lamp or protecting cover. *Patent completed.*

1419. R. ARMSTRONG. *Improvements in steam boilers and furnaces.* (Partly a communication.) Dated June 23, 1858.

The specification of this invention describes various modifications of methods of constructing steam boilers and furnaces, which we cannot give in detail; but the main object appears to be the production of an increased quantity of steam from a boiler of given dimensions, and with a given quantity of fuel, which object is effected by supplying the fire box with a number of peculiarly-shaped hollow vessels, or retorts, fixed across the furnace, and crossing each other from side to side. Within and through these the water is permitted to circulate, communicating freely with the surrounding water spaces at their ends. *Patent completed.*

1420. SIR J. PAXTON. *Improvements in the manufacture of horticultural buildings or glazed structures for horticultural and other purposes.* Dated June 23, 1858.

This invention was described and illustrated in the MECHANICS' MAGAZINE for January 7th, No. 2 (new series). *Patent completed.*

1421. R. RUMNEY, J. MELLOR, and W. S. MACDONALD. *Improvements in dyeing and printing cottons, wool, silk, and other materials and fabrics.* Dated June 23, 1858.

This refers to dyeing or printing with matters derived from uric acid, and consists in preparing cloth, &c., for the reception of the matter, so that it may become fast. The inventors employ salts of metals dissolved in caustic alkali, as for instance a solution of carbonate of lead in soda or potash; or they apply the salts of metals and alkalites separately. They also pass the material through dilute of sulphuric or other acid, and then treat it with an alkali or alkaline salt as silicate or plumbate of soda, to neutralize remaining acid. The matter is then applied as in ordinary printing or dyeing, and subsequently they apply a coating of some oleaginous substance. *Patent abandoned.*

1422. W. E. NEWTON. *Certain improvements in centrifugal governors for steam engines, and other motors.* (A communication.) Dated June 23, 1858.

Here a centrifugal governor, constructed on any of the usual plans with balls aud arms, but made lighter than usual, is employed, and driven at a high velocity. To the slide of the governor which connects it with the regulator, a counterpoise is employed, of a weight much greater than the aggregate weight of the balls and arms, and sufficient to balance the centrifugal force developed by the rapid revolution of the latter, and it is in this latter feature the invention principally consists. It also consists in so applying the counterpoise to the governor that its effective load on the governor shall be lessened in proportion as the balls and arms of the latter expand, so as to render its action constant, or as nearly so as may be desired. It further consists in the employment of the counterpoise as a means of controlling the exact speed of the engine or motor. *Patent completed.*

1423. C. BORDAS. *Improvements in the mode or method of producing embroidery.* Dated June 24, 1858.

Here a pattern being produced on the required material by stamping, tracing, or printing, the braid, &c., is worked over the pattern by any suitable stitch. *Patent abandoned.*

1424. J. BATES, J. YORK, and W. PARKIN. *Improvements in pistons and plungers.* Dated June 24, 1858.

The patentees place in the interior of ordinary metallic packing rings, a ring of metal made elastic by slotting it from the interior to within a short distance from the exterior, and from the exterior to within a short distance from the interior, the number and width of the slots being proportioned to the diameter of the piston or plunger and pressure that is to be resisted. In the elastic ring there is also transverse slot or key way, in which they insert a wedge or key which expands the ring to the necessary degree of strength, which wedge or key is replaced by a larger one when the packing rings require more expansion, on account of wear and tear. If the piston or plunger be of great depth, two or more elastic rings may be employed. *Patent completed.*

1425. P. GRIFFITHS. *Improvements in the manufacture of shaft couplings.* Dated June 24, 1858.

This consists in casting shaft couplings in iron moulds; the moulds have a core or mandril the same size as the shaft, the core being furnished with the form of key by which the coupling is fixed, and forms the key-way in the coupling. These can be at once removed from the mould, and fitted to shafts. *Patent completed.*

1426. G. COLLIER. *Improvements in means or apparatus for the stretching and drying of woven fabrics.* Dated June, 24, 1858.

Here the fabric is fed on to a cylinder heated by steam, the surface of which is roughened to hold the fabric distended till dried. Various means of feeding the fabric to the cylinder may be adopted. *Patent completed.*

1427. J. ROBINSON. *Improvements in applying and adapting water-closets to ships, so as to ensure the safety and more perfect ventilation of the same.* Dated June 24, 1858.

The pipe from each closet is connected to a main sewer pipe, which leads to an exhaust pump, which pump maintains a partial exhaustion of the sewer pipe, and thereby cleanses the closets, ventilates the ship, and ensures its safety, there being but one outlet for all the closets. *Patent abandoned.*

1428. W. E. NEWTON. *Improved machinery for manufacturing friction matches.* (A communication.) Dated June 24, 1858.

This consists, 1, in a cutting tool having a circular or convex and concave rollers, by which the match sticks are cut smoothly and easily from the bolt or block, after which they are presented to an endless chain of clamps, by which they are conveyed to the sulphur and igniting compounds. 2. In an endless chain of clamps operated so as to effect the object above-named, and also to allow of the discharge of the matches at the proper time and place. 3. In a discharging device arranged for discharging the finished matches from the clamps. This invention is not described apart from the drawings. *Patent completed.*

1429. J. H. JOHNSON. *Improvements in machinery or apparatus for making bolts and rivets.* (A communication.) Dated June 24, 1858.

This relates to machinery for pressing bolts and rivets, either hot or cold, and to a peculiar safety apparatus for throwing the machine out of gear when the strain upon it becomes excessive. *Patent completed.*

1430. R. PICKERING. *Improvements in apparatus for communicating signals from one part of a railway train to another.* Dated June 24, 1858.

Here a flexible tube is carried along beneath the bottom of all the carriages in the train, and terminates in a whistle at the part where the engine driver stands. This tube is in separate lengths for each carriage, provision being made for coupling the ends when the train is made up. Each carriage has extended into it a branch tube from the main line of tubing with a mouthpiece for blowing into. Each branch tube is brought up at one end of the carriage, and then turned into the carriage, beneath the roof, along which it passes, being fitted with a sub-branch, with a mouth piece and tap or valve for each compartment. *Patent abandoned.*

1431. C. W. CAHOON. *An improved machine for sowing seed or fertilising material or other substances broadcast.* Dated June 24, 1858.

A complete specification of this invention was filed with the application, and an abridgement of it was published at page 620, No. 1846, of the MECHANICS' MAGAZINE (old series). *Patent completed.*

1432. J. BETTS. *Improvements in obtaining surfaces on which to print maps and other designs.* Dated June 25, 1858.

The inventor applies to the foundation fabric a coating of pigment combined with boiled linseed oil, diluting the oil, if necessary, either with alcoholic or resinous spirit. After this coating is laid on it is scraped or rubbed until a smooth and absorbing surface is obtained; heat may be used if required. *Patent abandoned.*

1433. C. NIGHTINGALE. *Improvements in apparatus applicable to curling and spinning machines for horse-hair and other materials.* Dated June 25, 1858.

This consists in applying to machines for curling, spining, or twisting horse-hair, &c., conical speed pulleys for imparting to the reel or bobbin a rotary motion, slightly less rapid than that imparted to the flyer, so as to preserve the required relation between the speeds of the flyer and the reel or bobbin without retarding the motion of the latter by mechanical means. By driving both the flyer and the reel or bobbin independently but at the required

Digitized by Google

relative speeds the latter is carried round without depending for its required rotary motion on the pull of the hair, &c., the only strain on which being that due to the difference between the respective velocities of the flyer and the reel or bobbin. One of the conical pulleys is fixed on the driving shaft and the other on the spindle or axis to which the reel or bobbin is fixed, a cross strap or band communicating motion from one to the other. The slight variation in the speed of the reel or bobbin as it becomes filled with the material is produced by shifting the strap or band a short distance along the pulleys. *Patent completed.*

1434. T. BOOTH. *Improvements in mounting and fitting wheels and axles to carriages, which improvements are also applicable to pulleys and other parts moving on axes.* Dated June 25, 1858.

This consists, 1, in so fitting the axle to its bearings that the friction is distributed on many bearing surfaces, and the bearing surfaces so disposed that the weight of a carriage when traction force is applied thereto produces a tendency to onward motion. The inventor fixes the axles loose in their bearings, these bearings consisting of a number of rings placed one within the other. The smaller ring is fitted somewhat closely to the axle. The next ring is somewhat larger than the small one so that it has considerable play within it; the third ring is similarly adapted to the outer diameter of the second ring, and so on are the several rings disposed and fitted within each other; the outer ring constitutes a fixed bearing surface fixed to the carriage frame. The fixed bearing has annular plates fixed to it which partially enclose the sides of the several rings and keeps them in position; two other annular plates are secured to the axle which enclose the sides of the smaller rings and embrace the larger annular plates, thereby keeping the whole of the bearing rings in position. Stop collars, &c., are affixed to the axle for securing the several parts in position. The weight of the carriage resting on its bearings presses all the rings in contact with each other in a vertical line upward from the axle, and in a position eccentric to each other. When tractive force is applied to the carriage it throws this line of contact out of the vertical position, and the weight resting on the several rings in this line of contact now out of the upright gives the carriage a tendency to onward motion, and at the same time any rotary motion of the axle is distributed throughout the number of bearing rings. The improvements in mounting and fitting wheels to axles consist of a similar arrangement of rings placed one within the other, the axle being free to rotate within the smaller ring or bearing surface, which is of considerable thickness; a series of rings surround this bearing surface, which are all received and enclosed within annular plates fixed to each side of the wheels; between the annular plates and these rings he disposes annular surfaces of India-rubber as cushions to receive any side shocks; a plate of metal is interposed between the India-rubber and the rings as a friction surface; other annular plates are secured to the axle, which embrace the annular plates fixed to the wheel, which is thereby kept in position laterally with regard to the axle. *Patent abandoned.*

1435. P. R. SMITH. *Improvements in fire-arms and ordnance, and in the projectiles to be used therewith.* Dated June 25, 1858.

This consists, 1, in means of constructing the barrels of fire-arms which will make them last longer, and prevent them from bursting; 2, in the use of certain pieces which, added to the projectiles, will give to the fire-arms when smooth inside the same advantages as the rifled ones. Under one modification, the inside part of the barrels are of iron or steel, and a long conical cylinder composed of several metals is mounted upon it, and occupies nearly the whole length of the barrel. Upon this cylinder are placed rings of two thicknesses, screwed one with the others, and placed so that the joints of the rings of the first thickness are covered by the centre of those of the second. The outside ring, which corresponds to the place where the pivots are to be, is made with the same pivots. The touch-hole is formed by a pin screwed in the two pieces, and in the centre of which two holes are made, one in a straight line and the other obliquely, and the nipple which is to receive the percussion-cap is placed upon one of the said holes. To do away with the helical rifling inside the fire-arms, the inventor makes use of directing-pieces, which are composed of one bottom and some inclined branches. The projectiles are furnished with grooves inclined towards the axis. The said grooves are destined to receive the branches of the directing-pieces. *Patent abandoned.*

1436. J. MAUDSLAY. *An improvement in the construction of furnaces for melting iron, steel, and other metals.* Dated June 25, 1858.

This invention was described and illustrated at page 29, No. 2, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

1437. J. WESTWOOD. *Improvements in the plating of ships and floating and other batteries, to render the same shot-proof.* Dated June 25, 1858.

The object here is to cover the exposed parts of the hulls of ships, and also of batteries, with plates of iron or steel of sufficient thickness to resist heavy shot. This the inventor proposes to do by the use of rebated plates, which will form some lap-joints. In covering the exposed parts of the hulls of wooden ships with these plates, he uses screw-bolts for securing them in place; but for iron ships he prefers the use of rivets. By rebating the adjoining plates and getting a good lap, one row of screw-bolts or rivets will suffice. To prevent the shot from striking the bolt-heads, he proposes to sink them in the bolt-holes in the plates. Instead of bolting the plates directly to the planking or plates of the ship, he proposes to bolt or secure thereto parallel lines or nearly so, ⌊, or ⊨ shaped angle iron to receive the lines of rebated plates, and by means of their flanges form with the plates overlapping joints and hold the plates securely in position. *Patent abandoned.*

1438. J. TAYLOR. *An improvement in the construction of horse-hoes, applicable also to drills.* Dated June 25, 1858.

This consists in mounting the hoes on independent levers, which are severally jointed to the forward end of a balance frame capable of rocking and sliding upon its fulcrum, and can therefore be moved vertically and horizontally by the same guiding shaft or lever. *Patent completed.*

1439. P. M. CRANE. *Improvements in the manufacture of fuel from peat.* Dated June 26, 1858.

Having cut the peat (as it is found in the bog) in suitable pieces or sods the inventor covers them with cloths of woven textile fabrics. He then subjects these pieces or sods to hydraulic pressure. The hydraulic press the inventor prefers to be of about 200 tons power. The pieces or sods are next removed from the press and dried in the open air or otherwise. *Patent completed.*

1440. T. LEMON. *Improving Cartwright's original patent chain harrow.* Dated June 26, 1858.

A complete specification of this invention was filed with the application. The invention is not described apart from the drawings. *Patent abandoned.*

1441. W. L. TIZARD. *An improved method of treating brewers' and distillers' malt or grist.* Dated June 26, 1858.

This consists in subjecting malt or grist, after it has undergone the usual processes of grinding and saturating with water, to trituration or mastication. This may be effected in a variety of ways, of which the following will serve for an example:—A series of open floors or discs may be made (of either wire gauze or wire cloth, wood or metal) to occupy nearly one half of the diameter of, say, a mash-tun or vessel, each fixed to a frame carried round the central shaft of the mashing gear; on each floor is placed a similar disc, through each of which a shaft passes, and on motion being communicated to the shaft the upper discs revolve on the floors, macerating the grain or grist between their surfaces. The immediate consequences of this trituration or mastication are to convert the whole of the farinaceous matter, together with the hordein (hitherto considered inconvertible) into valuable wort or wash. *Patents completed.*

1442. S. WHITEHALL. *Certain improvements in finishing lace and other fabrics.* Dated June 26, 1858.

This consists in using a glass roller in the pressing of lace or other fabrics after the "dressing," by which a more cleanly appearance and lustre are given to the goods. A reel may be attached to the roller on which the fabric can be wound. *Patent completed.*

1443. W. WOOFE. *Improvements in implements for paring, hoeing out, and clearing land, and for depositing seed.* Dated June 26, 1858.

This consists in improvements in an implement for which a patent was granted to the inventor 27th Nov., 1856. In the specification of his former patent the inventor shows the turnfurrows fixed to the stem by a bar rising from the stem. Now, for such purposes as raising turnips from the row, it is necessary to remove the turnfurrow, and that there may be no impediment, he removes the bar rising from the stem, and connects the turnfurrow to the stem by a bolt carried from the back of the turnfurrow down through the stem. Thus, when the turnfurrow has to be removed, there will be no parts to interfere with the proper action of the implement as a parer, or hoer out, or cleaner of turnips, &c. To make the implement act as a drill he fits on to the axle of the hind wheel, which is prolonged for the purpose, one or more sheaves, over which a band is passed communicating with a revolving wheel or dropper fixed under a seed hopper placed at the rear of the beam of the implement. For some purposes he fits a revolving pulveriser or harrow in the shape of a boss with radiating arms or tines upon the axle of the hind wheel of the implement, the axle being prolonged for its reception. Lastly, he fits a tip of steel upon the share or stem, and makes a notch in the turnfurrow at bottom for its reception. *Patent abandoned.*

1444. J. A. MANNING. *An improved mode of intercepting and treating the sewage of London, and towns and cities similarly situated.* Dated June 26, 1858.

Here the inventor proposes to connect (by a closed tubular drain or pipe) the mouth of each sewer emptying itself into the Thames to a building erected at low-water mark, and containing two tanks of a sufficient capacity to receive the flow from such sewer for one or more hours. In cases where two or more small sewers can be conveniently combined they may all be made to discharge into one set of tanks. The several tubular connecting drains, and the depositing tanks with which they are connected, are entirely shut off from all communication with the river. In the lower levels the tanks will be of such an increased depth as to insure the constant flow of the sewage, whilst the connecting tubular drains will be so supported above the surface of the river strand as to prevent the tilting of the mud against its sides. The tubular connecting pipes are made with forked branches, one leading to each of the depositing tanks, and each of these branches has a sluice or other stop valve so that one tank being filled the flow of sewage will be directed to the second tank. During the time occupied by the filling of the second tank the precipitating all the animal and vegetable organic matters held in suspension in the sewage contained in the first tank, as well as the deodorization both of the solid and liquid portions of the sewerage and the clarification of the water, together with the discharge of such clarified water into the Thames, are accomplished, such operations being carried on continuously from each tank in rotation, so that at no time is the regular flow of the sewage impeded. The operations of precipitating, deodorizing, and clarifying may be effected by any suitable method. *Patent abandoned.*

1445. T. V. FLINN. *Improvements in sash-bars for the purpose of drainage.* Dated June 26, 1858.

This invention is for collecting the leakage through glazed frames into gutters to be formed in each sash-bar, under the rebate for the reception of the glass; the bars are widened on the under-side to allow the gutter to be formed; a similar channel is made in the sides of the frame. The water thus collected may be run off by other gutters, or by holes cut in those already made. *Patent abandoned.*

1446. D. CAMPBELL. *A new grubbing and harrowing land-roller.* Dated June 26, 1858.

The object here is to do the work of both grubbing and harrowing in one machine; for this purpose it is proposed to use a strong framing having shafts attached for the horse or horses. At the bottom and between the sides of the framing is placed a roller, having fixed upon its surface, alternately rows of metal spikes and spade-shaped pieces of the same length as the spikes. As this roller revolves, it will both grub and harrow at the same time, and save labour in cross ploughing. For easy conveyance, a pair of wheels are placed on the ends of the rollers. *Patent abandoned.*

1447. E. PINCHON and W. R. HARRIS. *Improvements in machinery for manufacturing healds or harness used in looms for weaving.* Dated June 26, 1858.

This consists in manufacturing healds or harness by self-acting machinery or apparatus; counting the healds as they are made, marking the tokens, stopping the machine when any given number of healds are made, or when the heald's twine spools become empty, or when the twine becomes too slack on the spools, or when it breaks, thus making the machine so perfect as to require little attention on the part of the operative, and enable one person to work several machines at the same time. The inventors use two centre or foundation cords, proceeding from stationary spools, upon which the cords are so arranged as to pass in a vertical manner between the take-up cylinders at any required distance apart, for making any depth of heald or harness desired; the ends of the said cords are so arranged as to allow a twine or yarn to be carried around them, and in contact with hooks and needles, operating so as to form the tress to hold the healds firmly to the cords. They employ two fixed wires descending between the aforesaid cords in a parallel direction, and between the cord cylinder shafts to receive the healds as delivered by the take-up motion or cylinders, and they employ a fixed centre-piece, round the lower part of which are formed the heald eyes or loops, through which the warp threads in the loom are intended to pass. They also use a moving frame for carrying two heald twine boxes, and a peculiar arrangement of mechanism to catch and hold properly the said twine boxes as they are driven forward and backward upon the frame. *Patent completed.*

1448. E. E. D'HERELLE. *Improvements in boxes for keeping and measuring coffee, tea, and other substances requiring to be preserved from contact of the air.* Dated June 26, 1858.

This consists in providing boxes or vessels in which tea, coffee, &c., are kept with a top-piece forming a measuring chamber connected to the box by a register cock for either closing the box or allowing of communication between the same and the measuring chamber. To fill the measuring chamber the box must, of course, be turned upside down. *Patent completed.*

1449. W. H. PEECE and J. L. CLARK. *Improvements in electric telegraphs.* Dated June 26, 1858.

The ends of the line wires are each, as heretofore, bound round or fixed to an insulator fixed to a terminal arm on a post or upright; a leading-in wire coated with gutta percha is attached to the end of each line wire near where it is fixed to the insulator, and such coated leading-in wire passes up through a tubular insulator which is fixed at its upper part into a hollow cast-iron arm. The coated leading-in wire having passed into the hollow arm from the tubular insulator is conducted down in a hollow in the post or upright to which the arms are fixed. The hollow interior of the insulator and the arm where the coated wire passes are filled up with cement. By these means the portions of the leading-in wire which are within the insulator and the arm will be protected, and the insulation insured. The leading-in wires are attached to the line wires by binding screws, intermediate of the tubular insulators and the line wires. It is preferred that the tubular insulators through which the coated leading-in wires pass into the hollow arms should have an inverted insulating cup surrounding the hollows or tubular central part. *Patent completed.*

1450. C. ERHARD. *Improvements in apparatus for boring wells.* (A communication.) Dated June 26, 1858.

To keep up a constant flow of water past the boring tool, to remove the earth, &c., cut away thereby, the tool is connected to the end of a tube of less diameter than the diameter of the boring tool, which tube passes up to the top of the well, and to which a to and fro motion is given. Water is supplied to the space between the exterior of the tubes and the sides of the well, and the water is caused to rise constantly up the tube by a piston in which there is a valve opening downwards, being attached to the exterior of the tube near its top, which piston works in a cylinder through which the tube passes. The bottom of the cylinder is open, and at the top of the cylinder there is a valve opening downwards, which allows the water to pass downwards, but will not allow it to return back. By these means the piston in its downward stroke forces the water down the space between the sides of the well and the tube, and up through the tube, carrying with it the matters removed by the cutter, and the tube being open at the top allows the water containing the earth and matters removed by the boring tool to pass away freely. In place of the boring tool being permanently attached to the tube which passes up to the top of the well, the boring tool is attached to a short tube which slides on its end, and on the tube which passes up to the top of the well there are two levers which turn on tentees, the levers having notches formed in them, which take into projections formed on the tube to which the tool is attached, and so raise the tool when the tube which passes up to the top of the well is raised, but when the tube is raised to its highest point the catches are released and allow the tool to fall. *Patent completed.*

1451. I. HAMMOND. *Drawing the cartridge case from the barrel of a breech-loading gun.* Dated June 28, 1858.

According to this invention the barrels are secured by a tumbler seated in the breech in the front of a lump on the barrels at the breech end, and connected by a pin in the fore part of the breech; a lever attached to the tumbler under the gun in front of the trigger guard, by being turned a quarter of a circle, causes the barrels to fall down

Digitized by Google

in a position for loading, at the same time the empty cartridge cases are withdrawn from the barrels by a self-acting spring lever sliding through the lump under and between the barrels, one end clipping the brass end of the cartridge, the other end being acted upon by an inner pin attached to the breech. *Patent completed.*

1452. J. LUIS. *An apparatus permitting the different parts of machinery working in the water of screw vessels with wells to be examined and mended.* (A communication.) Dated June 28, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1453. J. LUIS. *An improved machine for reaping corn.* (A communication.) Dated June 28, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1454. J. MORGAN. *Improvements in machinery or apparatus for manufacturing or spinning rope yarns or other yarns.* Dated June 28, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1455. G. MORRIS. *An improvement in shirt and other collars.* Dated June 28, 1858.

This consists in making the band of the collar longer so as to project at both ends beyond the flap or fold, and in cutting a slit in the direction of the length of the band in each of the projecting ends of the band. When on the neck these slits come opposite to each other, and serve for the reception of a tie. The tie is passed through the slits and made into a bow, without being passed round the neck. *Patent abandoned.*

1456. J. C. COOMBE. *Improvements in the method of, and apparatus for, manufacturing manures from fecal and other matters.* Dated June 28, 1858.

The inventor prepares a retort with a large amount of evaporating surface, and fixes with it a fan to be thrown into action at will; he also arranges the head or cover with compartments which permit of vessels being suspended or enclosed for containing deodorizing or disinfecting chemicals. He places fecal matters in the retort, and mixes with them magnesian limestone or other salt, and by the agitator renders the mixture homegeneous. He heats the retort by steam and continues to dessicate the mass till nearly deodorized, which he effects by chlorine gas, &c., which he generates and liberates at will from the chambers in the head of the retort, and which absorbs or decomposes the noxious gases set free from the mass. To the compound now found he adds soluble super-phosphate of silicates and then continues the dessication in the retort until the mass becomes nearly dry. It may then be ground up and mixed with blood, peat, charcoal, &c., as required. *Patent abandoned.*

1457. C. W. SIEMENS. *Improvements in cleansing tidal rivers.* Dated June 28, 1858.

This consists in procuring an influx of pure sea water at any desired point, whereby a rapid discharge of the sewage matter flowing in the river towards the sea is effected, and putrefaction of the sewage, owing to the salt in the water, is prevented. The inventor constructs a partition wall or dam longitudinally in the bed of the river from a point at or near the mouth of the river to a point at or above the populous district, dividing the river into separate channels. One of the channels has a trap-door, or valve, or gates, to allow of the influx of water from the sea, but which prevents the water from receding with the tide toward the sea. The water thus trapped is allowed to move forward and discharge itself into the unobstructed channel at a point where its purification is required. *Patent abandoned.*

1458. W. E. NEWTON. *An improved mode of, and apparatus for, making nails.* (A communication.) Dated June 28, 1858.

This machine is so constructed that by a simple change of cutters it will make nails of different sizes and forms, inasmuch as a heading apparatus need not be used, whilst it will cut a nail having a shoulder at all four of its sides. The invention relates to that class of nail machines in which a rotary disc cutter and vibrating anvil are used. The apparatus is not described apart from the drawings. *Patent completed.*

1459. W. E. NEWTON. *A new mode of applying engraved plates, or electrotype or other substitutes for such plates, to the cylinders of printing presses, and of applying other parts of such presses in combination with the cylinders to enable perfect impressions to be taken from the cylindrical surfaces of the plates.* (A communication.) Dated June 28, 1858.

The object here is to print very rapidly from engraved plates, &c. The surface of the plate to be printed from has a cylindrical form, so that it may be made to rotate and produce the impression on the paper, &c., as the latter moves between it and another rotating surface. The invention consists, 1, in backing the plates with a flexible but inelastic metal, and winding them upon the periphery of the printing cylinder, by drawing and bending them between the latter and the periphery of the feeding and impression cylinder, so as to make them bear evenly and solidly upon every part of the first-named cylinder, and securing them firmly thereto. It also consists in a mode of applying a clearing roller in combination with the printing cylinder and the inking roller, for removing the superfluous ink from the surface of the plates after the inking operation. Also in a method of appyling an endless band to clear and polish the surface of the plates between the engraved lines or sunk portions which produce the impression. *Patent completed.*

1460. B. YOUNG and P. BROWN. *An improved method of collecting and disposing of the sewage of towns and cities.* Dated June 28, 1858.

This consists in collecting sewage in covered tanks, and in allowing the liquid to drain off, while the solid portions are preserved. The noxious fumes are drawn off by an exhausting apparatus and consumed in a furnace. *Patent completed.*

1461. F. A. CALVERT. *Improvements in machinery for cleaning and preparing cotton, wool, and other fibrous materials.* Dated June 29, 1858.

This invention consists, 1, in applying collars at the ends of the wire-toothed cylinders, for which a patent was granted to the inventor in 1849, to prevent the cylinders coming in contact when in combination; 2, in so constructing the teeth of cylinders working in contact with a doffer that the fibrous material is not carried past the doffer, thus keeping the teeth clear: this is accomplished by weaving steel wire into a warp of cotton, the wire projecting beyond one selvage; this wire web is then folded together and secured in clamps to the surface of the cylinder, thus forming what is termed a wire brush; 3, in a combination of toothed wire rollers and upright grids forming a carding engine. *Patent abandoned.*

1462. E. STEVENS. *An improved cooking utensil.* Dated June 29, 1858.

This relates to baking dishes, and consists in combining a stand upon which meat may be roasted or baked; it serves as a pudding or pie dish, and a stew pan, and vegetables may also be cooked in it. *Patent abandoned.*

1463. J. SHAW. *A machine to manufacture square paper and other bags.* Dated June 29, 1858.

This invention is not sufficiently described apart from the drawings to render the various operations of the machine intelligible. The machine is of a rectangular shape, and partly made of iron. *Patent completed.*

1464. J. SHAW. *A machine to manufacture conical paper and other bags.* Dated June 29, 1858.

This invention is not sufficiently described apart from the drawings to render the various operations of the machine intelligible in an abstract. The machine is of a square or oblong form, and made partly of iron. *Patent completed.*

1465. J. HARCOURT. *An improved adjustable spindle for locks and latches.* Dated June 29, 1858.

This consists in forming the spindle with a deep lengthway groove on one side, in which a small piece of metal slides, which piece of metal is flat on the top, but made to taper from the ends on the under-side to an angle, so that looking at it sideways it assumes the form somewhat of a double wedge, that as the handle is put on the spindle and the double wedge so placed that the screw-hole of the knob shall be over the inner end of the double wedge, when it is in a position to be secured simply by turning in the small screw in the neck of the knob in the ordinary way, when it will depress the inner end of the double wedge and elevate the outer one, or the part that is within the knob, so as to make it impossible for it to be pulled off; thus, the meeting of the two inclines forming the wedges forms the fulcrum on which it acts. *Patent abandoned.*

1466. H. N. NISSEN. *A method of preparing paper for receiving stains or copies from letters and other writings.* Dated June 29, 1858.

This applies to that description of paper used in a damp state for taking press copies of letters, &c. It consists in preparing the paper by impregnating it with a solution of catechunic acid and iodine, whereby the paper upon being damped with clear water, will receive a stain from ordinary writing ink. *Patent abandoned.*

1467. W. BAKER. *Improvements in constructing covered ways for the passage of sewage on the banks of rivers.* Dated June 29, 1858.

A covered way is constructed along the sides of a river by cast iron plates; piles are driven parallel with the bank, which is either protected by a wall or by cast iron plates. On the piles a top or bearing plate is fixed, on which the lower ends of the cast iron plates are fixed. The upper part of the channel or way is covered over with cast iron plates which rest on the bank and on the upright cast iron plate. Where the width is considerable, a row of cast iron pillars are employed to support the covering plates of the covered way. Near the upper part of the upright plates are doors to admit of an overflow, and other doors to admit of the flow of water from the river into the covered way at high tide when it is desired so to do. The ends of the several sewers along the banks enter the covered way, and the sewage therefrom passes from the sewers into, and flows off by the covered ways. Provision is made for passing the ends of canal docks and other navigable places. *Patent abandoned.*

1468. H. GREAVES. *Improvements in apparatus for moulding, casting, and coating metal articles.* Dated June 29, 1858.

For moulding and casting, the inventor makes use of a horizontal frame, supported, and capable of revolving upon, a vertical axis. This frame is situated above a corresponding bench, upon which the moulding boxes or flasks employed rest when required. The moulding boxes or flasks are suspended at intervals to the circumference of the frame, and have gudgeons which rest in corresponding bearings suspended from the frame, and thus allow of the boxes or flasks being turned over. The pattern of the article to be moulded is placed upon a moulding board which rests upon the bench before-mentioned. The moulding box is then lowered down upon and attached to the board and the sand rammed in. The box is next raised clear of the bench, and turned over so that the moulding board comes uppermost. The box is then again lowered so as to rest upon the bench, and the moulding board removed. A second box or flask is then placed upon the first and rammed up; after which the top box may be taken off, the pattern removed, and the top box replaced in the ordinary manner. The frame is placed so that one side is near to the mouth of the cupola from which the articles are to be cast. In using the apparatus, the boxes after being filled are raised clear of the bench, and the frame swung round so as to bring them successively opposite to the cupola where the metal is run in. They are subsequently emptied, and by the rotation of the frame again pass into the moulder's hands to be refilled. The frame is caused to rotate by manual or other power. *Patent abandoned.*

1469. P. P. C. and J. B. BARRAT. *Improvements in machinery for digging, reaping, mowing, and performing certain agricultural operations, and for cutting drains and excavating, partly applicable to arrangements for communicating motion for other purposes.* Dated June 30 1858.

This invention is not intelligibly described apart from the drawings. *Patent completed.*

1470. W. S. WHEATCROFT and J. N. SMITH. *Improvements in locks, fastenings, or safe-guards, making them self-acting, or partially self-acting.* Dated June 30, 1858.

This consists in placing in the interior of the safe, &c., in connection with the inner side of the door, an apparatus acted upon by an elastic spring or other similar power, worked in the same manner as the movements of a time-piece, the working parts of which the inventors connect to the bolts of locks, or to simple catch-bolts alone. They apply a series of levers and notches fixed in such positions as to be in connection with the fastenings or bolts; and they also fix a dial or indicator to be acted upon by the said apparatus, the winding up and setting of which will indicate the exact or desired time of liberating the bolts or fastenings. *Patent abandoned.*

1471. S. FATTORINI. *An universal meridian applicable to mathematical, geometrical, and precise instruments.* Dated June 30, 1858.

This invention consists in dividing the circumference into 384°, and in the application of the said division to any instrument of precision used in mathematical, geometrical, astronomical, nautical, or other operations or calculations for measuring time and distance, &c. *Patent abandoned.*

1472. B. NICOLL. *Improvements in circular knives and saws.* Dated June 30, 1858.

This consists: 1st. In the use of cutters or knives and saws of a circular form, but perforated or open instead of being plain discs as heretofore. 2nd. In certain mechanism for actuating these cutters and saws, and which vary according to the purposes for which they are intended. These cutters, or knives and saws, are used in either a horizontal or vertical position, and may be applied to any cutting or sawing purposes. The invention is not described in detail apart from the drawings. *Patent completed.*

1473. W. CAPSTICK. *Improvements in wheels for carts or vehicles to run on common roads.* Dated June 30, 1858.

This relates to constructing cast or wrought iron naves and combining them with wrought iron spokes and wrought iron rims or treads. The naves are fitted with a bush of cast or wrought iron, brass, &c., which, when placed in the nave, is secured therein by keys or wedges. Instead of an ordinary linch-pin, a round head or cop peice is placed on the end of the axle, and prevented from turning round by a feather or cross bar on the under-side of the cap piece, which is fitted in a groove cut out of the end of the axle, on which it is secured by a stud screw, which passes through the cop piece, and enters the end of the axle. *Patent abandoned.*

1474. J. PETRIE, jun. *Improvements in machinery or apparatus for drying warps of yarn or thread and woven fabrics.* Dated June 30, 1858.

This consists in an arrangement in which the apparatus which conveys heat and the chamber in which the articles to be dried are caused to travel, and also the necessary apparatus for effecting such motion, are combined together so as to constitute a machine complete in itself. Thus the patentee constructs a chamber provided with rollers over which the yarn or cloth is caused to travel in a vertical direction. Beneath he places a steam pipe or other source of heat, and under that a revolving fan for driving the heated air upward, the whole being connected together by suitable framework. *Patent completed.*

1475. H. G. PEARCE. *Improvements in reefing the sails of navigable vessels.* Dated July 1, 1858.

To apply this invention to (say) top-sails, a horizontal supplementary bar is fitted across the sail equidistant between the head of the sail and the close reef. This supplmentary spar is attached to the sail, and is suspended at the ends on axles by ropes or chains, which reeve through blocks or chocks on the top-sail yard arms, and are carried to the centre of the yard, where they are passed through blocks or chocks for convenience of working. The centre of this supplementary yard, which revolves, is fitted with a boss to receive a "parbuckle" or "semi-parbuckle," one end of which is attached to the supplementary revolving yard, and is passed several times round it, and from thence to a hole or block at the top-mast head, and down to the deck, where it is made fast, thereby causing the sail when dropped down to roll itself up both from above and below, and when twisted to unrol itself as the sail is elevated. The supplementary revolving yard is connected to the mast by two hoops, which are connected together and encompass the yard on each side of the parbuckle rest, and are secured to a "parrall" or hoop that works on the mast. The sail is split in the middle from the upper yard to a little below the close-reef, to admit the centre gear to work through it. *Patent abandoned.*

1476. T. WHITELEY. *Improvements in the manufacture of millboard, and in machinery or apparatus for cutting millboard and paper.* Dated July 1, 1858.

This invention was described and illustrated at page 76, No. 5, of the Mechanics' Magazine (New Series.) *Patent completed.*

1477. W. CLARK. *Improvements in grid irons.* (A communication) Dated July 1, 1858.

This relates to new and economical gridirons, the bars of which are over-lapped and raised one above another, and forming a surface impassable in a line perpendicular to the general plane of the bars, whatever form the gridiron possesses. The bars may be single or double, and form, with the cross pieces, a flat, curvilinear or angular surface, at any degree of inclination. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, MARCH 4, 1859.

HIGH SCIENCE.

MODERN science never, we presume, rises higher than when Dr. FARADAY expounds it to a brilliant audience presided over by the Prince Consort. This we say mainly, of course, in a worldly sense; for who would limit the absolute flight of so pure and transcendent a thing as scientific truth to the region of earthly royalty? But speaking, we say, in a worldly sense, the FARADAY evening at the Royal Institution, brightened by the presence of the husband of our Queen, and the father of our future kings, is *the* period when the star of science culminates. Such a period was last Friday evening.

Although somewhat less at ease, and less fluent than usual, Professor FARADAY on that occasion ably brought before his crowded and, for the most part, distinguished audience, a subject of much interest and significance, viz., the discoveries of Messrs. BRODIE and SCHONBEIN in relation to those forms of oxygen known as "ozone" and "antozone." By numerous and varied experiments, he showed the capability which oxygen has of being transformed into two opposite states, in which it is known by these names, and also the facility with which the ozone and antozone may be combined, and made to take the form of pure oxygen. Philosophers at present content themselves with performing these experiments, and explaining the facts; but it is easy to see that our theories of ultimate elements, definite proportions, and so forth, are not a little loosened and shaken by such discoveries; and when (as Dr. FARADAY remarked) it is remembered that oxygen constitutes more than one-half of our entire globe, the light which is likely to be thrown by them upon terrestrial phenomena may prove to be indeed wonderful.

Our prime object, however, in referring to the proceedings of last Friday evening, is a much more humble one than that of considering an exalted question of chemistry, or even that of noticing the princes, and bishops, and earls, and duchesses, and other illustrious amateur friends of science who took that question into their polite consideration! We desire simply to direct attention to the claim which Professor FARADAY, on that occasion, as on former occasions, most earnestly and impressively made on behalf of experimental science, viz., that it exerts an immediate and powerful influence upon the welfare and progress of society. It has been fashionable for persons of all classes to consider the devotees of experimental science as a class who feel no interest in, and have no care for, the practical arts and industries of life. But this shallow and fanciful habit is heartily denounced by Professor FARADAY—a man who has the best right to speak upon it. It is not alone, he tells us, for the educational benefits which arise from the study of physical phenomena and laws that he and others pursue their inquiries. These benefits are undoubtedly valued, and are felt to be of themselves worth far more labour than is bestowed upon their acquisition. But in addition to these, the experimentalist looks with pride upon those practical fruits which his devotion has fostered, and with confidence anticipates like harvests in the future. The steam-engine, the electric telegraph, and other world-transforming and world-bettering agencies declare his honour, and it is folly to suppose him insensible to the fact.

Although the practical rather than the abstract is our domain, we cordially recognise the claim thus put forth, and feel assured that practical men everywhere will assent to it. Did we not, we should blush for them. It is in the nature of things that the facts discovered by the experimental philosopher should be caught up by eager commercial men, and turned to their own pecuniary advantage. But let it not be said, or even thought, that those wide-spread classes who extract convenience and profit from the philosopher's labours are unmindful of his claims. He does not ask for fortune, or even for large material benefit of any kind; but let him not be denied what he does require—the acknowledgement of his generous exertions in furtherance of both the material and the mental prosperity of his country and the world.

MINERAL DISCOVERIES IN FRANCE.

IT has long been known to men of science that France contained a far greater amount of mineral wealth than the importance of her mining operations would lead one to suppose, and M. Michel Chevalier—whose intimate acquaintance with English trade and commerce has made him one of the most valuable advocates of the freedom of commerce in France, and whose appointment as a Member of the Council of the New Minister for Algeria and the Colonies, Prince Napoleon, holds out some promise of the application of sound economical principles in the future administration of the colonial possessions in France—gave his countrymen a hint, in his "Letters on the London Exhibition of 1851," that what had been done in Scotland and Wales with respect to the production of cheap iron, might be done, if not quite so extensively, still largely in France, where the natural vicinity of fuel and mineral was less uncommon than generally supposed.

Scientific men have lately been busily engaged in examining the sources of mineral wealth, and amongst these M. THEODORE LAGRANGE is one of the most conspicuous. The results of his researches have been submitted to analysis by M. M. PAYEN, PONISOT, VILLAIN, and DUMOULIN, and are just now published.

The districts examined by M. LAGRANGE are described as being the most sterile portions of the south of France, and as having been previously considered destitute of any mineral wealth of importance. It would have been more satisfactory had M. LAGRANGE given us the names of the localities, but, at the same time, the high respectability of the names attached to the report brings the latter before the public with great prestige.

The minerals in question consist of galena, described as rich and containing more or less silver and antimony; sulphuret of lead, very rich; iron ores, containing 84 to 86 *per cent.* of metal; iron pyrites; schists, both aluminous and bituminous; alimites, or "mountain butter;" copper ores; mineral bitumen; crystallized and amorphous sulphates of lime; sulphate and carbonate of barytes.

The reports of the chemists describe these minerals as very rich, and as deserving the serious attention of capitalists, who are advised to make an attempt to develope this industry, and thus produce for French manufacturers, from the soil of France, what at present they purchase in large quantities from foreign countries at a high price.

The specimens of galena analysed are reported to contain from 70·20 to 77·80 *per cent.* of lead, and from 0·030 to 0·05 *per cent.* of silver, which latter proportions are considered by Messrs. PAYEN and POINSOT to be sufficient to pay for the separation of the metals.

The bituminous minerals are reported to yield 80 to 82·20 per cent. of bitumen.

The analysts report also indications of strontium, zinc, manganese, tin, arsenic, chromium, antimony, magnesium, cobalt, and nickel. It is further remarked by these gentlemen that the presence of pyrites in nodules, fossil shells, and bituminous schist are the precursors of great coal-beds.

M. LAGRANGE is a man of large means, and he has given a long time, and expended much money, in his mineralogical investigations; but practical men will, at present, regard the subject as scarcely yet come within their circle. Besides, the possession of the means of wealth is not always allied with the habit or the talent for its development; and many may think that an impetus given to the mining industry of France would be even more important than the discovery of new mineral sources. However, the discovery of such important elements of material civilization can never be uninteresting, and must now, or at some future period, be useful and profitable also. The exhaustion of the coal-beds of England seems to recede from our minds as we advance, but *when* that event occurs it will be well to have a rich carboniferous neighbour.

THE ROYAL NAVY.

THE elaborate speech of Sir JOHN PAKINGTON on the navy (parts of which unfortunately got out of their places in the *Times'* report), claims some consideration from us. Much of it lies beyond our sphere; and even those portions of it with which we are more immediately concerned are too lengthy to be reported in full in our columns. We shall content ourselves, therefore, with glancing at the leading points brought under discussion.

Sir JOHN'S great work was, of course, to explain the causes which have led to the enormous magnitude of the next year's naval expenses. Let us notice some of them. The great advance in the cost of ships, occasioned by the introduction of steam, is the most serious. The cost of the hull of the *Indefatigable*, a 50-gun sailing frigate, in 1852-3, was £51,836; but the hull of the *Shannon*, a 50-gun steam frigate, four years later, cost £71,112; and that of the *Orlando*, a new frigate launched last summer, no less than £99,375.

"I can give," said Sir John, "another proof of the same thing in a different way. The construction of the *Britannia*, 120 guns, required 4,550 loads of rough timber and 218 shipwrights, while the *Marlborough*, the same class of vessel, recently built, required 6,068 loads of timber and 334 shipwrights. So that here, again, you have a proof of how much more costly it is to build ships in these days than it was a few years ago. The *Rodney*, again, required 3,610 loads of timber and 219 shipwrights, while the *Renown*, a vessel of the same class, but lately built, required 4,680 loads of timber and 277 shipwrights."

The increase in the size of our ships has also led to a great augmentation in the votes for new works. The costly slips and docks, which were of ample dimensions in times past, have now to undergo enlargement in every dockyard possessed by the Queen.

"We have in the whole of Her Majesty's yards 42 building slips, and at this moment only nine of them are large enough for the construction of first-rate ships. We are increasing the size of those slips, and, of course, a large amount of money is required for this purpose. Then, again, we have 33 docks, of which four only, in Her Majesty's yards, will hold our largest ships. We are obliged to alter those docks, and five of them are now being increased in size; but we cannot accomplish that without expending an immense amount of money."

After noticing these things, Sir JOHN informs us that the committee appointed to examine the state of the machinery in our dockyards, consisting of Admiral RAMSDEN, Mr. JOHN WARD, and Mr. JAMES NASMYTH—not an exceedingly well-selected committee, as we could show—reports favourably upon its condition, and con-

Digitized by Google

siders that the public money has been well expended in that respect.

"That committee has issued," said Sir John, "a most able report, containing several recommendations which it is the intention of the Admiralty to adopt, as we believe that they will tend to the advantage of the public service. One of those recommendations is that we should apply for tenders for the supply of engines much more largely than has hitherto been the case, and in pursuance of this recommendation we have thought it our duty to invite tenders from Liverpool, Scotland, and most of the eminent houses engaged in this particular business."

All this looks very well upon the face of it; but we are not quite sure that we shall not have occasion hereafter to give our readers a glimpse of something beyond the outward aspect of this matter. And we must say the same of the next committee to which Sir JOHN referred :—

"That committee was headed by Admiral Smart, and it has been engaged in the investigation down to the present time. The report is not yet finished, but I understand," said Sir John, "from the chairman, that the result of the inquiry will be the recommendation of very considerable changes, which, in his opinion, will lead to a much more economical and judicious expenditure in the dockyards in future. I mention this to show the desire that there is on the part of the Government to secure the most advantageous expenditure of the large sums intrusted to their care; and I trust that the comparisons which I have instituted between 1858 and 1852, will lead to the impression that in the expenditure of these sums we have been influenced solely by a sense of duty, and by a desire to exercise the utmost practicable economy."

We confess to some want of confidence in these plausible proceedings of the present First Lord. Will Sir JOHN give the proceedings and report of this latter committee to the public before he takes action upon it? We hope he will. If not he will run a great risk of doing vital injury to the public service, whatever his intentions may be. When small secret committees meet and investigate important affairs, great danger always exists, unless their counsels are unanimous. We shall watch the results in the present instance.

We must not enter here upon the proposals made by Sir JOHN PAKINGTON for increasing the Channel Fleet, and for replacing the sailing flag-ships on foreign stations with steam-ships, although we heartily approve of both. We hasten to notice his comparison between our steam navy and that of France :—

"We took means of ascertaining what were the facts, and we found that the line-of-battle ships of France were exactly the same in number as our own—viz., 29. The French had fewer three-deckers, first-rates, than we had, but of our 29 ships there were nine which were inferior to any of the French ones. Therefore, we must make up our mind to this, that in July last the screw line-of-battle ships of France were 29, and those of England also 29 in number; but that in point of power and efficiency the line-of-battle ships of England were, to the best of my knowledge and belief, inferior to those of France. The nine ships to which I have referred are sailing 80-gun ships, which have been converted into screw eighties, and consequently have not room for their engines, and are generally inferior ships."

We are strongly inclined to doubt the inferiority of the English line-of-battle ships to those of France. Numerically we were undoubtedly no stronger, to say the least, than the French. But, notwithstanding all that Sir JOHN states respecting our old 80-gun ships, we believe that "in point of power and efficiency" we were the stronger of the two. At any rate, we know perfectly well that many of the French steam line-of-battle ships are lumbering old craft, converted from sailing vessels of a very antique type, and deficient of many of the qualities essential to their general value and efficiency. But the question is scarcely worth discussing, for the bare approach to equality with us on the part of the French ought to incite us to renewed exertions. Sir BALDWIN WALKER, the Surveyor of the Navy, has always, it appears, been alive to our deficiency of line-of-battle ships, and has frequently made corresponding "submissions" to the Admiralty; but the demand for small vessels during the Russian war prevented the carrying out of his designs.

With regard to frigates, we are told, the case is still stronger against us. During the last ten years proposals were made for adding 37 frigates; the actual number built was only 23, so that there was a deficiency of 14 frigates in that interval.

"In the course of the autumn, I found" says Sir John, "that instead of being upon a par in point of numbers, as was the case with regard to line-of-battle ships, we were in a positive numerical inferiority of 12 frigates. The English navy comprises 17 screw frigates and nine paddle frigates, two receiving their engines and six building, making a total of 34. The French navy reckons 15 screws, 19 paddle-wheels, three receiving their engines, one converting, and eight building, making an aggregate of 46."

And with respect to block-ships, we learn that they are wholly useless. "They are good for nothing as sea-going men-of-war; they may be useful perhaps as floating batteries; but as men-of-war they are perfectly useless. Most of them are rotten, and they are very nearly worn out."

We now come to what the Admiralty are about to do towards the "re-construction" of the navy. And first let us note what our prospects were in 1859 :—

"We had four ships receiving engines, and during the year 1859 there were two new ships to be launched and one to be converted, which would have raised the number of our line-of-battle ships to 36. We found that the progress of the French navy was not to be at all in the same ratio. At the end of 1859, on the contrary, the comparison would have stood—England, 36 line-of-battle ships, with 3,400 guns, and 19,750-horse power, none of these ships being the inferior ones to which I have referred; France, 40 line-of-battle ships, with 3,706 guns, and 27,510-horse power."

To prevent our fleets occupying such relative positions as this, the Admiralty asked the Surveyor of the Navy what arrangements could be made to enable them, with the labour at their disposal, and without exceeding the estimates to which they were pledged, to increase the number of our line-of-battle ships. The result was, that they determined to withdraw from the ordinary building and repair of ships a force sufficient to enable them at once to commence the conversion of four three-deck line-of-battle ships —viz., the *Neptune*, the *St. George*, the *Trafalgar*, and the *Queen* into two-deck screw-ships, with 90 guns and 500 horse-power each.

"That was all we could then accomplish. Those orders were given in the month of August last; during the course of the winter these ships have been rapidly advancing to completion, and in the course of the spring they will be launched, and added to the strength of the British navy. In addition to these four ships we now propose to convert five others—viz., the *Lion* (which was ordered to be converted by the right hon. baronet opposite, Sir C. Wood, but with which no progress has been made), the *Nelson*, the *Royal William*, the *Waterloo*, and the *Rodney*. The *Nelson*, the *Royal William*, and the *Waterloo*, three-deckers, will, in the course of the ensuing year, be converted into ships of 90 guns, and the *Rodney*, at present a 90-gun ship, will be converted into a screw line-of-battle ship of the same class. I should have hesitated about the expediency of converting the *Rodney*, had not a sister ship of hers, the *London*, lately been so treated with great success."

Had no extraordinary exertions been made, only two ships would have been launched in the course of the year 1859, viz., the *Hood* and the *Revenge*, both of 91 guns; the *Hood* having 600, and the *Revenge* 800-horse power. Those who look at the returns of the navy, will see that there are included in them ten ships as in course of building. These would have been launched at different periods during the next few years, but the Admiralty have selected those which were the most forward, and therefore could be operated upon most easily, and with the least expense, and propose to launch four of them during the ensuing year. In all, therefore, there will be launched during the year six screw line-of-battle ships—viz., the *Hood*, 91 guns, and 600-horse power; the *Revenge*, 91, 800-horse power; the *Victoria*, 121, 1,000-horse power; the *Howe*, 121, 1,000-horse power; the *Duncan*, 101, 800-horse power; and the *Prince of Wales*, 131, 800-horse power.

We next come to frigates, the proposals with respect to which we will give in Sir JOHN's own words :—

"Our proposal is, as to frigates, instead of launching three, which is the usual number, each year, to hurry on two which are building, and so launch five this year. They will be the *Galatea*, of 26 guns and 800-horse power; the *Ariadne*, of 32 guns and 800-horse power; the *Bacchante*, of 50 guns and 600-horse power; the *Narcissus*, of 50 guns and 400-horse power; and the *Immortalité*, of 50 guns and 600-horse power. In addition to these we propose to convert four of the sailing frigates to which I have adverted—the *Phaeton*, *Severn*, *Sutlej*, and the *Phœbe*—to lengthen them amidships, at the bows, and at the stern. I believe these ships will become as efficient and as valuable as it is possible for converted ships to be. I fear they will be very costly ships, but still most valuable and effective, carrying the same armament they now bear—50 guns. The cost will be for the labour of conversion £42,000 for each ship, and the cost of engines of 500-horse power £30,000, so that each ship will cost about £72,000. If, however, we were to construct new ships of the same size they would cost at least each £40,000 more; and, moreover, these converted frigates can be added to our navy in a much less time than it would take to build new ones. We thus propose to add nine frigates in the course of the year."

On coming to the question of iron-cased vessels, Sir JOHN, naturally enough, became unusually serious. He spoke as follows :—

"I now have to beg the attention of the committee to a portion of this subject which is the most difficult, but upon which I am bound to be candid—I allude to the subject of iron-cased ships. In referring to the French navy I made no mention of what they were going to do in respect to those ships, but it appears that they have laid down at Toulon two vessels upon that plan, which are far advanced towards completion. They are to be about the size and tonnage of the vessel which they consider to be their finest line-of-battle ship, the *Napoleon*, upon which I understand they have been modelled. They are only to carry 30 guns, but those guns are to be of the heaviest calibre, and the vessels are to be coated with 4½-inch plates of iron or steel, it not being yet decided which metal shall be adopted. In this state of things the Government felt it to be their duty in the course of last summer to institute experiments as to the power of certain metal sheathing to resist shot. The committee will perceive that it would not be proper in me to enter into detail at present upon that subject and I can only say that the experiments were most carefully made with all varieties of metal and in all ways. In the course of the autumn, as every gentleman who reads the newspapers must know, some wonderful inventions were made in artillery, and it then appeared to me to be my duty to ascertain how far the previous experiments would be affected by the recent discoveries in artillery arms. The House will not expect me to give in detail the result of these experiments, but I am bound to say that it has convinced the Admiralty that, whatever be the cost, we have no option in the discharge of our duty but to commence the construction of these iron-cased ships. I shall not conceal from the House that they will be the most costly ships ever built for the British navy; but still, assuming—that of which I have no doubt—that our plans will receive the sanction of Parliament, we have resolved that it is our duty to lose no time in building at least two of these vessels. I am bound to say, also, that we feel it to be no less our duty to throw away no chance whatever in endeavouring to make these ships as effective and successful as possible. We have called upon the most competent parties in different parts of England connected with private trade to give us their designs and counsel. We have likewise called upon our officials in the dockyards—upon our able master shipwrights, of whom, I am glad to say, we have a considerable number—to furnish us with designs. The determination of the Admiralty is to leave nothing undone, to take every precaution that prudence and caution can suggest, in order that the large sums which these ships will cost shall not be thrown away. We are equally resolved at the same time to lose not a moment in bringing these ships into existence. They are the ships which appeared in our estimates under the head of ships to be built by contract. We have not room to build them in our dockyards. From the mode of construction which we propose we have no hesitation in confiding their construction, under our own superintendence, to those who will build them by contract; and by the close of the year upon which we are now entering, I hope these two ships may also be added to the strength of the British navy."

Our space is now exhausted, and we must therefore defer further observations until next week, only adding that the designs for the iron-cased vessels have this week been submitted to the Admiralty, and are now under examination. They are very varied in their character, and some of them are for vessels of extraordinary dimensions.

ROYAL NAVAL ENGINEERS.

IN reading through the lucid statement of Sir J. PAKINGTON, made to the House of Commons on Friday last, we were somewhat surprised that not even a passing notice in the reforms there shadowed forth has been accorded to the Naval Engineers, although we believe that a memorial from that valuable portion of our scientific branch of the navy has been some time in the hands of the authorities. We should have imagined that, with eyes now open to the strides made by our friends on the opposite side of the channel, where the Emperor has seen the imperative necessity of giving to those officers their proper status, some such course would have

Digitized by Google

been adopted by our enlightened First Lord. We are not unaware of the prejudices existing in the minds of some few, high in authority, who, looking with aversion on that power which has now become universal, would commit the Naval Engineer to the doom of Frankenstein—who created a monster but for his own annihilation. But we will not pause to oppose such prejudices. Ours is now about to become wholly a steam navy, and the naval engineer *must* have ceded to him, however unwillingly, a position becoming the man who has to preserve and control those complex and expensive giants over which it is his business to preside.

In the earlier volumes of this Magazine (Vol. 37, p. 201, for 27th August, 1842, for example), we were the first to initiate a movement for the improvement of the naval engineers. Our remarks were then approved by our contemporaries, and obtained extensive publicity in the journals of the day. The royal steam navy at that period (1842), was but the germ of that which has now attained a monster growth, and is about to have a new era inaugurated. The steam vessel in those days was the exception; now it has gone forth that the entire navy, in its "reconstruction," is to be independent of that changeable element, the wind, and will, as Homer prefigured, be "self-moved instinct with mind."*

In November, 1846 (vol. 45, p. 503), we were enabled to announce to our readers that the naval engineer had commenced to move towards his proper position, their lordships "having decided on promoting several of this valuable class of officers to ward-room rank." On the 27th of February of the succeeding year, an Order in Council was obtained upon which was based the circular dated 1st April, 1847 (given entire at p. 597, vol. 46), constituting the naval engineer, or chief engineer of the new establishment, a commissioned officer, ranking with lieutenants and masters, whilst to the "assistant engineer" was offered a rank co-equal with second masters. Ere ten years had elapsed, it was found that these partial and grudging recognitions of the claims of the naval engineer did not give satisfaction, and at the breaking out of the Russian war our force of "naval engineers" was so low that labourers and others from our various railway establishments were inducted at once into the service of Her Majesty, and that at a higher rate of remuneration than had been assigned to many of the most intelligent of the chief engineers—men of many years' servitude and of great experience. To remedy a defect so glaring, on the 4th of April, 1856, another Order in Council was laid before Her Majesty, and graciously approved of, in which full-pay, half-pay, pensions, and allowances were to be accorded to the naval engineer; and he, being admitted to "now form a most important class in Her Majesty's navy," was to be placed in every respect upon a footing with masters of the fleet, masters, and second masters respectively. A proviso was also therein introduced for the settlement of the claims of those who "were not considered qualified for promotion to a higher class from want of education," the same document proceeding afterwards to take such from serving under a chief engineer—to keep down the number of which class (the chief engineers) is stated to be "in every point of view most desirable." Upon this document was based the last circular, ceding half-pay, and giving full-pay according to servitude, as given to masters.

The extra time, however, allowed to count for full-pay when served as second masters in the last-mentioned class, has never been accorded to the naval engineer, whose time served as first-class assistant (if not his entire time) should also count. Neither has he any allowance for the charge of stores, as has the master, with whom it was stated to be desirable to assimilate him. We would, however, urge on Sir JOHN PAKINGTON, in his contemplated changes, the necessity of placing of the naval engineer on a similar footing to the surgeon, the whole of whose time of servitude counts. The engineer and the surgeon should be co-equal, as they now are in the French navy. They should be equal in education, of course, as well as in position, and if they are not the fault lies with the Admiralty, who admit those of so low a standard. The assistant engineer also, as the assistant surgeon, enters the service after the study of his profession has been obtained, each wanting but the requisite experience procurable by practice alone, whilst the other branches of the service are initiated into their duties at the expense of the public purse. We do hope that in the changes contemplated the naval engineer will have such a position given him as will show that class interests are not unfairly studied, and as will put an end to those idle bickerings which stay the progress of improvement, and prevent the attainment of that efficiency which our great naval reformer, Sir JOHN PAKINGTON, professes so earnestly to desire.

* In Pope's translation of Homer's Odyssey, Eighth Book, in the description of the Fleet of King Alcinous, occurs the following:—

"So shalt thou instant reach the realm assigned
In wondrous ships, self-moved, instinct with mind."
* * * * * *
Though clouds and darkness veil the encumbered sky,
Fearless through darkness and through clouds they fly.
Tho' tempests rage—tho' roll the swelling main—
The seas may roll, the tempests swell in vain.
Eley the stern god that o'er the waves preside,
Safe as they pass, and safe re-pass, the tide),
With fury burns; while careless they convey
Promiscuous ev'ry guest to ev'ry bay."

OUR STEAM NAVY.

THE return to the order of the House of Commons, setting forth the progress and present condition of our steam navy, strikingly confirms the figures given in the paper read at the Society of Arts in December last. The total number of line-of-battle ships is there stated to be 49. In the paper mentioned the number given was 51. The small discrepancy probably arises from the official return excluding two ships, the conversion of which into screws has been decided upon, and perhaps commenced, but not far advanced. Of frigates the return gives 25; whereas the paper gave 28. We account for this difference by supposing that in the return the *Ariadne*, *Galatea*, and some other vessel have been set down as corvettes. This seems certain when the next classes of vessels are compared, viz., corvettes, sloops, and "small vessels;" for while the official paper gives 50 of these, the Society of Arts paper gave but 48. Taking frigates, corvettes, sloops, and small vessels together, we get a total of 75 from the one paper, and 76 from the other. The number of gunboats is 161 in the official paper, and 163 in the other. Precisely the same numbers of block ships, mortar vessels, floating batteries, and gun vessels, are given in both papers. Taking the whole of the screw fighting vessels of all classes (from which tenders, troop ships, store ships and yachts are excluded) we get the number 333 from the official return, while the number given in December was 331. These discrepancies are not worth mentioning, except as they illustrate the general correctness of the figures. Such as they are they very likely arise from the indisposition of Sir CHARLES WOOD to appear even to exaggerate the number of ships provided during his term of office. In dealing with the official table (next page), care must be taken to add the numbers in the first and third numerical columns, in order to get the total number of screw ships afloat, building, and undergoing conversion; and *Fighting-vessels* only are to be considered.

ANOTHER NOVELTY IN ARTILLERY.

ARTILLERY, which is already a very powerful arm of the service, seems destined to altogether supersede and overwhelm the minor missiles of the sister service. Last week we gave some account of a gun apparently unparalleled in range, lightness, and application to ships and sea-coast garrisons. This week, we have to notice a perfectly novel LIGHT FIELD PIECE, with carriage and ammunition waggon; the whole being the invention of a young officer of the Bengal Artillery now in England. If it succeed—and we at present see no valid reason why it should not—it will be likely not only to supersede the whole present system of field-guns, and especially that of the horse artillery, but also to reduce the *cost* of that most expensive branch to little more than one-half of what it is at present, while making it even more efficient.

We are in a position to say much regarding this invention, but must refrain from doing so, because the inventor has already submitted his proposal, first to the Commander-in-Chief in India, where a 9-pounder was given him by Lord CLYDE for experimental purposes (the report of the success of which, we believe, he now has with him), and recently, to Lord STANLEY, the head of Indian affairs, to whom of course he was bound to refer it, and who, we doubt not, will give it that attention for which he is so justly celebrated, and which it well deserves. We must not, therefore, anticipate the inventor's statement to the Government, by giving publicity to a description of the new weapon, which he, as a dutiful servant, is bound to submit to them in the first instance. But we may, as some exemplification of the *tendency* of this invention, ask our professional—and especially military—readers, what they would think of half-a-dozen weapons throwing 9-lb. shot, or 24-lb. howitzer-shell and canister, in the hands of a regiment of our dragoons, and advancing with them at a gallop to the *very feet* of a square or line of infantry, throwing their deadly missiles into them without cessation from their line of advance, and without checking for an instant the headlong gallop which is shortly to convert their murderous fire into an actual charge, and leave the cavalry which accompanies them nothing more to do than to ride into the gaps which they have made!

A gun with which this might be done, and an ammunition box, apparently impenetrable by antagonistic round-shot of extreme simplicity of construction, and holding no less than five times the number of rounds of the present complicated boxes, constitute the principal points of this officer's invention, of which he has a model in London. We hope before long to give our readers a full description with illustrations.

NEW COMMITTEE ON NAVAL ORDNANCE.—Captain Caffin, C.B., Naval Director-General of Artillery, on Tuesday visited Woolwich Arsenal for the purpose, it is said, of making arrangements with the officers of the select committee for investigating and carrying out the new principle proposed for the armament of the fleet. A special committee of some of the most able and scientific officers of Her Majesty's service has been appointed, of which the following names have transpired, namely:—Rear-Admiral Sir Thomas Hastings, K.C.B., as chairman; Sir John Burgoyne, Bart., G.C.B., Royal Engineers, Inspector-General of Fortifications; and General Sir Howard Douglas, Bart., G.C.B., G. C. M. G., 15th Foot. Captain Caffin to act as secretary to the committee.

CAPTAIN NORTON'S INVENTIONS.—At the request of several of the officers of the Royal Engineers at Brompton Barracks, Captain Norton has just completed another series of experiments at Chatham, for the purpose of subjecting some of his inventions to a severe test, in order to prove their practical utility, his former experiments having attracted a high degree of interest among scientific persons, and the officers of the Royal Artillery and Royal Engineers. The experiments were quite successful.

OUR STEAM NAVY.

Return to an Order of the Honourable the House of Commons, dated 11th Feb., 1859.

Returns of the number of Steam Ships and Vessels, added to the Navy in the year 1848, and each subsequent year, divided into Ships of the Line, Frigates, and other classes of vessels, and distinguishing those which have been built, converted, and purchased; with the total of each class in each year, and grand total in all the years.

And of the number of Steam Ships and Vessels in the Navy afloat, and building or converting, on the 1st Jan., 1859, divided into Ships of the Line, Frigates, and other classes of vessels, and distinguishing screw and paddle-wheel vessels.

STATEMENT SHOWING the NUMBER of STEAM VESSELS ADDED to the NAVY in the FOLLOWING YEARS:—

		Grand Total.	Ships of the Line	Frigates	Block Ships	Mortar Ships	Corvettes and Sloops.	Floating Batteries.	Gun Vessels	Gun Boats	Troop and Store Ships.	Tenders, &c.	Totals

Parliamentary Proceedings.

CONDENSED FOR THE "MECHANICS' MAGAZINE."

THURSDAY, FEBRUARY 24.

HOUSE OF COMMONS.

THE WORKS AT LONDON BRIDGE.

In answer to General Codrington the First Lord of the Admiralty said the Board of Admiralty had given its official sanction to the construction of the permanent works now being made beneath the southern arch of London-bridge about the end of March last, since which time he had the honour of receiving a deputation on the subject, but on due consideration of the arguments advanced, he had not thought fit to alter his decision.

FRENCH VESSELS AT SPITHEAD.

In answer to Sir C. Napier,

Sir J. Pakington said he had received information from Portsmouth that two or three nights ago a French vessel, an aviso, with two cutters, had anchored at Spithead; that during the night the aviso got under way, and that she was at anchor again in the morning; but whether she took soundings or not in Stokes' Bay he was not in a position to state. Those vessels had been constantly up and down all parts of the coast of England, and they were engaged in the protection of the French fisheries. That was the ground on which they were constantly in our waters. They had also anchored in Portland Roads under similar circumstances. He was not aware whether anything particular had been done upon this occasion, but these vessels had been for a considerable time hovering about the coast of England.

Sir C. Napier asked if the aviso had more than her usual complement of officers on board.

Sir J. Pakington was not aware whether she had on board more than her proper number of officers.

STATE OF THE NAVY.

Sir C. Napier moved the return of the number and actual condition of the several classes of ships of war and steamers, and of the ships built and broken up since 1815.

Sir J. Pakington objected to the return that it would be very expensive, and of little use, as it could not possibly be prepared before the discussion on the navy estimates, when he hoped he should be able to make a statement that would be satisfactory to the gallant admiral and the House itself.

Sir C. Napier believed the Admiralty could give the return with the greatest facility. All he wanted to know was the exact state of the navy.

Admiral Duncombe hoped the gallant admiral would not press for the return.

The motion for the return was then negatived.

AGRICULTURAL STATISTICS.

Mr. Caird, according to notice, moved the following resolution:—"That it would be advantageous to the public interests that the Government should ascertain and publish periodically the agricultural statistics of Great Britain, in so far as they relate to the extent of acres under the several crops of corn, vegetables, and grass."

After numerous speeches the House divided, and the numbers were,

For the motion	152
Against it	163
Majority	—11

The motion was therefore lost.

BLEACHING AND DYEING WORKS.

Mr. Crook moved for leave to bring in a Bill to place the employment of women, young persons and children, in bleaching and dyeing works under the regulations of the Factories Act.

The Bill was strongly opposed by Mr. Kirk, Mr. M'Carthy, and Mr. Turner, as impracticable, unnecessary, and contrary to the general opinion of the Select Committee that reported on the subject.

Mr. Packe thought the Bill premature.

Mr. Corbett thought the House should allow the Bill to be brought in.

Mr. Richardson believed that the employment of women and children in bleach-fields was gradually on the decrease, and that legislation was altogether unnecessary.

Mr. Labouchere hoped that the House would be favoured with the views of the President of the Board of Trade on this subject.

Mr. Henley said, this vexed question had been discussed for the last three or four years. It had been sent to a committee, which sat upon it for a great part of one session, and for some part of another. The members were divided in the proportion of seven to five on the main question, and after taking evidence decided against any immediate legislation. They ought at least to wait and see whether the recommendations of the committee produced any effect upon the trade.

Mr. Chpetham, as a practical man, opposed the motion.

Lord J. Manners believed the time was not ripe for the introduction of a Bill like this.

Mr. Pease held that the operatives had the first claim on the sympathies of the House; and all the arguments now adduced with respect to the peculiarity of the bleaching trade had been urged over and over again against the regulation of factory labour. He should have been glad to see legislation adopted in this case.

Mr. Greer said there had been no complaint from the operatives engaged in the bleaching works of Ireland.

Mr. Crook replied, expressing his determination to take the sense of the House.

The House then divided, when the numbers were:—

For the motion	30
Against	108

FRIDAY, FEBRUARY 26.

HOUSE OF COMMONS.

PRINTING OF THE BIBLE.

Mr. A. Black asked whether it was intended to renew the patent for printing the Bible and Acts of Parliament, which expires in January next; and, in the event of the patent not being renewed, whether the right of printing the Bible in England was to be limited to the two Universities, or to be thrown open; and if any other arrangement would be made for printing the Acts of Parliament.

Sir S. Northcote said the whole subject was under the consideration of the Government, and he could give no answer.

HARBOURS OF REFUGE.

In reply to Mr. Garnett,

Sir S. Northcote said the report of the Commissioners would be laid on the table before the end of next week.

THE ATLANTIC TELEGRAPH.

Mr. Wyld asked whether the Government intended to grant any guarantee to the Atlantic Telegraph Company.

The Chancellor of the Exchequer said the Government had come to a resolution to grant no guarantee except on conditional terms. Since then the company had made another application, to which the Government had responded in the sense of the rule which they had laid down for themselves, but whether the company had accepted the assistance of the Government on the conditions on which it had been offered he was not prepared to say. Any assistance which the Government might afford to that company, or to any other, would be on the condition that the line was in a working state.

THE NAVY ESTIMATES.

For the debate on this subject see p. 149.

MONDAY, FEBRUARY 28.

HOUSE OF COMMONS.

ATLANTIC TELEGRAPH COMPANY.

Mr. Moffatt asked the Chancellor of the Exchequer whether any guarantee had been promised to the Atlantic Telegraph Company; and, if so, whether he was prepared to state the nature and terms of that guarantee. He also wished to know whether the United States' Government were parties to the guarantee.

The Chancellor of the Exchequer said the Atlantic Telegraph Company originally required an unconditional guarantee, which the Government declined to give; but recently the Government offered to give them a guarantee upon certain conditions. Those conditions, he believed, were still under the consideration of the Atlantic Telegraph Company.

Mr. S. Wortley asked whether the Chancellor of the Exchequer had any objection to state whether or not the Government, before offering to give any assistance to the Atlantic Telegraph Company, asked them to surrender the exclusive right of laying marine cables along the coast of Newfoundland.

The Chancellor of the Exchequer said the Government did ask for such surrender.

TUESDAY, MARCH 1.

HOUSE OF COMMONS.

SHIPPING INTEREST.

Mr. Lindsay moved the appointment of a select committee to inquire into the operation of certain burdens and restrictions specially affecting merchant shipping.

Mr. Liddell seconded the motion.

Mr. Crawford moved, as an addition to Mr. Lindsay's motion, the following words, "and of the following statutes, 9 and 10 Victoria, cap. 93, an Act for compensating the families of persons killed by accidents; the Merchant Shipping Act, 1854; the Merchant Shipping Act Amendment Act, 1855; the Passengers Act, 1855; and the Chinese Passengers Act, 1855."

Mr. Collier seconded the amendment.

After remarks from Mr. Horsfall, Mr. Labouchere, Sir S. Northcote, Mr. Fenwick, Mr. Clay, Mr. Ingham, Mr. Ridley, Mr. Cardwell, Mr. Henley, Mr. Adams, Mr. J. Wilson, and Mr. Speight, the motion, with Mr. Crawford's addition, was agreed to.

The Admiralty Tables.—A periodical has this week reprinted the Admiralty Tables which were published three weeks ago in our Supplement, accompanying them by the following announcement: "The Committee on Steam Ship Performance, having recently memorialised the Admiralty, and the prohibition to the publication of the two sets of tables just referred to having been removed, we are *now* enabled to present to our readers, &c." We can only pity the man who could take the pains to pen such a very ingenious but misleading sentence. Suffice it to say, the Committee referred to took no effective part in getting the Admiralty restriction removed from the tables, but were very glad indeed to receive them from us after we had gained their Lordships' consent. We take no credit to ourselves in the matter beyond that of *knowing how to ask for them properly*: but we grieve to see a man embracing a privilege which we have obtained for him, and then thanking others for the boon. Has he no friend to tell him what is just in such a case?

LONDON FIRES IN 1858.

TWENTY-EIGHTH ANNUAL REPORT.

By Mr. WM. BADDELEY, *C.E., Inventor of the Portable Canvass Cisterns, Farmers' Fire-engine, Improved Jet-spreaders, &c.*

"The statistics of London fires are by no means devoid of interest, and the time may come when they will form an index to the social advancement of the people; for, in proportion as houses are built more and more fire-proof, and habits of carefulness become more and more diffused, the number of destructive fires will assuredly lessen."—*Knight's London.*

"IF our own business is concerned," observes a recent writer,* "when the next house is on fire, that business must be pretty generally extended in the Metropolis, where no fewer than one thousand one hundred and fourteen fires occurred last year."

This number, singularly enough, is just one less than in 1857, so that, having regard to the increase of population and of buildings, the actual decrease may be considered as decidedly satisfactory. The general character of last year's fires, however, is described as "more serious than usual, entailing very severe labour and watching on the part of the firemen."† The casualties have also been unusually heavy.

The number of *totally destroyed*, 32, is the same as in the previous year; the number of *seriously damaged* is 385, and of these 85 were "all but destroyed;" the number of *slightly damaged* is 697. Of course, these numbers only relate to those fires which have come to the knowledge of the firemen, and are officially recorded. From what is known, however, it is probable that the total number of fires, where slight damage only is done, greatly exceeds the whole of those which are reported.

Of last year's fires, one was self-extinguished; 300 were extinguished by the inmates of the premises without assistance; 376 were extinguished by casual aid; and the extinguishing of 437 devolved upon the firemen.

Parish engine-keepers are reported to have rendered efficient services at 104 fires, but this does not convey an adequate idea of their real usefulness; services which have been considered worthy of pecuniary reward by the officers of the Fire Brigade being frequently unreported.

The following table shows the monthly distribution of last year's fires, with their fatalities, &c.

The total number of chimneys on fire (a very large one) is not reported, but only those which were said to be "fires," and attended as such.

Months.	Number of Fires.	Chimneys on Fire.	False Alarms.	Fatal Fires.	Lives Lost.

The Royal Society for the Protection of Life from Fire was first established in 1836, but its objects were not fully developed, nor its operations carried to any extent until 1843, when the necessity for, as well as the utility of such an Institution became so apparent, that the Society was re-organised, and placed upon a permanent footing, and from that time its course has been progressive and prosperous. Commencing with six fire-escape stations, they have now 67, extending over all parts of London (with but few intervening vacancies) at half-mile distances from each other, each attended throughout the night by an efficient and well-trained conductor. During the past year 504 fires have been attended, and 57 lives rescued from burning buildings by the Society's servants, as shown by the following statement:—

Date.	Place.	Conductor's Name.	Lives saved
Jan. 2	Clerkenwell-green	Robinson	2

Dec. 6	123 Old-st., St. Luke's	Passmore ...	1
			57

The following twelve additional stations have been established during the past year, viz.:—

1. Green Man Gate, Old Kent-road.
2. Tooley-street, near Bermondsey-street.
3. Ratcliffe, in the Commercial-rd., by the railway-arch.
4. Mile-end-road, opposite Messrs. Charringtons' brewery.
5. Limehouse, corner of the Commercial and East India-roads.
6. St. John, Wapping, in front of the church.
7. St. John's Church, Bethnal Green.
8. Bishop's Road, facing Trinity Church.
9. Kensington, in the High-street.
10. Notting-hill, near the gate.
11. West Brompton, by the Consumption Hospital.
12. Tower-hill, by the Mint.

The Royal Society acknowledge with great satisfaction the cordiality which continues to exist between the firemen of the London Brigade and the Society's conductors, as well as the hearty co-operation of the City and Metropolitan police.

The number of *fatal fires* is two more than in the preceding year, but the number of lives lost is, from peculiar circumstances, unusually large. The fatal fires may be classed under the following heads:—

	Fires.	Lives lost.
Personal accidents from the ignition of wearing apparel or bedding	4 ...	4
Ditto ditto from intoxication.	3 ...	3
Killed by explosion of firework manufactory.	1 ...	4
Inability to escape from burning buildings ...	8 ...	27
	16	38

Of these fatal fires, the following require a passing notice:—

Monday, January 11th, 3¼ A.M.—The premises of Mr. Smith, coffee-shop keeper, 49 Gray's-inn-lane, were discovered, by a police-constable, to be on fire. Several families were in the house at the time, and on the alarm being given, all but two persons effected their escape. Conductor Horne, with the Royal Society's fire-escape from Bedford-row, was promptly in attendance; he immediately ascended to the third floor, and went to the back room, where he found Mr. and Mrs. Odder; both were very aged, and the former bed-ridden. Mrs. Odder had her husband round the neck and would not leave him; while endeavouring to separate them the flames rushed into the room and enveloped the three persons. Conductor Horne threw himself out of the back window and fell upon a lead flat, where he was found and rescued by Conductor Arkell. Horne was so dreadfully burned about the head and hands, that he was taken to the Free Hospital, Gray's-inn-lane, and it was many months before he was sufficiently recovered to resume duty. The origin of the fire could not be satisfactorily ascertained, but it appeared to have begun in the back parlour, and very soon ascended the staircase.

Wednesday, March 17, 2¼ A.M., a fire broke out in the house of Mr. Dullins, foreign merchant, at the corner of Devonshire-street, and Devonshire-square, Bishopsgate-street; the first alarm was given by a police-constable, who saw a dense column of black smoke issue suddenly from one of the chimneys. Conductor Eilbeck, with the Royal Society's fire-escape, was immediately in attendance, and placing his machine to the second floor window, brought down Mr. Dullins and Mrs. Graff, the housekeeper. The only other inmates of the house were Mr. and Mrs. Ampsell, who only moved in the evening before, and were sleeping on the third (attic) floor. Mrs. Ampsell was roused by the cries of "fire," and awoke her husband; finding it was impossible to go down stairs for the smoke, they returned to the attic, and Mrs. Ampsell got out of window, but her husband was overpowered by the smoke and fell just within the window, where he was afterwards found quite dead. After he had rescued Mr. Dullins and his housekeeper, Conductor Eilbeck ascended to the attic window, but could not enter for the dense black smoke which poured from it, and which he recognized as the product of burning naptha or turpentine. The person of Mrs. Graff was quite black, and her hair was saturated with the vapour of turpentine, a large quantity had been inhaled by her, and she was for a long time an inmate of the German Hospital. The fire was found to have commenced in the lower part of the premises, which had been saturated with turpentine. At the coroner's inquest it was stated that the Union fire-office had an insurance on the stock, in the name of Dullins and partner, for £2,400. In November previous, Mr. Dullins cancelled a policy in the Manchester fire-office for £1,200, and took out a new one for £2,200. At the same time Mr. Graff effected an insurance in the Sun fire-office for £1,200, he having no property to represent such a sum in the premises at the time of the fire. Mrs. Graff stated at the inquest that her husband left for Holland about three weeks before the fire; she did not know his business! The only property he had on the premises was a small quantity of furniture that Mr. Dullins had paid for. After three lengthened sittings the jury returned the following verdict—"That the deceased lost his life at the fire that occurred at the house, No. 17 Devonshire-square; and though there is no proof as to the origin of the fire, yet the circumstances connected with it, we (the jury) think are of a very suspicious nature."

Sunday, March 28th, 2¼ A.M.—The most fatal fire that has for many years occurred in the metropolis, broke out in the lower part of No. 20 Gilbert-street, Bloomsbury, occupied as a carpenter's workshop. A private passage led to the upper part; the first floor (two rooms) was occupied by a family named Eastwood, consisting of father, mother, and three children; on the second floor there were two families, the front room being occupied by Mr. and Mrs. Smith and nine children; the back room was tenanted by Mr. and Mrs. Hedger, and two adult sons. The fire was discovered by a police-constable named Sullivan, who gave an alarm, and was quickly joined by police-constable Soar; procuring a short ladder from a building opposite, they got out Mr. Eastwood and his family. One of Mr. Smith's sons threw himself from the second floor window and was fatally injured; none of the other inmates were seen alive. Although the Royal Society have for many years had a fire-escape stationed at Bloomsbury Church, within three minutes' run of the fire, no alarm was given there for twenty minutes; the consequence was, that on the conductor's arrival the house was enveloped in flames, and an entry impossible. A similar delay took place in calling the fire-engines, so that very shortly after their arrival the building fell to the ground, burying in a mass of *débris*, fire and smoke, no less than fourteen persons. An inquest was held on the bodies before Mr. Wakley, the coroner, which from the great excitement resulting from so lamentable a loss of life, was expected to lead to something useful. A post-mortem of the bodies, by direction of the coroner, led to the propounding of a fanciful theory by Mr. Rogers, lecturer on chemistry, who attributed the death of the parties to the inhalation of arsenical fumes given off from a cabinet of minerals in the adjoining building; Mr. Bennett, Surgeon to St. Giles's Infirmary, endorsed this singular notion. It was proved, however, that the minerals in question were not acted upon by fire, until long after the deceased had ceased to live; and that, so far from any poisonous vapours having penetrated through the wall and acted injuriously on human life, several persons were engaged in saving property in the room where the minerals stood, without feeling any inconvenience from such vapours. After several sittings, the real object of the inquiry was lost sight of, and it degenerated into a personal squabble between landlord and tenant; the patience of the jury became at last exhausted, and they precipitately closed the inquiry on the 5th of May, returning a verdict "That the deceased persons were found dead in the ruins of a certain house which had been destroyed by fire, but in what part of the premises, and by what means the said fire was caused they have found it impossible to discover." A very able report was prepared and submitted to the jury by Mr. Marsh Nelson, on the laws relating to the construction of buildings, the overcrowding of lodging-houses, the management of fire-engines, &c., suggesting the placing in more immediate connection police-stations, fire-engine and fire-escape stations, and the supply of water in case of fire; the whole of such establishments throughout the metropolis and its suburbs being rendered instantly available for public service in case of necessity by means of the electric telegraph.

Monday, July 12th, 6½ P.M.—While Mrs. Bennett (better known as Madame Coton), a young woman, a little girl, and two little boys, brothers, were engaged in the manufacture of fire-work, in the premises No. 4 Elizabeth-place, Westminster-road, the coloured fire suddenly, and spontaneously, ignited, and a fearful explosion was the result. A great number of persons passing at the time were more or less injured, four persons fatally; these were Mrs. Bennett herself; John Murray, aged 40, who in a state of intoxication attempted to enter the burning premises, and was blown from the first-floor window; a girl named Caroline Bridges, 11 years of age, who was standing in the road when the explosion took place; and Ann Williams, also 11 years of age, who had been sent on an errand, and in returning home called at Mr. Gibson's, No. 2 Melina-place, opposite to Mrs. Bennett's; some of the rockets from

* The *Standard*. † Mr. Braidwood's report.

Digitized by Google

Mrs. Bennett's flew into Mr. Gibson's house (he also being a fire-work maker), and set fire thereto, when the girl Williams was burned to a cinder. Mrs. Bennett's premises were all but destroyed by fire and explosion, and seven other buildings seriously damaged. At a coroner's inquest, the jury returned a verdict, "That the deceased died in consequence of burns received from an explosion at a fire-work manufactory in the Westminster-road, on the 12th ultimo, carried on by William Bowyer Bennett; and the jury therefore find a verdict of manslaughter against the said William Bowyer Bennett, for having unlawfully carried on such manufactory, contrary to the 9th and 10th William III. c. 7." Mr. Bennett was then committed for trial at the Central Criminal Court, bail being accepted for his appearance. On the 18th of August, Mr. Bennett surrendered to take his trial for the manslaughter of Caroline Bridges. The facts having been given in evidence, Mr. Giffard submitted "that there was no evidence upon which the jury could return a verdict to constitute the crime of manslaughter. It must be shown that the person so charged had committed an act, or omitted to act, the result of which had caused death." Mr. Justice Willes said, "it was a case for the jury. The fact could not be hidden that this was a question whether trades of such a character, imperilling as they did the lives of the public, could be said to be properly carried on, when it was found that such boys as those who had been examined were engaged to work at them. It made him shudder to think of the danger which existed to those who passed along." Mr. Giffard, in a very able speech, contended that there was neither act nor omission on the part of the prisoner to render him liable to conviction. The jury acquitted the prisoner, who was, on the following morning, again arrainged for the manslaughter of Ann Williams. After some discussion, it was agreed that Mr. Justice Byles should direct the jury to find a verdict of guilty, under the Act of William III., subject to appeal. In November following, the case came before the Criminal Court of Appeal, when the Court quashed the conviction.

Tuesday, July 27th, 1¼ A.M.—A fire broke out in the premises of Mr. Saunders, carver and gilder, Foley-street, Portland-place. The fire commenced in the apartments of Mr. Mason on the second floor, from a candle left burning. Three families were in the house at the time; Mr. and Mrs. Saunders, aged people, slept in the third floor front room, their son in the third floor back. The young man being roused by the smoke got out of window, and climbing up a water-spout reached the roof, when he commenced removing the tiles over the front room, and made a noble but unsuccessful attempt to save his parents. The fire-escape from Portland-road was promptly in attendance, but the flames pouring from the windows set fire to it and prevented the building from being entered, until the heat had been reduced by the working of the engines. Mrs. Saunders was then found dead from suffocation in the third floor front room, and Mr. Saunders in the back room nearly suffocated, but on removal to the hospital he recovered.

Sunday, September 12, 4 A.M.—A fire broke out in the premises of Mr. Roper, corn chandler, Royal-hill, Greenwich. The fire was discovered by Mr. Roper, who effected the escape of himself, his wife, an infant, and the nurse from the first floor back window. A servant girl and two young children were sleeping in the attic; the girl was woke by the heat, and in opening the door saw the flames coming up the staircase; without closing the door she rushed to the window and got on to the roof, from whence she was rescued by Smart, the fire-escape conductor; but the flames issuing from the window made an entry impossible, and after the fire was extinguished the two children (daughters, aged five years, and 15 months) were found burned to a cinder in the fallen débris on the basement. An inquest was held upon the bodies before Mr. Cartar, the coroner, when it appeared that after the fire Mr. Roper had sent in a claim to the Kent Fire-office, in which he was insured for £300, for goods amounting to £483; many of the articles were put down at excessive values, and were afterwards found to have been removed from the premises a few days previous to the fire. The servant girl also deposed to having been sent for turpentine the night before the fire, and the whole affair seemed so full of suspicion, that after numerous sittings the jury found "that Isabella Caroline, and Eliza Jane Roper, on the 12th of September, 1858, were burned to death in the house No. 8 Royal-hill, Greenwich; but how, or by what means the said fire originated, there is not sufficient evidence to prove. The jury cannot return this verdict without expressing their decided conviction that the origin of the fire is involved in great doubt and mystery, and grave suspicions exist in their minds that the fire did not result from accidental circumstances, and it is only from the want of strict legal evidence that the jury feel compelled to return this open verdict." Mr. Roper had, however, been charged at the police court with arson, and after numerous hearings was on the 12th of November committed for trial at the Central Criminal Court. On the fifth of January following, Mr. Roper was tried upon an indictment which in the first count alleged the capital offence of having feloniously and maliciously set fire to a dwelling house, a person being therein at the time; and in two others, the lesser offence of committing the same act, with intent to defraud the Kent Insurance Company. After a lengthened inquiry, the jury returned a verdict of "Not Guilty" on the first count, and it was considered unnecessary to proceed with the second indictment.

Friday, September 24th, 11½ P.M.—A fire broke out in the premises of Mrs. Harvey, dealer in china, Queen's-road-east, Chelsea. Pending the arrival of the fire-escape, police constable Pither obtained a ladder and entered the second floor back room, where he found Mr. and Mrs. Higginson; the constable got hold of Mr. Higginson, but he got away and threw himself out of the window, and sustained a concussion of the brain, which caused death. The constable then laid hold of Mrs. Higginson, but she struggled violently, and also got out of the window and fell, by which she was seriously injured. The coroner's inquest returned a verdict of "Accidental death."

Monday, December 6th, 2¼ A.M.—A fire took place in the house of Mr. Pond, coffee-house keeper, 122 Old-street, St. Luke's. At the time stated a police constable on the opposite side of the street had his attention called to the house by a sound like falling crockery-ware, and at once saw it was on fire; he immediately sprang his rattle, and knocked at the door to arouse the inmates, but received no answer. A ladder was brought from the police-station adjoining, and an unsuccessful attempt made to enter the first floor window. Conductor Passmore, with the Royal Society's fire-escape, was in front of the building in a few minutes, but the issuing flames fired the escape, and it was evidently impossible to enter the house. Hearing cries from the roof of the police-station, he ascended, and there found Mr. Pond, who told the conductor that his wife and daughter were in the burning building. After the fire was extinguished the mother and daughter were found dead near the fire-place in the third floor front room. At the inquest Mr. Pond stated that on being alarmed he placed a chair upon a table beneath the trap door leading to the roof, and got out, whilst holding his wife's hand to pull her up, a rush of hot air came up the staircase, and overpowered them; he fell backwards on the roof, his wife and daughter rushed towards the front window, but being overtaken by the smoke and heat, fell where they were found. The most extraordinary circumstance was, that both of the females were fully dressed, with garters, boots, and stays completely laced up, and in Mrs. Pond's stays was found the sum of twenty-three pounds; in her pocket was a portmonnaie with twenty shillings in silver, and some other trifling things. The jury returned a verdict that the deceased persons met their death by suffocation and burning, owing to a fire breaking out on the 6th of December; but how the said fire was caused there was not sufficient legal evidence to prove.

Thursday, December 30th, ½ A.M.—A fire broke out in a small four-roomed house in London passage, Upper Whitecross-street, occupied by Mr. Wrench, a cane-dresser, who carried on his business in the back room ground floor, and front room first floor, in which a quantity of oily cane shavings had accumulated, and which were of a highly inflammable character. Mr. Wrench, on smelling fire, ran down stairs, and found the back room in flames; he returned to the sleeping room, and rescued two of his children, when the flames spread so rapidly as to cut off all communication with the other inmates, and the house became a mass of fire. Conductor Passmore, with the Royal Society's fire-escape, as well as the fire-brigade with their engine from the Whitecross-street station, were very quickly in attendance, and every possible attempt made to rescue the inmates, but without avail. After the fire was extinguished, Mrs. Wrench was found sitting by the front window with her infant daughter in her arms. Their eldest son, Charles, aged nine years, was found in the back room first floor burned to a cinder. At the coroner's inquest the evidence went to show that this fatal calamity was the result of some undiscovered accident, and the jury returned a verdict "that the three deceased persons met their death by accidents at a fire which occurred in Mr. Wrench's premises, but how the said fire took place there was no evidence to prove; and the jury considered that the Royal Society's escape-men, the fire brigade, and the police rendered all the aid in their power to save the lives of the deceased persons."

Habits of intoxication are reported as having occasioned three fatal fires, the total number of these accidents unreported is, however, fearfully large. The number of deaths by fire from the ignition of wearing apparel during the past year has been truly awful; females and children in all ranks of life have been the victims, and the papers have been filled with suggestions for the prevention of such accidents. In one of the daily papers, people were recently advised after washing muslins, bed and window curtains, or children's clothes, to rinse them in water in which SALTPETRE had been dissolved. The *Medical Times*, in alluding to the melancholy deaths of the ladies, Laura and Charlotte Bridgman, says:—"The light fabrics manufactured for lady's dresses must be made blaze-proof. Nothing can be more simple. The most delicate white cambric handkerchief, or fleecy gauze, or the finest lace, may, by simple soaking in a weak solution of chloride of zinc, be so protected from blaze that if held in the flame of a candle they may be reduced to tinder without blazing. Dresses so prepared might be burnt by accident without the other garments worn by a lady being injured. When poor Clara Webster was burnt, we inculcated the same moral; and now the dresses of stage dancers are prepared in the way we recommended. Why are dancing ladies of rank to be exposed to danger from which their dancing sisters by profession are protected?"

Chloride of zinc is well adapted for this purpose, but *alum* answers almost as well, greatly improves the appearance, especially of coloured fabrics, and is oftener at hand.

The use of *fire-guards*, as a protection for children, has gone very much out of fashion; why should this be? The propensity of children to play with fire, candles, or lucifer matches is reported to have caused 24 fires during the past year, but this is not a tenth part of the accidents arising from this fruitful source of mischief.

The *daily* distribution of last year's fires was as follows:—

Monday	189	Friday	136
Tuesday	166	Saturday	148
Wednesday	167	Sunday	155
Thursday	153		

The average number of fires per day is three, but the actual distribution has varied as follows:—

There were	13	days on which	no fire occurred;	
while on	59	"	1 fire occurred...	59 fires.
	83	"	2 "	166 "
	83	"	3 "	249 "
	55	"	4 "	220 "
	40	"	5 "	200 "
	17	"	6 "	102 "
	9	"	7 "	63 "
	2	"	8 "	16 "
	1	"	9 "	9 "
	3	"	10 "	30 "
Total ...	365	"		1114 "

Their *hourly* distribution has been as follows:—

	HOUR.											
	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th	11th	12th
A.M.	62	76	40	42	23	25	20	26	23	16	24	26
P.M.	27	27	28	39	44	52	68	91	110	82	75	68

The probable causes of fire, so far as could be ascertained, were as follows:—

Accidents, unforeseen and for the most part unavoidable	11
Apparel, ignited in the person	3
Areas, lights thrown down	13
Bleaching vats	1
Candles, various accidents with	137
" ignited bed curtains	71
" " window curtains	43
Carelessness, palpable instances of	13
Charcoal and coke, hot	2
Chicory and coffee roasting	2
Children playing with candles	3
" " " fire	9
" " " lucifers	12
Cinders put away unextinguished	17
Coppers improperly set	3
Fire sparks (4 fatal)	73
" from locomotive engines	4
Fireworks, making (1 fatal)	3
Flues, blocked up	17
" defective and overheated	35
" foul and ignited	37
" hot air	2

STEAM FIRE ENGINES.

GENTLEMEN,—It is said "comparisons are odious," and yet they are indispensable if we wish to ascertain the relative values of either natural or artificial productions. When we read or hear of a steam fire-engine, the mind almost involuntarily reverts to the first contrivance of that kind, Messrs. Braithwaite and Ericsson's, and seeks by com-

Digitized by Google

paring notes to ascertain the superiority, or otherwise, of the new candidate. Your last number introduces to our notice a new steam fire-engine, by Shand and Mason. The picture is a pretty one, and the references very explanatory; but the practical mechanic wants to know something about the proportion of the parts, the pressure of the steam, and the rate of working; but upon these important points no information is vouchsafed.* With reference to its performances, all that is said is, "that one of these engines is found to deliver as much water in a given time as *three* engines of like size worked by twenty-eight men each;" which statement is positively untrue. In a report of the public trial of this steam fire-engine in October last, which appeared in the *Times*, we are told, "in ten minutes from lighting the fire sufficient steam was obtained to throw a 1lbs. jet of water to a considerable elevation. This was changed for larger ones up to one inch in diameter, the height from the latter being equal to that from a brigade engine when worked at its greatest speed. Two jets, one being ⅞ths of an inch, and the other a 16th smaller, were used at one time, and projected water to the same height."

From this account of its performances we learn that the engine never equalled *two* brigade engines, much less *three;* two brigade engines would have thrown two ⅞th jets, the steam fire-engine delivered a 16th less. As no scale accompanies the engraving at page 124, it is difficult to ascertain correctly the dimensions of the parts; as the machine is said, however, to be the same size as a brigade engine, I take the scale to be half-an-inch to the foot, which gives the dimensions of the pumps eight inches in diameter by six inches stroke, and their contents in round numbers 301·6; while a brigade engine with 7-inch pumps and 8-inches stroke is 307·9. In order, therefore, to get twice the quantity of water delivered in a given time, the steam engine must work at considerably more than double the speed of the brigade engine. On referring to your 18th volume, page 2, I see that in Messrs. Braithwaite's steam fire-engine the steam cylinder was 12 inches diameter, working two 10½ inch double-acting pumps, with a 14-inch stroke, and that it threw one jet of 1¼ inch; or two jets of ⅞ths inch; or four jets of ⅝ths; exactly the work of *two* brigade engines. In this engine the steam engine and pumps lay in a horizontal plane with direct action, requiring no fly-wheel or cranks—a very simple and beautiful arrangement, which Messrs. Shand and Mason have copied with advantage in their steam floating fire-engine. In their land fire-engine, however, they have adopted the most complicated and objectionable arrangement that could well be devised; as manufacturers, of course they undertake to make anything to order, and it is due to them to state that the present engine is no invention of their own, but the pet project of another patentee, by which they are not likely to add to their celebrity. A single glance at the engine will convince everybody at all conversant with the subject, that a little working followed by a little rest will render the working of the engine very difficult; and a gentleman who has just come over from St. Petersburg states that in the first attempt to set it to work on its arrival there, it broke down and proved a failure. To work such an engine with the foul and gritty water almost always used at fires, is certain destruction; and even Messrs. Braithwaite's steam fire-engine was open to this objection for street use. While working from a river (as in the case of a floating engine) this difficulty is not encountered. But even there the want of lubrication to the pump pistons entails great friction and needless wear and tear of the machinery. The open tapped pumps and oil-covered pistons of the ordinary fire-engine, lubricating the barrel at every stroke, is an admirable arrangement, with this immense advantage, that any sand or grit drawn into the engine is expelled by the succeeding stroke, and a few minutes' working with clean water thoroughly cleanses all the passages.

February 17th, 1859. VULCAN.

* We endeavoured in vain to get detailed information.—EDS. MECHANICS' MAGAZINE.

FACTORY SMOKE.

GENTLEMEN,—By simply altering our furnaces we may dispense with gigantic chimneys, and not only improve the health of our towns, but, at the same time, convert the *smoke*, by the following process, into "mineral tar, pitch, and varnish." All that is required being to erect the furnaces *below ground* instead of above, by which greater stability will be acquired. The plan may prove acceptable to a "Voice from the Potteries."

Let the furnaces be erected in 20, 30, or 50 stoves or more; the smoke is then conducted, by proper horizontal tunnels, into one capacious and close *funnel*, of some yards or more in length; this funnel is built of brick, supported by brick arches, and covered on the top by a shallow pond of water; the *chill* of the water gradually condensing the smoke, it falls upon the floor of the funnel in the form of tar, and is conveyed by proper pipes into a receiver, from whence it is pumped into a large boiler, and boiled to a proper consistence, or otherwise inspissated into pitch; when this latter is the case, the volatile particles which arise during the inspissation are again converted into an oil used for varnish. By this process the smoke is decomposed and destroyed, and the atmosphere is freed from the empyreumatic oils, acetic acid, soote, and numerous noxious salts (sometimes ammoniaco-chloride) given off by the soot and smoke.

J. BRUCE NEIL.

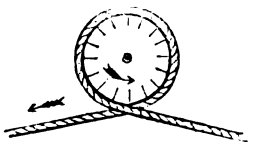
ON TELEGRAPHIC CABLES.

BY CAPT. JASPER H. SELWYN, R.N.

No. II.

I PROPOSE now to give the account I promised in my former paper of the mode to be adopted in underrunning the cable there spoken of, and to treat of some other points which it seems necessary to consider.

We take the cable as it at present lies, and either at one or at both ends commence the operation thus: The end is passed twice or three times round the barrel of the cylinder, thus:—



The arrows show the direction of the progress and rotation of the cylinder.

The cylinder being taken in tow, the result will be that the force of the paddle-floats on the water will be brought into action to raise the sea part, and deposit it again after the two or three turns have passed over the cylinder. During their passage (as the whole cable will thus successively be brought into view), opportunities will be given for examination, and should a fault be discovered, the cable is "racked" to its own part thus:—

and the damaged portion cut out, and replaced by one of several short pieces which must be kept at hand. To avoid the entire loss of the cable in case of breakage, and to indicate when a fault is coming up (if it be in the form of a "kink"), an auxiliary rope must be fitted with a weight to keep it at the required depth, and a nipper like that used with Burt's patent buoy, which will admit of the cable coming up freely, but will grasp it instantly, if broken and beginning to descend. And this will not probably be required to go to any great depth, for I need scarcely point out that before the cable would break at a fault, the weak part would most likely have been raised considerably off the bottom, so as to bring the weight and strain of a large portion of the cable on it. If the breakage should occur in any moderate depth, the cable might be dredged for and recovered by that means, if this should fail. The indication of a "kink" coming up would be derived from the slackening of the auxiliary rope.

In case of a gale of wind coming on during the operation, a length of cable must be provided, which will hang loose under the cylinder, from its frame, and when it is necessary from any cause to abandon the operation, the "rackings," as before, are put on at the points where the cable enters on and leaves the cylinder, and the ends of this loose part being connected with the cable by cutting and splicing, the "rackings" are cut, and it is allowed to fall free. It is evident that whatever the depth, the weight of the cable will be equally balanced on the cylinder, *i. e.*, the descending part will exert the same force to turn it in one direction, as the ascending part has to cause it to revolve in the other; and as the total weight on the cylinder as regards the cable can never be more than twice that due to the greatest depth (4 miles or tons of cable), a very moderate size of cylinder would suffice were it intended to accomplish the object of underrunning alone.

The cylinder is of course hung, so to speak, in a frame of wood or iron, which offers facilities for a platform for men, towing rings, &c., &c., but these are engineering details on which I need not now enter with regard to raising entirely. I have already said that this can be done by towing in the reverse direction, or (which is the same thing), passing the cable on in the opposite way.

I would here point out that no plan of raising by means of a steam engine on board a ship can be other than hazardous when the ship is pitching, for the engine continues its pull, irrespective of the enormous additional strain caused by the sudden upward motion of the stern; and there is another objection, for if only 40 or 50 miles per diem can be coiled into a ship's hold, under the most favourable circumstances, how long would the coiling of 2,000 miles take at sea? admitting that no gale of wind came to put a fatal termination to the operation. These objections are both obviated by the use of the cylinders. In the first case the lifting power is derived from the water itself, and is, as I before said, not absolute but comparative and yielding; and as regards the second, the speed with which the operation can be performed is only limited by that of the towing vessel.

As to the financial part of the question, I should add to what was stated in my former paper that while I have reason to believe, taking the weight of cylinder at 245 tons, that the sum of £12,000 is considerably in excess of the probable cost, I have been told, on good authority, that to build a vessel fit to carry 2,000 tons of cable for the Channel Islands line cost not less than £24,000. So that, for half the money, that work might have been done, and in greater security—for a cask will weather a gale which would sink a line-of-battle ship.

A small but sufficient model is now to be exhibited at the Polytechnic Institution, Regent-street, by Mr. King, who is already known there as a lecturer on subjects connected with ocean telegraphs. It has been shown to many nautical men—mercantile as well as naval—and to not a few engineers; and, while among the former I have scarcely heard a doubt as to its success, among the latter, the only objections have been to the towing and management at sea—an opinion on which, I may be excused for thinking, can best be given by the profession to which I have the honour to belong.

With regard to the cables themselves, I may, perhaps, be allowed a few remarks, though their construction does not so properly fall within a seaman's province. First, it seems to me that no great fault can be found with the form or weight of the present cable, when properly treated; and secondly, if we run into the extreme of a very light cable, the surface-currents may probably be found to act injuriously on a very slowly sinking body, while the admixture of hemp with which it has been sought to reduce the weight, is so far to be deprecated, as it introduces a vegetable substance, whose limit of duration under water (whatever it may be) is certainly sooner reached than that of the metals with which it is combined.

It will, perhaps, be contended that this matters little when once the cable is laid; but how will it act in case it should be necessary to relift it for repair, as has hitherto been the case with various lines, not unfrequently?

There is another fact which has been discovered by the careful experiments of a gentleman well known as a telegraphic cable maker. It is that in parts of a cable which has been passed over the brake wheels generally used for paying out, the copper wire which should have been, and was when made, in the centre of the gutta percha, has been often found nearly approaching the surface, thus:— and this without any external fault being discoverable. This is another evil effect of the soft core and rigid exterior which I have before condemned; and in saying that the present cable is not in fault, I merely mean that the great error is in the laying, not in the cables.

I will conclude by saying that neither public guarantees nor private credit can be expected to be given to the Atlantic Company so long as they do not propose some better means of laying than that which has already thrice resulted in failure. I enclose a sketch of the cylinder in tow;* and, with many thanks for the kindness which has afforded me space for these papers,

J. H. SELWYN.

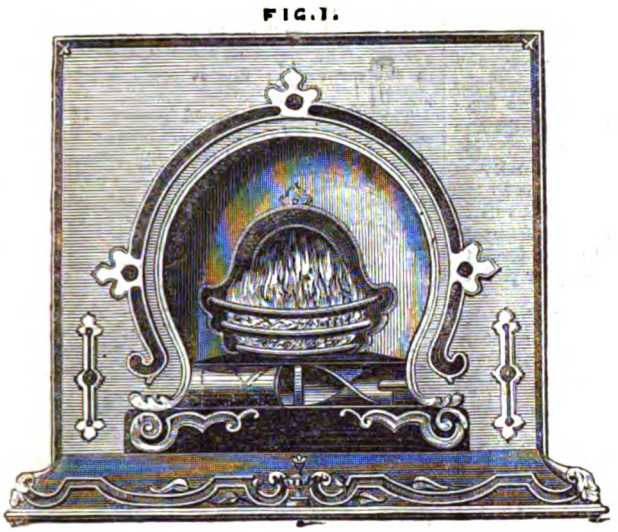
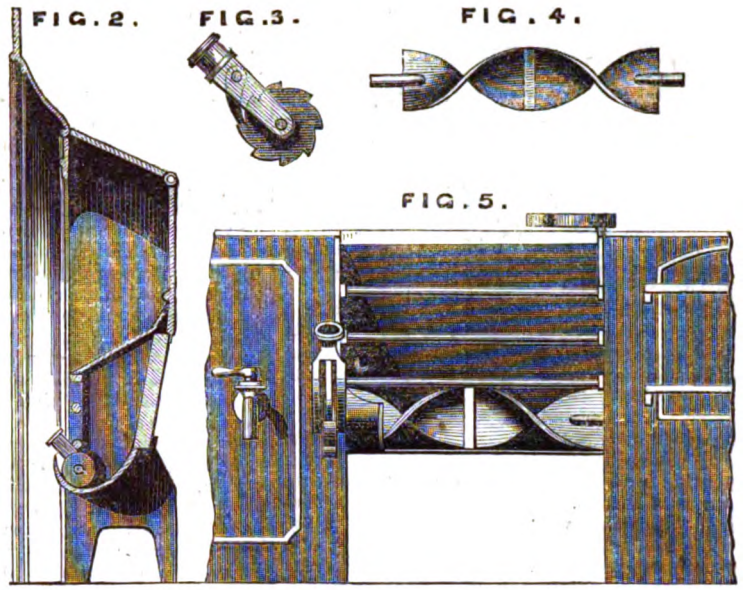
YOUNG'S SMOKELESS DOMESTIC GRATES.





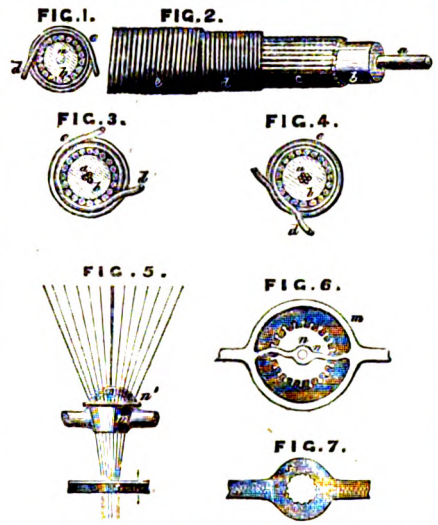
YOUNG'S SMOKELESS DOMESTIC GRATES.

MESSRS. YOUNG & Co., of Queen-street, London, have introduced a simple improvement in the form of domestic grates, which gets rid in a very simple and effectual manner of the nuisance of smoke proceeding from such grates. It consists of a simple and ingenious method of feeding domestic fires with fuel from below, which completely answers the desired end, and is no less applicable to the drawing-room stove than to the kitchen range. The whole invention lies in fitting below and in front of the grate a double-screw partly covered by a case, as shown in the parlour stove, fig. 1, in which part of the case is removed to expose the screw; Fig. 2 is a transverse section of another stove fitted with a similar screw; fig. 3 is a detached view of a ratchet wheel which is fitted on the end of the screw, with a pawl socket to receive a rod, poker, or other instrument by which the ratchet and screw may be turned; fig. 4 is a detached view of the double screw; and fig. 5 is a view of a portion of a kitchen range fitted with the arrangement, the principal part of the case being here also removed. It will be readily understood that when coal is placed in the case at either end, and the screw is turned by means of the ratchet wheel, the coal will be carried by the screw from each side towards the middle of the fire, and forced in beneath the hot fuel in the grate, through which the whole of the gases generated from the fresh supply must necessarily pass. We have seen the plan in operation, and believe it is exceedingly well fitted to get rid of all further trouble with the smoke of household fires.

DE BERGUE'S SUBMARINE TELEGRAPH CABLES.

MR. CHARLES DE BERGUE, of Strangeways Ironworks, Manchester, has just completed a patent for improvements in submarine telegraph cables, and in machinery for manufacturing and paying-out such cables. The first part of his invention consists in making a cable so that its specific gravity shall only slightly exceed that of water, and so that it shall have no tendency to form snarls or kinks. To effect this he takes the gutta percha core enclosing the copper wires, and envelopes it with small cords, placed in parallel to the gutta percha core, and paid round with two layers of twine in opposite directions. The straight cords are to give the cable strength lengthways, and may be made of metallic wire, or of fibrous materials. A few fine metal wires may be inserted in combination with the small cords.

Figs. 1 to 4 of the accompanying engravings illustrate this part of the invention. Fig. 1 is a transverse section, and Fig. 2 a side elevation of a short length of cable, the parts of which are exposed to view, by removal of other parts. *a* is the copper-wire conductor, and *b* the gutta percha covering; *c*, *c* are the longitudinal strengthening



cords; *d* is an inner layer of twine bound round the longitudinal cords in one direction; and *e* is a second layer bound round in the opposite direction. Figs. 3 and 4 are transverse sections, similar to Fig. 1, but representing the core as enclosing three and seven telegraphic wires respectively, instead of one only.

The second part of the invention consists in making suitable machinery for covering the gutta percha core with the straight cords or wires, and for paying over the cable with the double layer of twine at the same time.

Fig. 5 is a diagram illustrating the method of laying the longitudinal cords upon the core. It consists simply in providing suitable guiding tubes or apparatus for directing the cords evenly upon and around the core as both are received from the reels from which they are separately delivered whilst the cable is being formed. Two guides are shown in the sketch, one, *m*, being in plan, and drawn larger in Fig. 6, from which it will be seen that a separate channel is provided for each of the longitudinal cords, and also a central guide, *n*, for the core, the latter being supported by a bridge piece *n'* across the piece *m*. The cords and core, after passing through the guides *m*, *n*, also pass through the second guide *s*, which presents an orifice corresponding in size with the actual external dimensions of the cable previously to binding, and presenting a series of notches or grooves corresponding with the number and size of the cords employed. Fig. 7 is a plan of the guide *s*, to a scale corresponding with Fig. 6.

A vertical arrangement of the machine is preferred, as in Fig. 5, which does not, however, show the reels (from which the cords and core are delivered). The binding with twine is effected by machinery similar to that ordinarily employed for similar purposes, except that two revolving shuttles or binders are employed instead of one, and that they revolve in opposite directions at the same time.

The last part of the invention consists in arranging suitable paying-out machinery for this kind of cable. From the nature of the cable, while being paid out, there will be comparatively no strain upon it as due to its own gravity, because it will weigh so very little under water; but it should be payed out very slack, that it may accommodate itself to currents, or to irregularities in the bottom of the ocean; to effect this, it will be simply necessary to have a paying-out machine of the most simple description—just a few grooved pulleys, over which the cable will pass, and which will have to be driven by a steam engine, but so arranged that its speed can at all times be regulated in proportion to the speed of the vessel through the water.

ARKELL AND MELHADO'S APPARATUS FOR SUBMERGING TELEGRAPH CABLES.

MR. P. ARKELL, of North Woolwich, and Mr. A. Melhado, of Bayswater, have patented an apparatus for preventing cables being injured by torsion during the paying-out. In order to neutralise this effect, they propose to attach to the cable at given distances apart, and while it is being submerged, floats of such a construction that, when they enter the water, they will offer considerable resistance to the tensile strain of the cable, and at the same time serve to buoy it up, and relieve the paying-out machinery from a portion of the direct strain of the cable.

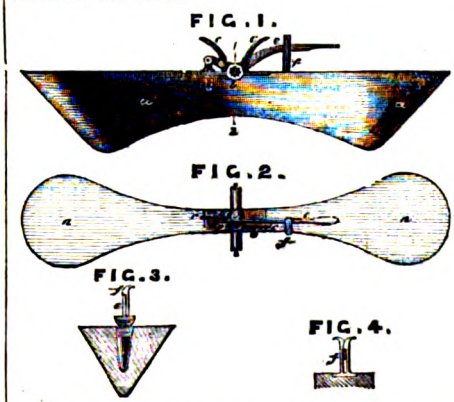


Fig. 1 shows, in side-elevation, their novel construction of float; Fig. 2 is a plan, and Fig. 3 a cross-section on the line 1, 2, of Fig. 1. It consists mainly of a wedge-shaped

Digitized by Google

block of wood, *a*, *a*, rounded and tapered off at its ends, and hollowed out at its sides, which form will enable it to ride easily in the water, and offer a sufficient resistance to any force that may be imparted to it, having the tendency to cause one end of the float to dip, and the other to rise. Upon the upper face of the float is a metal clip for gripping the cable. *b*, *b* is a plate formed with a semispherical recess for the reception of the cable. This plate is screwed down to the block *a*, *a*, and it is provided with horns or guide-pieces, *c*, *c* (detached at Fig. 4), and a bracket *d*. Hinged to this bracket is a hand-lever *e*, furnished with a semicircular recess corresponding to that of the plate *b*. The inner faces of these recesses are grooved or ribbed, to ensure a firm grip of the cable that is to be held between them. A spring catch *f* is driven into the block *a* in such a position that when the hand-lever *e* is pressed down, so as to grip the cable (it being guided in its course by the horns *c*), this spring catch will hold the lever fast, and the teeth or ribs of the gripping surface pressing into the gutta-percha or other soft covering of the cable, will take a firm hold of the cable.

In applying their invention, they provide a number of these floats, using more floats per mile in deep seas than in shallow waters. Two men take up a float and hold it (with the lever hand thrown back) immediately under the passing cable. When the signal is given that a certain length of cable has been run out, one of the workmen will strike down the lever handle, and by thus putting a grip upon the cable, will firmly secure the float thereto. At the same time, the float being let go, it will enter the water with the cable, and be submerged with it, but being of a buoyant character, it will serve for a time to keep the cable suspended in the water, and thus relieve the paying-out apparatus (as before observed) of considerable strain. When a series of floats have been thus submerged with the cable, their tendency will be to assume a horizontal position in the water, and being firmly secured to the cable, they will effectually resist and neutralise the tendency of the unrolled coil of cable to turn in the water and twist the fibres of the wire of which it is composed.

THE ENGINEERS OF THE ROYAL NAVY.

GENTLEMEN,—In perusing your valuable periodical of the 25th inst., under the heading "The Civil Service" occurs the following passage:—"It is our purpose to maintain—at all hazards, and without reserve—the indefeasible rights of the practical, useful, and efficient men of the Civil Service, and also of the Naval and Military Services." Emboldened by these remarks, and knowing also that your valuable Journal is keenly scanned by those high in authority, I would wish to call attention to the *liberal* style of remuneration awarded to the staff who play so prominent a part in the well-being of our steam navy. By reference, then, to the "Navy Estimates" we find that the "Chief Engineer and Inspector of Steam Machinery of Her Majesty's navy"—him upon whose judgment and integrity depends much of the efficiency and well-being of our millions expended in steam machinery, and who is *de facto* comptroller of the steam machinery of the British Navy—receives £150 per annum less than that accorded to a chief clerk! Imagine now that some of this costly machinery, in many cases verging in value on £50,000, is received and fitted to some one of our splended frigates. Its future efficiency and preservation is entrusted to an officer—a naval engineer—holding a commission, but remunerated with a scale of pay not even on a footing with an Admiralty messenger. This officer again is aided in his duties when the ship is called for active service by a First Class Assistant Engineer, receiving a pay some few pounds less than that of a hall porter. And the staff is completed by other Assistant Engineers, with rates of pay but slightly in excess of those lucky domestics who keep their "weary watch" in the tempestuous neighbourhood of Whitehall. How widely different are those things managed in the service of foreign powers, to say nothing of that management long since found imperative to the due efficiency and economy of our large steam companies. I trust that you will direct some of your attention to this point, in that which seems to you a labour of love, viz., the improvement and increased efficiency of our "Royal Steam Navy," and am your's, &c., NAVALIS.

ON A QUICK-WORKING POWER ENGINE.

(*Continued from p.* 121)

THE WORKING AND MANAGEMENT.

The preparation for working would be by fixing the end of the beam at about the highest and lowest levels, filling with water the two cylinders under the pistons and the pipes and reservoir, making a vacuum in the small chamber, and screwing two of the springs forward against the parallel rods, and advancing the other two less; the sliding valves at the division of the pipe and at the junction of the two pipes being shut. No air vessel would be wanted to secure continuity of motion in the water; which would be done by the springs continuing the action of the pistons without an interval in their changes. A pressure of air, however, would be desirable to give force to the descent of the contents of the upper part of the pipe through the vacuum.

But there is the difficulty that, if the valve at the junction of the pipes were opened together with the one at the division of the single pipe, the air would pass back to the reservoir, and through it and the perpendicular tapering pipe, as in a syphon, up to the vacuum, and against the discharge from above. Therefore the valve at the junction should be opened a small fraction of a second after the other, by mechanism acting on both with one motion. The withdrawing of the valve at the junction, when the water should have fallen through the space in the vacuum, would set the piston free; and the pressure from the discharge through the tapering pipe on the full and close reservoir, would give a sudden and very strong impulse to the movement.

When the engine was filled with water the two sliding valves would have been closed; and on their being opened the hollow left at the summit of the pipe would be filled up from the air vessel. To prevent the vacant chamber being refilled out of the current passing through it, all the water should be exhausted of its air. Then if it were distilled there could be no generation of animal or vegetable line, or deposition of earthy matter; and it might be prevented from absorbing any air from the vessel, by a film of oil on the liquid contents.

At the point of time when the sliding valve at the division of the pipe was being withdrawn, the self-acting coupled valves in the bottoms of the cylinders would be held a little open, and the side valves would be dropped by their own weight and that of the water over them in the pipes. The nearly instantaneous withdrawing of the valve at the junction of the pipes would set the pistons free to yield to the first pressure of the discharge on the reservoir; gravity in the water would assist the lower more than it resisted the depression of the higher one. The springs would play in opposite directions to promote the action, and the intensity of the injection would be multiplied in amount against the forced piston, without being countervailed by re-action according to the law of the paradox against the forcing one. The reservoir and the cylinder open to it at bottom would be together like a vessel close as well as full, owing to the influx shutting up the side valve at the entrance into the pipe; while the corresponding side valve in the cylinder at bottom would be dropped, and give passage to the discharge from the pump through a pipe divided and opening at one place, and open to an air vessel. The self-acting side valves, and those in the bottoms being respectively closed and opened with the changes of the strokes, the interior of the engine would be always divided into two parts both full, but only one quite close, as is required for the operation of the law of the paradox. Thus the principle of the plan would be made good. The forcing piston, indeed, would be resisted solely by general friction in the liquid and the solids, since gravity in their ascent would be balanced by the same in their descent. The difference, then, between the internal resistance and the internal force would afford a power very far beyond what was borrowed for self-working, and disposable for any duty.

The working could be regulated by a stopper with a press screwed against it, and by the sliding valves being inserted more or less, or not at all, to impede the current, or leave it quite free. The action would be stopped by thrusting in these valves; the mechanism by which this was done being so adjusted as to shut them exactly together. The re-action would spend itself partly in the air vessel; and it could not move the pistons.

Then the stoppage should be so timed as for a crank worked by the beam of the double pump to be in a position as to give, in the removal of the action, the desired direction forward or backwards to the wheel attached to the other body attached to the engine. A crank, supposed to be a bore, would be either up or down at the end of the beginning of a stroke. Then, if it were up, and the working were to be forward, it ought to be a little forward out of the perpendicular, that the rod from the beam might pull it down forwards. Or if it were down, it ought to be a little back for the rod to push it up from behind. It could be in these positions in working forwards only after a stroke was begun. The time might be hit exactly enough, if the action were first checked by unloading the empty stopper, and inserting the two slides slowly. To reverse the action the stoppage should be before the stroke was quite completed. The crank, then, if up would be a little backward, and if down a little forward from the perpendicular, and in the former case the rod would pull it down backwards, and in the latter lift it in that direction.

The outward working might be by one end of the beam, or by both ends; and the two ends might do different kinds of work or the same kind. One engine might serve for two paddle-wheels, if that were preferred to having two engines. It might be competent to such duty with the larger wheels, as being able greatly to surpass steam engines in the intensity of force, because the parts liable to bursting might be of any massiveness, whereas a boiler must be rather thin not to impede the penetration of heat too long, while for amount of price distinguished from degree, it might be of the largest dimensions that could be desired. Magnitude is objectionable in the common hydraulic press, because it retards the operation, unless equally greater power is used to inject in a larger volume; but this engine would work itself, and slowness would be out of the question. The only apparent difficulty is, that if great cylinders had one bottom valve and a side one, these might be too large to play nimbly enough. But there might be as many openings in the bottoms and at the sides, and as many pipes as was convenient, with arrangements to enable the sliding valves to all shut exactly together, and to be opened, some a moment later than the others.

AN UNREWARDED INVENTOR.

SOME while since a Mr. Phillips took out a patent for an ingenious arrangement to give to a swimmer additional powers of buoyancy and rapidity of motion. The apparatus, or rather that portion of it intended to fit around the ancles, *expanded and collapsed* somewhat after the fashion of an umbrella, as the wearer struck out or drew in his legs. We had altogether lost sight of this invention when accident informed us of the patentee's decease, together with some facts which may not be altogether uninteresting to our readers. This patent is now in the hands of Miss Phillips, of 44 Clipston Street, a maiden lady of great age, and the sister of the inventor. Miss Phillips, upon the subject of the patent, writes to a correspondent who is interesting himself in its sale: "I have now outlived all my relatives and old friends; I am now the only living person that can even relate an authentic anecdote of Mr. Hogarth the great painter, having been the companion of my cousin Mrs. Lewis, who supported Mr. Hogarth in his last moments. All my early days, to my 22nd year, were passed in Mr. Hogarth's house at Chiswick, up to his death and burial in the vault. After that, his effects and myself came to my

Digitized by Google

uncle, Mr. Hart, who had the honqur of serving His Majesty George the Fourth for 48 years as Chief Clerk in the Duke of Cornwall's Office, then in Somerset House, and Second Clerk in His Majesty's Kitchen, and died in the King's service in the year 1823. My brother was writing a biography of Mr. Hogarth's works, and anecdotes of our family, and I think he had nearly brought his notes up to the restoration of the tomb at Chiswick, having repaired that monument at his own cost in 1825, and again in 1832, but after that period it wanted re-leading and he had not the means of doing it, and my brother gave the tomb to Mr. Hogarth of Aberdeen, who restored it three years ago, and whose property it now is. My brother's last moments were intensely increased by the pain of leaving me wholly destitute. My only hope is in the sale of the patent."

We give the poor old lady's simple narrative as it is written, and trust her forlorn condition will reach the eye of some of the many who are ever ready to help the deserving.

INDIAN ITEMS.

Mr. Purser, chief engineer of the Allahabad and Cawnpore section of the East Indian Railway, has resigned his appointment, and Mr. Campbell, formerly an assistant on the Caledonian Railway, has succeeded Mr. Gower as locomotive superintendent.——Mr. R. B. Thomas, agent for the Punjaub Railway Company, arrived by the last mail. Mr. Thomas is to be stationed at Kurrachee as transit agent for the despatch, on arrival, of all stores and material intended for the railway. His office will be no sinecure, as from 25,000 to 30,000 tons of stores are on their way out.——An electric time ball is now dropped daily at the Colaba observatory, to enable the shipping in the harbour to adjust their chronometers.——Mr. H. P. Owen has been appointed deputy-superintendent in the Electric Telegraph Department, at Bombay; Mr. J. T. Blisset, deputy-superintendent at Madras; and Mr. W. W. Mayes, deputy-superintendent of the east coast line.——The half-yearly report of the Madras Railway Company states several facts of interest. On the south-west line between Goriattum and Beypoor, the progress of the works is, with one exception, satisfactory, and the line will be finished as fast as the permanent way materials can be transported to it. The further opening for traffic to Vaniembady is, however, likely to be delayed in consequence of difficulties experienced with a bridge over the Palar river. On the completion of this bridge the line will be opened to Salem, upwards of 200 miles from Madras. On the western half of the line satisfactory progress is stated to have been made, and this division is expected to be completed from Beypoor to Paulghaut, 70 or 80 miles, by the end of the year. The local government has been instructed by the home authorities to proceed with projected improvements of the port of Beypoor, and of the water communication between the railway and the town and harbour of Cochin. This is to be effected by a short canal from a point where the railway touches the Ponany river, and the navigation which extends by Cochin southward and parallel with the coast nearly to Cape Comorin. The Bangalore line which leaves the main south-west division near Vaniembady, is being surveyed; it will be about 80 miles in length. Surveys are also to be made for a branch to the Neilgherry hills. The survey of the north-west line has been extended to its proposed junction with the railway from Bombay in the Raichor Dooab, formed by the rivers Krishna and Tungboodra. The length of this line from Areonum, where it leaves the trunk line at 42 miles from Madras, will be about 330 miles. Between Areonum and Cuddapa, the works are being vigorously pushed on. The company has now 96 miles in working between Madras and Goriattum, and the receipts for the six months ending December 31, 1858, were £21,720.——It is stated that a Dutch company intend running steamers between Java and Borneo, Singapore and China.——A corps of civil engineers is to be formed for permanent service in India.——The estimated cost of the first section of the Great Southern of India Railway, from Negapatam to Trinchinopoly, has been fixed at £500,000.——The Oriental Inland Steam Company have concluded contracts for two new steamers and two new trains of barges, consisting in all of 12 vessels of large size. These will, at an early period, be added to the other vessels of the company already in India. The engines will be high pressure, intended to work to 800-horse power.——Mr. Russell, the *Times* correspondent, says, it will be good policy to have vessels of lighter draught, armed with howitzers and a few Enfields, on our large Indian rivers for some time to come.

The Armstrong Gun.—We find that in the Armstrong Gun, as now made, the large screw at the breech is formed hollow, and the charge is passed into the gun through it. With this arrangement the moveable breech-piece is only required to close the breech, and receive the force of the explosion. Both the slot and the breech-piece are therefore smaller than they would require to be were the gun loaded through the slot.

NOTICES.

The Speech of Sir John Pakington on the Navy Estimates, and the Report of Mr. Baddeley on London Fires, which we have published annually for many years past, occupy so much of our space this week that we are compelled to defer our paper on "Naval Architecture" until next week.

The Mechanics' Magazine will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

The demand for Mr. E. J. Reed's paper—

"On the Modifications which the Ships of the Royal Navy have Undergone during the Present Century, in respect of Dimensions, Form, Means of Propulsion, and Power of Attack and Defence,"

has been so great that the Journal of the Society of Arts, the Mechanics' Magazine, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

A friendly correspondent sends us the following suggestions:—

Gentlemen,—As a subscriber to your admirable Magazine, permit me to congratulate you upon and thank you for the improved state in which it now appears. Not the least instructive part of it is that contained in the notes from the different parts of England concerning the iron, &c., trades. Without wishing to appear a meddler, I think that they might be greatly improved by printing the subject of each paragraph in larger type than the context, something after the arrangement you have adopted with reference to the list of patents, this is the only appearance of improvement I or perhaps any body else could suggest, though your more experienced judgment may not think it necessary to adopt it.

Spontaneous Generation.—There is one question occurs to me with reference to this interesting subject of which no one, I think, has offered a solution. If there be no such thing as spontaneous *generation* (not creation; the neglect of this distinction has, in my opinion, been the cause of much vituperation that might well have been spared), whence comes the moss or vegetable well known to opticians as growing upon the object glasses of telescopes. No one will, I think, be so bold as to say that glass always did exist, yet, as soon as it was invented a parasite seized hold of it, one that is unknown anywhere else. Take ink, again, every one knows the mould that grows on ink, this mould is quite distinct from any other species of its class, and is found only on ink: many other instances might be brought forward. The doctrine of spontaneous generation is assuredly the ground of much misconception; no sooner are the words spoken, than certain men conceive an idea of *self-creation* of matter, and brand the supporters of the theory of spontaneous generation with the absurd epithet of atheist, whereas, by this latter phrase, nothing more is meant than that the laws of nature are in operation to work out the will of Providence impressed on matter at its creation. Let any one of these ultra-theists (they leave Christianity with its brotherly love far behind them) place a drop of the solution of any salt crystallizing at ordinary temperature in the focus of a microscope, and watch the generation of the crystals and their growth; if, after in this manner assisting at the birth of a new thing, he does not thenceforth hide his diminished head, and what is more to the purpose, rule his tongue, he is not a mortal fallible man and a brother of gentlemen.

Yours, &c., P. H. H.

Law Case.

VICE CHANCELLOR'S COURT.—March 2.

(Before Vice-Chancellor Sir W. P. Wood.)

GRIFFITHS *v.* TURNER.

This was a motion for an injunction to restrain the defendant from infringing the plaintiff's right in respect of a whisk and churn, which had been exhibited at various agricultural meetings in the course of last year, and of which Mr. Kent, the patentee of the rotary knife cleaning machines, was the sole licensee. It was urged that this was a case in which the question would be better tried by a jury summoned before this Court than in the ordinary way at law.

Mr. Rolt and Mr. Fooks supported the motion; and Mr. Amphlett and Mr. E. E. Kay were for the defendant.

The Vice-Chancellor said that the delay which had taken place was such as to disentitle the plaintiff to the interlocutory injunction. It did not appear that this was a case contemplated by the Act of last session, which provided for the summoning a jury before this Court when in any suit a question of fact was raised. Now, the action in this patent case was not an action to try a question of fact raised in a suit, but an action to determine the legal right, and to such an action the suit was merely auxiliary. The trial would therefore take place at law, under the ordinary order, directing the motion to stand over, plaintiff undertaking to try an action at law.

CURRENT EVENTS

IN THE CENTRES OF THE IRON, COAL, MACHINE, AND SHIPPING TRADES.

[compiled by our own correspondent.]

Shocking Railway Accident at Leamington: Commencement of the Inquest—Sir William Armstrong and his Workpeople: Address to Him—Sunderland Dock and River Wear Amalgamation—Aston Hall and Birmingham—Royal Agricultural Show at Warwick—Increase of Machinery at Blackburn—Oriental Inland Steam Company: Increase of Vessels—Movement of Colliers for a Short Hours' Bill: The Petition—Opposition to the Boot-Sewing Machine at Stafford and Northampton.

A disastrous railway accident occurred on Saturday on the Rugby branch of the London and North-Western Railway near to Leamington, by which two drivers and a stoker were killed and three passengers slightly injured. The train which leaves Rugby for Birmingham at 10.5. in the morning, had reached an embankment near Radford, a short distance from Leamington, when the driver and fireman became aware of something amiss with the leading spring link of the engine; they put on the brake, and did all they could do to stop the train, but were unable to effect their purpose. Very soon the engine left the rails, and rolled down the embankment. At the inquest on Monday William Clayton, a servant of the company, who was also on the engine at the time of the accident, deposed:—"We were going at the ordinary speed, say thirty-five miles an hour. 150 yards before the engine was off the line the adjusting link of the left-hand spring broke, which would cause the engine to ride on the axle-box; and before she went off she jumped badly. We saw the spring broken; it hung over the framing, the break was put on, and she left the rails after going about 150 yards." Mr. M'Connell, the engineer of the line, said that the engine was one of Sharp's and in good repair. The reason of the engine going off the line seemed to be beyond the comprehension of the witnesses, who had known spring links to break, but not for an engine to leave the rail in consequence; it would be more likely to keep it on the line. The part of the road where the accident took place is level; there is a curve, the radius of which is three-quarters of a mile, on the spot. The inquest was adjourned till to-day (Friday) for further scientific evidence.——A most gratifying reception was given to Sir William Armstrong, when, on Monday afternoon, for the first time since he received his knighthood, he visited the Elswick works at Newcastle. His men all assembled and congratulated him in an enthusiastic but respectful manner. Sir William arrived in his carriage, accompanied by Lady Armstrong, and on entering the gates to the yard in which the workmen were assembled, was received with loud and enthusiastic cheering. In addition also to gentlemen of local distinction, there was a considerable muster of ladies present. The extensive works were gaily decorated with flags, &c. Cannon boomed from various parts, until from a temporary platform, an address from the managers and workmen was read and presented to their distinguished employer. Among other terms of felicitation, the men thus addressed Sir William:—"We who have occasionally been permitted to witness your indomitable perseverance in pursuing your experiments under most perplexing circumstances with the most extraordinary zeal and energy, and have observed how frequently your disappointments or failures have been made the key to the successful attainment of your purpose, have become involuntarily interested in your most triumphant success, and do most sincerely rejoice that to some extent the value of your invention and services are recognized by the government of our country." Sir William, in his reply, intimated that the skilled artizans of the locality would, he hoped, be benefitted by his success, and ordered an entertainment for the men, which is yet to come off.——At the half-yearly meeting of the Sunderland Dock Company, on Monday, Mr. G. Hudson, M.P., the Chairman of the Directors, explained the present position of the undertaking, and the terms upon which it was proposed to transfer it to the hands of the River Wear Commission. There was no dividend proposed to the original proprietors, the dividend on the preference shares requiring all the profits; but, though some discussion took place, the feeling was hopeful, the report was unanimously adopted.——A series of ward meetings are being held in Birmingham to promote a movement for raising by the 1st of June the sum of £10,000, in order to secure Aston Hall and park to the people of the town.——It is announced that the sum of £4,200 has already been collected in furtherance of the ensuing annual meeting at Warwick of the Royal Agricultural Society of England. It has been resolved to have no pavilion dinner on the occasion.——At Blackburn Messrs. Richard Thompson and Sons are erecting a new spinning mill, to contain 38,000 spindles, with preparations. The situation is close to the Leeds and Liverpool Canal. Throstle Nest Mill, which has been standing for nearly two years, the machinery being sold, was last week purchased by Messrs. Robert and John Railton, ironfounders, and will be got to work as speedily as possible. This was the only mill in the town standing through the late depression in trade.——The Oriental Inland Steam Company have concluded contracts for two new steamers and two new trains of barges, consisting in

Digitized by Google

all of twelve vessels of large size. These vessels will at an early period be added to the other vessels of the Company already in India, for navigating the great rivers of that country. The engines of the new vessels, which will be high-pressure engines, are intended to work to 800 horses' power.——Acting in unison with the Yorkshire colliers, the colliers of South Staffordshire are making vigorous preliminary efforts to secure numerous signatures to their nine hours' petition.—— All the Stafford operatives in the boot trade, who form part of unions, have struck work, in consequence of their masters issuing machine-bound tops. Nearly 500 men have left the town "on tramp" in one day. As many as have left remain; and as they are unconnected with the union, they are expected to help the masters to introduce the machinery.

NOTES FROM THE EASTERN DISTRICTS.

[FROM OUR OWN CORRESPONDENT.]

Chelmsford Water Supply—Testimonialising a Locomotive Superintendent—Screw Steamers for the Greenland Seal Fishery—Vernatt's Drain—Baths at Lincoln—Ancaster Stone — Singular Memorial Tower — A Challenge on Draining — The Dams in the Nene and the Wisbech Authorities—The New Telegraph through Newmarket.

In recent "Notes" allusion has been made to steps taken at Chelmsford with reference to the improvement of the water supply of that place. The committee of the Local Board of Health to whom the subject was referred have considered the report presented by Mr. Chancellor, their surveyor; and the result of their deliberations is, the expression of an opinion that the supply of the town is at present inadequate, and that it would be desirable, if possible, to procure an additional quantity of water from springs below the property of the Board in Hall-street. ——Mr. Kitson, locomotive superintendent of the Cambridge division of the Eastern Counties Railway, is about to leave England for Belgium. On Monday evening, Mr. Kitson was testimonialised by the men employed in his department.——Two screw steamers have left Hull for the Greenland seal fishery, viz., the *Labuan*, of 1,000 tons, and the *Corkscrew*, of 400 tons. A large concourse of persons—upwards of 10,000—witnessed the departure of the steamers. ——Vernatt's drain in the Spalding district is about to be widened and deepened from end to end.——Steps are being taken to promote public baths at Lincoln.——Mr. Denison, M.P., in announcing the completion of St. James's church at Doncaster, observes in a letter to the Great Northern board:—"It is probable that the pleasing effect of the Ancaster stone in this church, together with its great facility of working and its durability (testified by many of the old Lincolnshire churches), will bring it into use in districts from which it had been excluded until the opening of the Sleaford line lately brought the Ancaster quarries into connection with the Great Northern Railways."——The Rev. E. Bull, rector of Pentlow, is erecting as a memorial to his father and predecessor, the Rev. J. Bull, an octagonal tower in the Tudor style. The site is an elevated spot in the rectory grounds, and the material employed is red brick with white dressings. The diameter at the base is 16 feet, and the structure will taper to the height of 60 ft., where it will be contracted to a diameter of 10 feet. It will then rise perpendicularly 30 feet higher, making a total elevation of 90 feet. The tower will be lighted on the sides by lancet windows, and will be surmounted by a machicolated cornice and embattled parapet; and a spiral staircase will ascend in the interior to the summit, from which the visitor will doubtless be ready to exclaim—

"Straight my eye hath caught fresh pleasures
When the landskip round it measures."

——The Huntingdonshire farmers have thrown down the gauntlet and challenge the United Kingdom to enter into a competition for pipe-tile draining 4 feet deep.——The Nene Valley Commissioners have been foiled in their application to the Court of Chancery for an injunction to restrain the Wisbech town council from further interference with the dams in the river Nene, Vice-Chancellor Wood remarking that they had failed to show the necessity for the former, and observing that they did not give an undertaking for the completion of the original works. The commissioners, in consequence of this decision, have suspended the restoration of the dam at Gwyhirn.——The wires of the new telegraph system from the metropolis to the continent viâ the eastern coast are to be carried by the company (British and Irish Magnetic) in pipes under the main street at Newmarket for some considerable distance upon the London and Bury turnpikes. Some of the posts have been removed from the east entrance of the town as far as the exercising heath extends, in consequence, it is stated, "of the noise from the wires, &c., being objected to by owners and trainers of race-horses."

NOTES FROM THE SOUTH WEST.

[FROM OUR OWN CORRESPONDENT.]

Cambridge University Non-Gremial Examinations: Meetings at Bristol.—Welsh and North of England Steam Coals.—Postal Communication between Ireland and Bristol.—Plymouth Great Western Docks.—Salisbury and Yeovil Railway.—Portsmouth and the Admiralty.—New line of Steamers from Southampton to the United States.—The Water Supply of Southampton.—Schooner for the Natal Trade.—The West India Steamer "Thames."—The Packet Service Estimates.—Bristol and South Wales Union Railway.—Speed of the "Ellora."

There has been a very brilliant gathering at Bristol with reference to the non-gremial examinations of the University of Cambridge. A public meeting, presided over by Earl Ducie, was followed by a dinner, and the host of speeches delivered expressed cordial approval of the movement made by the university authorities to adapt their system to the requirements of the age.——An interesting item occurs in the half-yearly report of the Taff Vale Railway Company. It appears that the directors have been appealed to by the Aberdare Steam Coal Association for pecuniary assistance to enable them to conduct a series of experiments by competent and authorised Government officers, for ascertaining the comparative values of Welsh and North of England steam coals, and that a subscription of £250 has been made by the railway company. The results of the experiments are not yet officially announced, but it is stated that they confirm the report made to Parliament on the subject some time since by Sir Henry de la Beche and Dr. Lyon Playfair.—— Postal communication is about to be accelerated between Bristol and Ireland. —— At the half-yearly meeting of the Bristol and Exeter Railway Company, the chairman referring to the Great Western Docks at Plymouth, said that property had been for many years in a state of almost hopeless depression, but he was happy to say there was now a great change. The floating dock had been completed, and the shipping interest was likely to avail itself of the accommodation to a greater extent than was anticipated.——Mr. Brunel, C.E., in reporting to the proprietors of the Plymouth Great Western Docks says the works undertaken last year for the protection of the outer forestead of the old Millbay pier, and the temporary means adopted for securing the masonry of the sea-wall have hitherto proved effectual to preserve the works from injury during storms. Some more permanent remedy will, however, Mr. Brunel adds, be required to make the works completely secure. The pontoon or floating pier continues in a satisfactory condition. During the last half-year considerable progress has been made in the construction of works consisting of a sea wall-and pitched slope on both sides of the entrance gates, for protecting the sea-face of the inner or floating basin. The entrance gates continue to work well, and being now protected by storm gates have suffered no injury from heavy seas. At the graving dock a large pumping engine for emptying the dock has been put to work, and has been for some time in use; but the dock has been so much occupied during the winter that it has been difficult to determine with certainty what steps may be required to remove some impediments in the action of the pumps, which appear to interfere with the smoothness of the engine's working. At the entrance to the outer basin, between the dam heads, it will be desirable to proceed with the construction of the dolphin or extension of the east dam head. Increase of business has rendered necessary the erection of several new warehouses.——The portion of the Salisbury and Yeovil Railway between Salisbury and Gillingham is expected to be opened for traffic in the course of a month, and working arrangements are being negociated with the London and South Western. The completion of the line to Yeovil, so as to enable it to be opened simultaneously with the London and South-Western extension to Exeter, is to be pressed forward as fast as possible.——The Admiralty authorities have made an adverse report on the Portsmouth New Dock and Railway Bill.——Another line of first-class screw steamers is about to be established between Southampton and the United States, the American Government having given a mail contract to the vessels of the North German Lloyds, running between Bremen and New York and calling at Southampton either way for French and English mails and passengers.——The special works committee of the Southampton Town Council are making inquiries with the view of checking the waste of water continually occurring through the neglect of owners and tenants not having their water taps and fittings kept in good repair.——A brig of 175 tons, 104 feet in length, and 20 feet beam, has been launched by Mr. G. Lungley at Northam for the Natal trade.——Mr. West, late chief officer of the West India Mail Company's steamer *Thames*, has been appointed commander. The *Thames* is to be employed on one of the inter-colonial lines.——The total estimate for the Post Office packet service for 1859 is £991,596 against £988,488 in 1858.——Considerable progress is being made with the works of the Bristol and South Wales Union Railway.——The *Ellora*, a recent addition to the splendid fleet of the Peninsular and Oriental Steam Navigation Company, made her trial trip in Stoke's Bay on Saturday, previous to her departure for Marseilles, where she is to relieve the *Eurine*, ordered home for repairs. The average speed attained was 11·229 miles an hour, the maximum with the tide being 13·235 and the minimum against the tide 9·118. The *Ellora* has been fitted with Lamb and Summer's boilers.

NOTES FROM SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

Steamers for Copenhagen: Other Shipbuilding—State of Trade in Clackmannanshire and Fifeshire—The Growth of Glasgow—Scottish Railway Traffic—Private Telegraphs—Additional Fire Plugs for Glasgow—The Pig Iron and Coal Trades—Alford Valley Railway—Railway Dispute—Kirkwall Harbour Bill.

Messrs. Caird and Co., Greenock, have just launched a screw steamer of 300 tons, for a Copenhagen firm. She has been named the *Freia*, and will be propelled by a pair of full-powered direct acting engines, her speed being anticipated at 11½ knots an hour. Messrs. Caird and Co. will also launch in about a week a paddle steamer for the same owner, to be named the *Aalborg*, and to be fitted with engines of 60-horse power. Messrs. Denny, Brothers, Dumbarton, have received an order for an iron tug intended for the navigation of the Indian rivers. Messrs. J. Reid and Co., Port Glasgow, have contracted for building two large steamers, including ten barges, for the Oriental Steam Company.——It is stated that the woollen manufacturers of Clackmannanshire have not enjoyed so prosperous a season as the present for many years. Trade in Fifeshire, on the other hand, is reported to be languid. "Mill spinners," says a local journal, "are adopting measures for lessening the production of yarns, and many mills are now open only four days a week. In linens, very few transactions have been conducted."—— From some interesting tables prepared by Mr. Andrew Scott, late of Her Majesty's Customs, it appears that the Glasgow customs revenue was £469 in 1800, £19,434 in 1810, £11,428 in 1820, £72,053 in 1830, £472,563 in 1840, £645,669 in 1850, and 803,356 in 1858.——The increase of Scottish railway traffic was £1,313, as compared with the corresponding period of 1858.——The proprietors of the St. Rollox Ironworks have caused a telegraphic wire to be laid between their Glasgow establishment and the works at Motherwell. This is the first adoption of the private telegraph system in Glasgow.——The Glasgow police committee have made arrangements for laying 1,800 additional fire plugs in various parts of the city.——The pig iron market was slightly lower towards the end of last week, but on Monday it was rather firmer, mixed ores being quoted 51s. 6d. to 51s. 9d.; No. 1 g. m. b., 50s. 6d. to 50s. 9d.; No. 3, 50s. 3d. to 50s. 6d.; Gartsherrie No. 1, 54s. 9d. to 55s.; American Brands No. 1, 52s. to 52s. 6d. Last week's shipments were 3,249 tons foreign, and 4,990 tons coastwise, making a total of 8,239 tons against 11,472 tons in the corresponding week of last year. Coals have continued in limited request both for shipping and home use.——A party of gentlemen have passed over the Alford Valley Railway prior to its being inspected by the government, with a view to the opening for traffic. The run between Alford and Kintore occupied about 50 or 60 minutes.——A dispute has arisen between the Stirling and Dunfermline and the Edinburgh and Glasgow Railway Companies, with reference to certain waste lands on the Stirling and Dunfermline line and along the branch to Tillicoutry. The extent in dispute is about 20 acres, and the Dunfermline Company maintain that in giving up their line to the Edinburgh and Glasgow Company they did not also give up to them the land in question. The difference has been referred to arbitration.——The Lords of the Admiralty have assented to the works proposed to be carried out under the provisions of the Kirkwall Harbour Bill, on condition that plans, sections, and working drawings are approved by them before the commencement of operations. This is the usual stock condition.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated October 19, 1858.

2328. E. Walker, of London-st. An improved filter. A communication.

Dated December 27, 1858.

2960. J. Davies, of Liverpool, Provision Merchant. An improved portable self gas generating lamp. A communication from J. L. Butler, of Brooklin.

Dated January 14, 1859.

123. M. A. F. Mennons, of Paris. A new or improved time-measurer. A communication from P. Perelli-Ercolini.

Dated January 19, 1859.

158. J. Thornton, of Cleckheaton, Machine Maker. Improvements in carding engines.

Dated January 20, 1859.

175. T. Greenwood and J. Batley, of Leeds, Machine Makers. An improvement in the process of gassing textile fabrics. A communication from H. Van den Berghe, of Courtrai, Belgium.

Dated February 4, 1859.

314. M. Smith, of Heywood, Machine Maker. Certain improvements in looms for weaving.

328. J. Honeyman, of Glasgow, Miller. Improvements in the construction of ships, vessels, and boats, and in propellers for propelling the same.

330. W. Clark, of Chancery-lane. Improvements in the means or apparatus for preserving grain, flour, eggs, and other vegetable and animal substances. A communication from L. J. Chateau, of Paris.

Dated February 7, 1859.

339. J. Holroyd, of Leeds, Cloth Finisher. An improvement in apparatus used in finishing woollen and other cloths.

341. W. H. Crispin, of Stratford, Copper Smelter. An improved atmospheric and hydraulic engine for sailing and steam vessels.

343. J. Lee, of Lincoln. Improvements in the manufacture of cranks for steam engines and other purposes.

345. E. T. Hughes, of Chancery-lane. Improvements in ovens. A communication from Herr Von Langen, of Berlin.

347. J. Wilson, of Sunderland. Improvements in ventilating mines, and in combining apparatus used for such purpose.

Dated February 8, 1859.

349. E. T. Hughes, of Chancery-lane. Improvements in machinery or apparatus for sorting and numbering the threads or filaments of silk or other fibrous materials. A communication from F. Mainardi, of Lyons.

351. G. Thomas, of Paddington, Plasterer. A double bottomed horse-shoe.

355. J. Aspinall, of Great Tower-st., Civil Engineer. An improvement in the refining of sugar.

357. A. Clark, of Gate-st., Lincoln's-inn, Engineer. Improvements in revolving shutters and blinds, and in apparatus connected therewith.

359. T. S. Cressey, of Homerton. Improvements in machinery used in the manufacture of casks.

Dated February 9, 1859.

361. E. Wilkins, of Camberwell-road, Gentleman. Improvements in flower vases.

362. J. S. Joseph, of Rhostyllan, near Wrexham. Improvements in coke ovens, and in cooling and extinguishing coke.

363. W. Archer, of Bolton, Jacquard Machine Maker. Certain improvements in Jacquard machines.

364. H. Jefferies, of Birmingham, Button Maker. An improvement in castors.

365. J. Crossley, of Halifax. Improvements in the means employed when steaming printed yarns.

366. J. Taylor, of Stalybridge, Machinist, and C. Wild, of Oldham, Doubler. Improvements in self-acting mules for spinning and doubling.

367. J. H. Johnson, of Lincoln's-inn-fields. Improvements in fire-arms. A communication from W. H. Bell, of Washington.

369. J. E. McConnell, of Wolverton, Bucks, Civil Engineer. Improvements in steam boilers and in the generation and treatment of steam.

370. W. E. Newton, of Chancery-lane. An improved mode of bleaching and purifying, or refining sugar and vegetable juices or extracts. A communication from E. Rousseau, of Paris.

371. E. Herring, of Weybridge. Improvements in the mashing and fermenting of grain for the production of alcohol.

372. W. E. Newton, of Chancery-lane. Certain improvements in breech-loading fire-arms, and in cartridges to be used in such fire-arms. A communication from G. Smith, of New York.

Dated February 10, 1859.

373. H. P. Burt, of Charlotte-row, Mansion-house. Improvements in railway carriages and waggons.

374. J. Young, of Wolverhampton, Manufacturer. An improvement or improvements in the construction of knobs and the roses used for connecting knobs with doors, and with the cases of locks and latches, and other like fastenings.

375. J. G. Taylor, of Glasgow, Merchant. Improvements in writing materials, and the manufacture thereof.

377. R. J. Ellis, of Liverpool, Merchant. Improvements in the apparatus for lifting sunken vessels and other submerged bodies.

379. H. Inger, of Red Lion-sq., Commission Agent. The improvement of blinkers used by horses whilst drawing, to be called the "Patent Safety Blinker." A communication from E. Souché, of Paris.

381. C. L. Perry, of Marcham, Berks. An agricultural implement for paring and ploughing land.

Dated February 11, 1859.

382. M. Billing, of Birmingham, Stationer, and W. Kloen, of Ashton, Commercial Traveller. A method of, and apparatus for, decolourising tea.

383. J. Evans, of Liverpool, Coach Builder. An improvement in "Hansom" cabs.

384. J. Parkinson, of Manchester, Dentist. A certain improvement in coffins.

385. N. Bennett, of Furnival's-inn, Gentleman. Improvements in the construction of brooms or brushes for sweeping or cleansing streets, roads, and thoroughfares, also applicable to domestic purposes.

387. G. Hyde, of Fleet-st., Stationer. A pen for producing a copy or copies of a letter or other writing simultaneously with the production of the original.

388. R. Cogan, of Red Lion-sq. Glass Dealer. Improved instruments for crushing and mixing solid and liquid substances.

389. H. A. Bartlett, of Thetford. Improvements in machinery to be used with or without the plough for clearing and cleaning land from weeds.

390. C. Jackson, of Store-st., Bedford-sq., Pianoforte Maker. Improvements in the action of pianofortes.

391. J. Grimes, of Whitechapel, Pewterer. Improvements in beer engines.

392. H. Ransford, of West Brompton. An improvement in building ships and other vessels.

Dated February 12, 1859.

393. G. Hadwen, of Audenshaw, Lancaster, and J. Wadsworth, of Droylsden. Improvements in Jacquard apparatus applicable to power looms.

394. H. Lea, of Birmingham, Engineer. Improvements in changing or reversing motion.

395. T. Willis and G. Chell, of Longsight, near Manchester, Machine Makers. Improvements in machinery for spinning, twisting, doubling, and winding yarns and threads.

397. J. Crabtree, of Bradford, Commission Agent. Improvements in the manufacture of bobbins and spools.

398. S. H. Huntly, of Upper Baker-st. Improvements in cooking apparatus.

399. T. White, of Portsmouth, Shipbuilder, and G. Jenkins, of the same place, Engineer. Improvements in apparatus for raising and lowering ships along inclined slips.

400. J. and J. Bennett, of King-land-road, Engineers. An improvement in refrigerators for cooling beer and worts.

401. G., G. W., and J. Betjemann, of Upper Ashby-st., Desk and Dressing-case Makers. Improvements in book slides.

402. W. G. Rawbone, of Gloucester-st., Gun Maker. Improvements in fire-arms and ordnance.

403. G. T. Bousfield, of Brixton. Improvements in revivifying the scarlet colour of woollen cloth, lace and embroidery, in use for military and other garments and furniture. A communication from Messrs. Andrès, Burdell, and Chicard, of Paris.

404. H. Gardner, of Old Quebec-st., Portman-sq. Improvements in machinery for breaking and preparing flax and other fibres.

405. R. Bell, of Paris. Improvements in separating and recovering wool from fabrics composed of wool, or wool in connection with cotton and other vegetable substances.

406. W. E. Newton, of Chancery-lane. Improvements in breech-loading fire-arms. A communication from J. H. Merrill.

407. W. E. Newton, of Chancery-lane. Improvements in sewing machines. A communication from J. S. Moody.

Dated February 14, 1859.

408. J. Parkinson, of Manchester, Dentist. Certain improvements in coffins.

409. T. Hunt, of Crewe, Engineer. Improvements in steam boilers or generators, and in the prevention or combustion of smoke.

410. C. Sanders, Photographic Mat Maker, of Birmingham. Certain improvements in ornamenting English passe-partouts for photographic pictures, also the glasses used with the same, and which said modes of ornamenting are also applicable to ornamenting photographic frames generally.

411. J. Wright, of Sheffield, Spring Manufacturer. Improvements in reducing and rolling steel and iron wire, and other forms of those metals in long lengths.

412. J. L. Clark, of Haverstock-hill. Improvement in the means of working railway signals and switches.

413. J. Copcutt, of Kirby-st., Hatton-garden. Improvements in obtaining light from gases.

414. R. Clegg, of Islington, F. Angerstein, of Kennington, and J. W. Page, of Walworth-road. Improvements in making soap.

415. A. B. Clarke, of Edward-st., Blackfriars-road. Improvements in discharging sewage and water from lands into tidal rivers, and in flooding lands therefrom, also conveying sewage and other waters or liquids across canals and over structures, part of such said improvements being applicable as a substitute for sluice cocks and valves.

Dated February, 15, 1859.

416. E. H. Aldrich, of Shoreditch. Improvements in ladies' dress caps.

418. R. Mushet, of Coleford, Metallurgist. Improvements in the manufacture of steel, iron, and cast steel.

420. W. Raymond, of Albion-sq., Dalston, Master Mariner. An improved life-raft.

422. J. T. Jones, of Glasgow, Machinist. Improvements in sewing machines.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, March* 1, 1859.)

2328. E. Walker. Filter. A communication.
2335. W. E. Newton. Springs for railway carriages. A communication.
2339. W. Riddle. Packing bales.
2341. R. D. Clegg. Screws.
2348. J. and S. Marland. Power looms.
2356. E. and E. Palmer. Cutting hay, &c.
2369. R. Bodmer. Toy. A communication.
2374. E. Cottam. Carriage fittings.
2377. F. Fowke. Umbrellas and parasols.
2380. W. Craddock and J. White. Harness hames.
2385. A. V. Newton. Pulverizing, kneading, &c. A communication.
2391. A. P. A. Beau. Stereoscope.
2395. G. Speight. Plaints and curls.
2403. J. Westerby. Lubricating cylinders.
2404. C. Pooley. Carding engines.
2413. W. Kirrage. Substitute for wood, metal, &c.
2420. R. W. Chandler and T. Oliver. Agricultural apparatuses.
2429. G. Davies. Weaving. A communication.
2432. J. Dobson and D. Pearce. Bird cages.
2533. A. V. Newton. Securing doors. A communication.
2566. W. Clark. Treating wood and marble. A communication.
2567. W. Clark. Advertising. A communication.
2717. J. H. Johnson. Locomotive engines. A communication.
2750. F. Fincham. Annealing kilns or ovens.
2907. T. S. Woodcock. Index. A communication.
2978. H. Hutchinson. India rubber goods.
2980. A. V. Newton. Reaping and mowing. A communication.
95. J. Gibbons. Fixing knobs.
166. W. Poupard. Wheel-skid or shoe.
195. A. J. A. Gautier and J. G. Dumay, and J. T. Persin. Manure.
235. W. R. Alexander. Furnaces, &c.
277. H. J. Newcombe. Heating buildings.
280. J. Grimond. Hearth rugs.
322. G. H. Baylis and F. Robinson. Liquid meter.
355. J. Aspinall. Refining sugar.
369. J. E. McConnell. Steam boilers.
383. J. Evans. Hansom cabs.
406. W. E. Newton. Fire arms. A communication.
409. T. Hunt. Steam boilers.
422. J. T. Jones. Sewing machines.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed February 25, 1859.

1942. W. Esson.
1948. J. Fowler, jun., and R. Burton.
1949. R. Knight.
1955. G. Weedon and D. W. Rice.
1959. J. Brazil and J. McKinnell.
1960. G. Davies.
1961. J. Brazil and J. McKinnell.
1963. J. Oxley.
1964. G. Jones.
1965. J. L. Clark, F. Braithwaite, and G. E. Preece.
1966. E. Lindner.
1970. E. Spary.
1976. D. and J. Heyworth.
1981. P. D. Margeason.
1992. J. Walker and J. Barnes.
1998. J. Robertson.
2008. D. Andrew.
2018. J. Shanks.
2032. W. Parsons.
2034. W. Parsons.
2040. W. Prisley.
2045. T. Timms.
2086. R. Lakin and J. Wain.
2107. J. G. N. Alleyne.
2122. A. V. Newton.
2154. M. A. F. Mennons.
2519. J. Buchanan.
2537. J. Buchanan.
2580. S. Hoga, W. P. Piggott, and S. Beardmore.
2818. W. E. Wiley.
2896. J. Kerr.
2936. J. Whitelaw.
2950. J. H. Johnson.
2969. J. Leek.
2998. J. H. Johnson.

Sealed March 1, 1859.

1984. W. Hobbs.
1994. J. Bleakley.
1997. J. M. Bellinger.
1999. W. Harkes.
2002. R. A. Brooman.
2005. R. A. Brooman.
2010. H. Hyde.
2014. J. Fielden.
2016. R. A. Brooman.
2020. J. Fyfe.
2024. F. W. Brind.
2082. J. Luis.
2123. J. Dewrance.
2441. N. Brough.
2460. E. Fielding.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

460. E. Schischkar.
466. T. G. Messenger.
467. R. B. Jones.
469. J. Warburton.
470. H. Loveridge.
492. P. and F. Schäfer.
497. G. T. Bousfield.
505. T. T. Jopling.
506. F. P. Walker.
509. I. Westhorp.
512. J. Fowler, jun., and D. Greig.
513. E. T. Archer.
529. H. A. Dewar.
730. A. Tolhausen.
893. A. V. Newton.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

483. W. S. Clark, of Cannon-st. West. Improvements in the formation of cast-iron rails for city railways, and also in the method of uniting the ends of two adjacent rails for railway use. A communication from S. A. Beers, of Brooklyn. Dated February 22, 1859.

LIST OF SPECIFICATIONS, &c.

Published during the week ending February 25, 1859.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 1479, 1495, 1514, 1517, 1532, 1535.

BOILERS AND THEIR FURNACES, 1478, 1479, 1495, 1510, 1516.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1480, 1487, 1533.

SHIPS AND BOATS, including their fittings, 1511, 1512, 1518, 1529, 1542, 1545.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines. *None.*

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1485, 1493, 1498, 1530, 1536.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1484, 1486, 1490, 1521, 1527, 1543, 1544, 1547.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 1502, 1504, 1519.

LIGHTING, HEATING, AND VENTILATING, 1488, 1494, 1504, 1530.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1506, 1508, 1516, 1523.

METALS, including apparatus for their manufacture, 1481, 1489, 1507, 1524.

CHEMISTRY AND PHOTOGRAPHY, 1501, 1505, 1526, 1534.

ELECTRICAL APPARATUS, 1483, 1491, 1520, 1538.

WARFARE. *None.*

LETTER PRESS PRINTING &c. *None.*

MISCELLANEOUS, 1482, 1486, 1492, 1496, 1499, 1500, 1503, 1509, 1513, 1515, 1522, 1524, 1525, 1531, 1537, 1539, 1540, 1541, 1548.

1478. J. KINGSLEY. *Improved mechanical arrangements applicable to preventing the sudden bursting of steam-boilers.* Dated July 1, 1858.

This consists of the following arrangements:—A large aperture is cut in the upper region of the boiler, and a lid, its upper surface being an inclined plane, rests closely upon the aperture. A weight is laid upon the inclined plane, having rollers to facilitate its moving off the inclined surface. One extremity of a wire is fastened to the weight, the other to the safety valve. A tube is fitted upon the
